AN  
ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

*W. Robinson, Author of the "English Flower Garden."*

"You see, sweet maid, we marry  
A gentler scion to the wildest stock ;  
And make conceive a bark of baser kind  
By bud of nobler race : This is an art  
Which does mend Nature,—change it rather: but  
The art itself is nature."

*Shakespeare.*

# The GARDEN.

VOL. XLVII.

## ORCHARD AND FRUIT GARDEN

### NOTES ON GRAPES.

"C. N." at page 493 has some remarks on judging Grapes, which are of some importance to gardeners and others who exhibit Grapes, but they go further than this, for they open up, as it were, the whole question of judging. "C. N." adds: "Perhaps the judges were not acquainted with the quality of Royal Vineyard Grape, but they might soon have become so by tasting a berry or two." The contention is that the Muscat Grapes were inferior in quality to what Muscats ought to have been, and that the bunches of Royal Vineyard were good, well-finished bunches, while, to add to the other defects, many of the berries of the Muscats were shanked. Clearly, from the description given by "C. N.," Royal Vineyard should have been first, assuming that the prize was awarded, as it certainly ought to have been, for excellence of culture, for in truth Muscat of Alexandria is not such a very difficult Grape to manage, and if the fruit of it is but second or third-rate, it is no credit to the gardener. Of course, everything being equal, that is, the Muscats the best of their kind and the Royal Vineyard also of supreme quality, the latter would be almost sure to take a second place; but the matter assumes quite a different complexion when the Muscats are poor for Muscats, and the Grapes, whether Royal Vineyard or any other, superior in quality. The judges ought certainly to give the prize to the Grapes which give evidence of the most skilful culture. Most Grape growers will, I opine, back me up when I assert that it is more difficult to grow and finish off Royal Vineyard than it is the Muscat. The Vine itself is very vigorous, but the Grapes do not always set well; in fact, never, unless they have special treatment when in bloom. They require a minimum temperature of between 65° and 70° at that critical period; moreover, if the flowers are examined, the stigmatic portion of each will be quite covered with a globule of water, and if the hand is drawn over the bunch it will become quite wet. This must be done daily, as the globules are removed by this process, the pollen becomes attached to the stigma, and the fruit sets well. There is not much difficulty until the autumn, when the berries will crack badly close to the foot-stalks unless a dry,

rather warm atmosphere is maintained. All this demands a good deal of care and watchfulness, so that the gardener who shows good even bunches and berries of Royal Vineyard should be commended. I am well aware that Muscats also require care when they are in bloom and to be artificially fertilised, but the Grape and the details of its culture are well known to gardeners. It is certainly a great relief to judges when two classes are provided for white Grapes—one for Muscats and one for any other variety, because as a matter of fact no white Grapes can beat the old Muscat of Alexandria, all other conditions being equal; therefore, it is rather hard upon a gardener who may be a first-class Grape grower, but who does not grow Muscats, to find he has no chance to win when good Muscats are placed against any other white variety. I bought a plant of Royal Vineyard the first year it was sent out and have grown it under various conditions since, and my experience has led me to the conclusion that when it is well grown there is no other white Grape, except the Muscat, to equal it. It is never satisfactory unless it is managed as I have described above. I have tried Trebbiano, the Syrian and White Tokay, but have discarded all of them in favour of Royal Vineyard. Muscat of Alexandria has an entire house to itself. I used to grow Cannon Hall Muscat in this house, but it is too uncertain and has been discarded. It is now generally admitted that there is but one variety of Muscat for garden purposes, and the name Muscat of Alexandria has priority. The names Bowood Muscat, Tynningham Muscat, Tottenham Park Muscat, &c., are either seminal varieties differing in no respect from their parent, or the names have been given when the variety has done better than usual, it being supposed that it was owing to a difference in variety, whereas it was merely cultivation. At Loxford Hall some twenty-five or thirty years ago I planted a very fine house with Muscats, it being specially built for that purpose. I propagated my own plants from one Vine, and everything was done to make the Muscats a success, and they did very well. I had one or two Vines which were not required. One of these was planted in a corner of another house. The roots had only about a cubic yard of compost to work into, the Vine itself being trained into a Pine house and on the north aspect. The different conditions of culture had so altered the appearance of both bunches and

fruit that I had no difficulty in passing it off as a distinct variety. The berries always set better and the fruit produced was always superior. I believe Mr. Young, Mr. R. P. Brotherston and others of the correspondents of THE GARDEN who were under me at Loxford will remember this Vine. I do not take any credit to myself, as I never expected great results. I merely mention it as some evidence how old Grapes may be passed off as new on a credulous public. Most of us old gardeners remember Snow's Muscat Hamburg coming out, and subsequently Venn's Black Muscat. I have grown both and do not see any difference between them; both are synonymous with the Black Muscat of Alexandria.

There is some difference of opinion as to the best Grapes to grow in private gardens for home consumption. When I first started on my own responsibility as a head gardener I was eager to grow good Grapes and planted twenty-one varieties. A famous gardener remarked to me at the time that I had better reduce them to two—Muscat of Alexandria and Black Hamburg. These are certainly the two best, but it is better in a large establishment to grow a greater variety. I therefore advise for the early vinery Black Hamburg and one vine each of Buckland Sweetwater and Madresfield Court Black Muscat; for the Muscat house, Muscat of Alexandria only; and for the late house, Lady Downe's Seedling, one or two plants of Royal Vineyard and one or two of Mrs. Pince. Gros Colman, Alicante and Gros Maroc I have found wanting. They require more heat than the others; in fact, Gros Colman needs a house to itself to do it well, and it is not worth it. Of course, Grapes for market are a different matter. I am well aware of the popularity of Gros Colman as a market Grape. How long this popularity of certain inferior fruits may last is another matter. No Grape either for quality or long-keeping properties can vie with Lady Downe's Seedling. I have had it in capital condition since November, and it will last until May; indeed, I have had fairly good fruit in June, but it is not wanted after May. J. DOUGLAS.

**Pear Duchesse de Bordeaux.** — This Pear is very little known. I saw it in splendid condition this season trained against a wall, very small trees bearing freely. This is a January Pear, therefore more valuable. It is of a rich melting flavour, and was given a first-class certificate by the Royal Horticultural Society. It was shown at the Pear conference at Chiswick and

much admired. The fruits are above medium size, yellow, and covered with russet spots. Some very fine dishes were shown at the recent fruit exhibition at the Crystal Palace.—S. H. B.

**Grapes cracking.**—A fertile source of cracking in some Grapes is pointed out at p. 495, but "J. C. B." rather exposes his own want of attention, and does not quite clearly point out how to avoid cracking. The only two varieties known to me as liable to crack are Madresfield Court and Royal Vineyard. Allowing Vines to become over-dry at the roots before the Grapes have swelled to their full size is a mistake no good gardener would make. "J. C. B." did this, and did the very worst thing he could do—gave the Vines "a good soaking." No wonder the toughened skins burst. Vines should be well watered all through the growing period, and the last watering should be thorough and given as the Grapes begin to colour. By this treatment no check can be possible; the roots never have been anything like dry, and the thorough watering when colouring begins will carry them well through the ripening stage. All that is required to prevent cracking is to keep a dry atmosphere with ample ventilation in the house. The White Frontignan is not very liable to crack (Chasselas Musqué is probably the variety meant); it is a delicious Grape, but scarcely worth the trouble required to keep it from cracking.—J. DOUGLAS.

#### THE PREMATURE RIPENING OF PEARS, FLAVOUR, &c.

This subject has been commented on in the gardening press, and also been a matter of conversation among fruit growers for some time past. Premature or early ripening is likely to continue until the end of the Pear season, for now (a week before Christmas) I have Beurré Rance ripening. This variety on the average does not mature fully until the end of January. In my case this late Pear always ripens well from free-grown pyramids 12 feet to 15 feet in height; the fruits, it is true, are usually somewhat below the average in size, but this is an advantage rather than otherwise for their perfect maturation. This season the fruits of both Beurré Rance and Josephine de Malines are smaller than last year with me. One might reasonably have assumed it to have been quite the reverse, judging from the character of the two summers. Last year these Pears ripened at their usual time; this year, as before stated, they are much earlier. I am disposed to attribute this earlier ripening not so much to this past season as to the previous one, when, as we know quite well, both the drought and the unusual continuance of hot weather tended, if anything, to over-ripen the wood of fruit trees. This I believe to be the cause of the fruit this past season ripening prematurely. I cannot in any way attribute it to the additional rainfall or the cooler weather during its growth. I think it is rather to be sought for, as I have indicated, in the previous conditions which tended to produce this season a fruitful rather than a woody growth. The influences at work to cause such a thorough ripening of the wood act also upon the roots, causing these latter to be of a more fibrous character. Next year I shall expect to see Pears making a stronger growth, by reason of the recent rainfall. I noted particularly that both of the aforementioned Pears this season were ready to gather nearly as much in advance of the usual time as they are now in ripening. In the case of Beurré Rance this was particularly noteworthy, the crop of which was excellent, all seeming to mature for gathering simultaneously—so much so, in fact, that they had to be handled with great care to prevent them falling. Josephine de Malines hung ten days or a fortnight later than the foregoing. Anent the

former of these Pears, I note that a well-known pomologist in his catalogue advises a wall (south or west). With not the best possible locality I have always had the most satisfactory results from trees in the open—so much so, that my wall trees of Beurré Rance are no more, having given place to dessert Plums. The finer fruits, I readily admit, would be obtained from wall trees, but what is the use of these finer fruits if they will not after gathering ripen perfectly for the dessert? They can of course be used for stewing—that is one way out of the difficulty—but for kitchen use give me either Catillac or Uvedale's St. Germain over all others. The increased attention given to growing what may be termed exhibition fruits has not caused any advance in flavour (perhaps of the two, otherwise, through coarseness); it has rather tended towards size, which I readily admit is only attainable by skilful culture and attention; but after all, extra large fruits, such as usually win the premier prizes, are not such as find the most acceptance upon the dinner table. I do not for one moment justify what may be deemed small or inferior examples; to strike the medium is not a difficult matter.

Whilst on this subject I am led to think of one Pear in particular, viz., Marie Louise, of which I have repeatedly noticed that the best in point of flavour are the russety brown ones from pyramids or other trees in the open as compared with the finer, but more tender skinned examples from walls. Is not this difference to be attributed to the gain in the former instance by the much more free circulation of air going on around the fruits? I think it is only reasonable to assume this to be the case. I have noticed this same tendency in point of flavour in Williams' Bon Chrétien and in a Pear that is too much condemned in regard to flavour Beurré Clairgeau, medium-sized fruits of which are much the best. On the whole I am disposed to think that the Pear is not looked upon as being so hardy as it actually is. I am well aware that the climate of the Channel Islands is most favourable to the production of fine fruits both from the point of quality and size, but, situated as these said islands are, I am very doubtful if these characteristics can be attributed to the additional warmth so much as to the genial breezes which blow over them. Pear trees this season bid well for blossom next year, more so in fact than I should have thought, taking into consideration the late growth that many trees made.

SOUTHON.

### TREES AND SHRUBS.

#### THE BAMBOO GARDEN.

**PHYLLOSTACHYS BAMBUSOIDES.**—The innumerable claimants to this title have been finally sent out of court as impostors now that the real Simon Pure has been received from Hong Kong; and now that it has arrived it appears to have all the characteristics of an Arundinaria, but Phyllostachys it has been named by Munro, and Phyllostachys, I suppose, it must remain. The stem, which is said to grow to a height of from 10 feet to 12 feet, is round and much branched, purplish in colour, and slightly zigzagged; the nodes are thick and smooth, the branches are much knotted, short, and semi-verticillate. The leaves are bright green above, 5 inches long by 1 inch wide, but very variable in size; they are sharply serrated on both edges. The leaf-sheaths are furnished at the top with conspicuous bristles, which fall off with age. The plant has every appearance of proving a valuable addition to our collection of hardy Bamboos, but the specimens which I have seen are as yet mere babies.

**PHYLLOSTACHYS AUREA.**—The distinctive name aurea is not very happily chosen, for there is nothing golden about the plant unless it be the yellow stems, and these are not peculiar to the variety named. *P. aurea* is not a great favourite of mine, as it lacks the grace which is the chief ornament of the family. The stems are very straight and erect in this country, growing close round the base of the plant, which gives it the appearance of having caespitose roots; whereas it has a true rhizome, which in its native climate runs freely. It is seen at its best when planted in bold masses, as the individual plant by itself has too much of the shape of the birchen rod of an old-fashioned dame's school in the kingdom of Brobdingnag. A distinguishing feature of this species is the shortness of the internodes at the base of the stem. The leaves vary much in size, some being about 4 inches long by half an inch wide, others from 6 inches to 7 inches long by an inch or even more broad. The petiole is well defined, the insertion of the young leaves very hairy. One edge of the leaf is conspicuously serrated, the other very slightly, the teeth on this edge being placed irregularly and at great distances apart. Both surfaces are glabrous. At Shrubland, in Lord de Saumarez's garden, *Phyllostachys aurea* is 14 feet 6 inches high, the canes being 2½ inches round. Last year, 1893, a Bamboo was received here and at Kew from Japan under the name of *Bambusa sterilis*, which the Japanese Gardeners' Association describe as closely allied to *Phyllostachys heterocycla*. This appeared to me to be undistinguishable from *Bambusa aurea*, and Messrs. Watson and Bean now share my opinion. Curiously enough, the plants were covered with an undeveloped inflorescence, which proved to be infested with a hitherto undescribed ergot. I may here note once more the great confusion which has prevailed in the descriptions of several of the *Phyllostachys* tribe. *Aurea*, *mitis*, *Quiloi*, *Henonis*, *viridiglaucescens*, *flexuosa* have all been jumbled up in the most hopeless tangle. This has been due partly to the fact of plants being sent out by dealers under any and every name, partly to the eagerness of collectors to describe plants before time had enabled them to develop their characteristics. In a young state *P. aurea* is hardly to be distinguished from *P. mitis*, but as they grow older each puts forth its distinctive features and asserts its identity. Messrs. Rivière remark that, like as the two plants are in their early stages, *mitis* never degenerates into *aurea*, nor does *aurea* ever rise to the dignity of *mitis*.

**PHYLLOSTACHYS MITIS.**—This is the tallest and, in that respect, the noblest of all the Bamboos capable of being cultivated in this country. At Shrubland the culms of plants imported seven years ago are 19 feet 5 inches high and 4½ inches in circumference. In China and Japan it grows to 60 feet high. The stems, which spring straight out of the ground like spears, are, when fully developed, beautifully arched, and have for that reason a grace which is not to be found in *P. aurea*. The young shoots when they first appear above ground seem to hang fire for a while before taking their upward growth. When once they start they are very rapid, growing in this country as much as 6 inches in the twenty-four hours. The utmost growth that I have noticed is 4½ inches in the twenty-four hours; but mine are young plants. Messrs. Rivière have made most interesting experiments on the growth of Bamboos, of which they give tables. The maximum growth of an adult plant of *Phyllostachys mitis* during twenty-four hours in Algiers was 20 inches. They note that *P. mitis* grows most during the night, whereas the other plants of similar growth such as *viridiglaucescens*, *aurea*, *nigra*, &c., make their chief growth during the day. *Bambusa Tulda*, in Bengal, is said to grow as much as three centimètres (upward of 1½ inches) in an hour. As in *P. aurea*, the leaves, which vary much in size, are serrated on one edge, the teeth being almost if not quite absent on the other. The petiole is shorter than in *aurea*, and the hairy growth at its insertion less conspicuous. The sheaths differ much in

colour, but are generally brownish and spotted with purple. As the branches are developed the withered sheaths drop off, leaving a shining deep green stem which gradually ripens into a bright yellow. The branching begins at the base, and as soon as it is thoroughly active the growth of the culm ceases. The underground procession of the rhizome is much more marked than in *P. aurea*, the stems appearing alternately along its course. Although its running powers are in this climate not great, still, whereas in *P. aurea* there is a caespitose appearance, in *P. mitis* the rhizomatous character is well maintained. The young shoots of this Bamboo are eaten in China and Japan. Some gastronomers profess to detect in them the taste of *Asparagus*; this, I confess, demands some faith. The consistency is crisp and pleasant, like *Celery*, but the flavour depends upon the sauce—at least that is my experience. As pickles and sweetmeats they are but poor eating. To its culinary merits, such as they are, the plant owes the synonym *edulis*, which is at any rate less foolish than *mitis*.

**PHYLLOSTACHYS SULPHEURA.**—A handsome golden-stemmed Bamboo, which in appearance has great affinity with *P. mitis*, though Messrs. Rivière see a connection between it and *P. flexuosa*. It is far stiffer and not so free a runner as *flexuosa*, while the only difference which I can detect between it and *mitis* is that it is not so tall and has a more brilliantly coloured stem. The other characteristics are the same; indeed, it would puzzle an expert to tell them apart. Messrs. Watson and Bean lean to this opinion. It is perfectly hardy and well worth cultivating, but difficult to obtain. At Shrubland it is growing to a height of 13 feet, with a circumference of  $2\frac{3}{4}$  inches round the stem.

**PHYLLOSTACHYS QUILIOI.**—A very distinct Bamboo, introduced from the north of Japan by the French Admiral du Quilio in 1866. Some writers see a great likeness between this and *P. mitis*, *P. aurea* and *P. viridi-glaucescens*. To me it appears to have a character altogether its own. In the first place it has a far looser habit, the branches are longer in proportion to the culm, the leaves are larger, serrated on both edges and often marked with purple spots on a deeper green ground than is found in the foliage of either of the others; the hairs at the insertion of the leaves are deep purple. The sheaths are most peculiar; they are of a pinkish-brown colour, deeply mottled with purple spots, and, as they fall, reveal a brilliantly polished dark green stem. The culms are more upright than those of *P. viridi-glaucescens*, less compact and more arching than those of *P. mitis* and *P. aurea*; the rootstock is far more active than in either of the two latter species (in this country), while it does not seem to run so much as that of *P. viridi-glaucescens*. I may be in a minority, but I see in *P. Quilioi* a Bamboo to be recognised among a thousand; and the many eminent botanists and gardeners to whom I have shown it have without exception come round to my opinion. I cannot help suspecting that those who have described it hitherto have not had the true plant before them. I know that this is the case in one instance, where *P. Quilioi* was actually described from a plant of *P. mitis*. Altogether a notable Bamboo, growing at Shrubland to a height of 18 feet 6 inches, the canes having a circumference of  $3\frac{3}{4}$  inches. Synonym, *Phyllostachys Mazeli*.

**PHYLLOSTACHYS VIRIDI-GLAUCESCENS.**—A most elegant and graceful Bamboo, to which many cultivators give the palm of loveliness. It grows to a great height—nearly 18 feet at Shrubland, 14 feet at Kew—while the slender, tapering culms are not more than 2 inches round. The rootstock is very active, the plant being a great runner, while many of the culms come almost horizontally out of the ground, giving the plant a very wide spread. The leaves are generally about 3 inches or 4 inches long and about three-quarters of an inch across; one edge is serrated, the other only partially so towards the point of the leaf. The petiole is well defined, and short brown hairs encircle the insertion of the leaf. The leaves are of a bright green, in pretty contrast with violet stems, which turn to a yellowish-green. The stem

is much zigzagged. Once established, this is a perfectly hardy Bamboo, but it is not safe to plant out specimens which have travelled: I have lost a large percentage in this way. It is better to pot newly arrived plants and let them remain in a cool house until they have recovered from the effects of their journey.

**PHYLLOSTACHYS FLEXUOSA.**—Messrs. Watson and Bean make this identical with *P. viridi-glaucescens*. On the other hand, Messrs. Rivière, who recognise the similarity, say, "We have not remarked in the spathiform sheaths of this Bamboo the toothed membranous expansions which we have met with in many other species of the same group, notably in *P. viridi-glaucescens*." There is, moreover, the fact that *P. flexuosa* flowered and fruited all over France and in Algiers in 1876, while *P. viridi-glaucescens* did not, and this would seem to indicate a different plant. It is certainly not easy to detect any outward and visible sign of difference between the two. *P. flexuosa*, which must not be confounded with the prickly species described under that name by Munro, was introduced into France from the north of China in 1864.

**PHYLLOSTACHYS VIOLASCENS.**—This is now reckoned to be a variety of *P. viridi-glaucescens*. It is somewhat more tender, the leaves being apt to be cut by frost, which gives the plant an ugly appearance in winter, but with the spring the culms are clothed with new foliage, and after all it is only those shoots which come into existence in the late autumn which suffer. The foliage is rather darker and larger than the type and the plant more straggling, the rhizomes running rampantly. But the most distinctive feature is the deep purple colour of the young stems during their first year. This is lost in the two-year-old stems, which change to a greenish yellow or brown. The plants at Shrubland are 15 feet high and the culms  $2\frac{3}{4}$  inches in circumference. A beautiful plant in its early growth, but on account of the defects mentioned above hardly to be reckoned one of the best of the hardy Bamboos.

**PHYLLOSTACHYS HENONIS.**—To my taste this is the loveliest of all our Bamboos; indeed, it would need the inspiration of a poet to do justice to its beauty. Nor is that its only merit, for it is perfectly hardy and bears up bravely against our rudest and coldest weather. Of all the plants that I imported not one has gone amiss, though they were subjected to hardships to which, now that I know better how to manage, I should not dream of exposing them, and which proved fatal to a good many of their travelling companions. The Shrubland plants are now 14 feet high, the stems  $1\frac{3}{4}$  inches in circumference. The tapering leaves are about 4 inches long and about half an inch across. They are very smooth on the upper surface and ribbed on the lower, serrated on one edge and very slightly on the other. The colour is a pale green and less glaucous on the lower surface than most of the leaves of *Phyllostachys*, the midrib prominent, the petiole well defined. The slender tall stems are green at first, growing yellow with age, slightly zigzagged. The rootstock runs rather freely. But it is to its habit that this Bamboo owes its surpassing loveliness. The two-year-old culms, borne down by the weight of their own foliage, bend almost to the earth in graceful curves, forming a groundwork of the most elegant beauty, from which the stems of the year spring up, arching and waving their feathery fronds, the delicate green leaves seeming to float in the air. I regard *P. Henonis* as the embodiment of every grace to which plant life is heir. The Japanese synonym is *Ila-chiku*, the Chinese characters with which it is written signifying the "light or volatile Bamboo."

**PHYLLOSTACHYS NIGRA.**—This is perhaps the best known, and from its black stems the most easily recognised of the hardy Bamboos. On the Riviera and in Algiers it grows to a height of about 30 feet, the stems being nearly 6 inches round. At Shrubland and at Kew it is 10 feet high and the stems are 2 inches round. With me the plant has been a little capricious and difficult to establish, but once it has taken hold of the

ground no Bamboo seems hardier. The stems are of an olive-green colour during their first year of growth, changing to shining black the following year. They are slightly zigzagged. The leaves, which are from 3 inches to  $4\frac{1}{2}$  inches long by three-quarters of an inch broad, are green on the upper surface and glaucous underneath. The rhizome runs with some freedom. Messrs. Rivière call attention to some peculiarities in the structure of this Bamboo upon which, as they are more interesting to the botanist than to the gardener, it is unnecessary to dwell here. It is enough to say that in *Phyllostachys nigra* we have a plant of striking beauty and undoubted hardiness. It is said that it is the rhizome of *P. nigra* which furnishes the Wanghai cane of emmerée, to which allusion has already been made.

**PHYLLOSTACHYS NIGRO-PUNCTATA.**—A variety of *Phyllostachys nigra*, taller, and a looser and more free grower than the type. The stems, green at first, change in their second year to a dull brown speckled with black. There is no other characteristic to differentiate it from *P. nigra*.

**PHYLLOSTACHYS BORVANA.**—Another and still larger variety of *Phyllostachys nigra*, one of the handsomest and most vigorous of the hardy Bamboos, very graceful in its habit, as indeed are both *P. nigra* and *P. nigro-punctata*. As in their case, the stems are green during their first year, but change colour the second year to a dull brown splashed with large deep purple or black blotches. This and the preceding variety have proved more easy to establish than the type. I have not lost a single plant of either, though they have been subjected to great hardships; whereas *P. nigra*, as I have already said, has been apt to resent rough treatment. One peculiarity of all three varieties is noteworthy. The rhizomes are fond of running very near the surface of the earth, sometimes, indeed, above the surface. When this is detected it is advisable to cover them with a little loose soil, which may be kept down with a light stone. This encourages the verticillate roots to strike downwards. Failing this, I have known the rhizome to be killed back and the development of the plant to that extent retarded.

**PHYLLOSTACHYS CASTILLONIS.**—A most lovely plant, indeed one of the best of the many good gifts which we owe to Japanese gardens. The foliage is larger than it is in most of the Bamboos, some of the leaves being as much as between 8 inches and 9 inches long by nearly 2 inches broad. When they first appear they are striped with bright orange-yellow, which in time fades to a creamy white. Both edges are serrated. The petiole is short, the leaf-sheath dressed with a fringe of long brownish purple hairs. The stem, which is much zigzagged, is bright yellow and green, the latter colour remaining in the deep channels left by the pressure of the branches, so that the two colours are alternate all the way up the culm, the hues being intensified with age. As the sheaths of the branchlets are of a very pretty pink, the plant has a tri-coloured effect, which is most pleasing; the branches come in twos and threes. My plants in their second year have grown to about 6 feet, and have every appearance of attaining a goodly height and proportionate circumference. Twenty-four degrees of frost last January (1894) did them no harm, but M. Marliac tells me that the foliage is apt to suffer from snow. This, however, can at the worst be only a temporary evil. One of my plants is extremely curious as a variation from the type. Not only is the variegation absent from the leaves, which are bright green, but in the stems its position is exactly reversed, the channels being yellow and the rest of the culms green. The Japanese name is *Kimmei-chiku*, "the golden brilliant Bamboo."

**PHYLLOSTACHYS KUMASASA** (*P. viminalis*, Marliac).—A pretty little Bamboo, described by Munro as *P. kumasasa*, though the Japanese name is *lungozasa*. The stems are about 18 inches high, purplish green in colour, with brown sheaths, much zigzagged and very slender, distinctly channelled from the pressure of the branches, which spring in twos and threes, sometimes in fours from the nodes. The leaves are

from 2 inches to 4 inches in length, and an inch, more or less, in width; ovate; soft hairs very conspicuous on the lower surface, but none on the upper surface or on the insertion of the leaves, which are serrated on both edges. By giving the name *kumasaea* to this Bamboo, Munro has given rise to some difficulty. *Sasa* (in composition after a vowel *sasa*) is a Japanese version of the two Chinese words *hsiao chu* (small Bamboo), and is the generic name given by the Japanese to the dwarf Bamboos; *chiku*, another Japanese version of the Chinese word *chu* (Bamboo), and *také*, a pure Japanese word, being the names given to the tall-growing or arborescent Bamboos. *Kuma* signifies an edge or border. The etymology of the word *kumazasa* (barbarously altered by Munro into *kumasaea*) would seem to point to the *Arundinaria Veitchi*, on account of its leaves withering at the edge in winter, and so having an edge or border margin. It is certainly often used in that sense by natives. Japanese botanists, however, apply the name to *Arundinaria tessellata* or *Ragamowski*, while our English botanists, following Munro, give it to *Phyllostachys viminalis*, which the Japanese call *bungozasa*, probably from the province of that name in the southern island. There is thus a triangular duel between science, etymology and common use, which is most bewildering, and so long as this lasts it would seem wiser to leave the Japanese names alone, contenting ourselves with the European nomenclature. But when science does find it necessary to adopt words taken from a foreign tongue with which she is unacquainted, she will do well to avoid altering consonants, as Munro did when he made *sasa* out of *sasa*, or she may get herself into dire trouble. Try it upon a few English monosyllables! Synonym, *Phyllostachys viminalis*.

A. B. FREEMAN-MITFORD.

**Hypericum nepalense** (p. 476).—Surely Mr. Wolley-Dod is wrong in asserting that the plant (shrub) long known in gardens under this name and that grown as *H. patulum* are the same. These plants grow here probably as well as they do anywhere. I have seen *H. nepalense* 10 feet to 12 feet high, while I have never seen *H. patulum* even in the case of long-established bushes more than 3 feet to 4 feet high. In both leaf and flower characters they differ widely, one of the most striking characters of *nepalense* being the brilliant scarlet colour which many of the leaves (not altogether, but one here and there) take on in the autumn, a feature never seen in *patulum*, though it occasionally occurs in the case of *H. oblongifolium*. The late M. Lavalée calls our *patulum* *H. Gumbletoni* (Hort. Segrez), and gives the synonymy as *H. patulum*, Hort. (non Thunb.), *Rev. Hort.*, 1875, *H. nepalense*, Hort. (non Choisy); then he makes *H. uralum* a distinct species, and gives *H. uralense* (Hort.) as its syn.—T. SMITH, *Newry*.

## FLOWER GARDEN.

### GLADIOLI.

WHEN commenting in THE GARDEN some little time ago on the fine development of our exhibit of these flowers at the R.H.S. Gardens, Chiswick, you ask if we give the plants any special culture, or if the delicate coloured varieties are more difficult to grow than the darker self-coloured kinds. As regards the various colours there is little difference, and much depends on the constitution of individual varieties as to whether they increase rapidly or not. Some very fine varieties scarcely produce spawn; consequently are more difficult to grow than others which do so more or less abundantly. Yellow shades of colour are, as a rule, the most prolific. As regards culture, suitable soil, in my opinion, is the most important thing. Nearly all writers on Gladioli lay great stress

on the soil being light and sandy for the *gandavensis* hybrids. Here we grow them in a soil exactly the reverse of this—strong, adhesive yellow loam, which sticks together like putty, and in which not a particle of sand is visible, neither is any mixed with the soil or placed round the bulbs in planting, so common with most cultivators. In place of sand we use a little burnt earth over each bulb, just enough to ensure the new bulb lifting clean in the autumn. Sand is entirely dispensed with here from raising the seed and small bulblets onwards, both of which have a fairly good holding loam from the commencement. A light sandy humus soil I should consider the worst for encouraging disease and failure. Sometimes it is suggested that the ground intended to be planted with Gladioli might with advantage be fallowed the previous summer, and this was the plan adopted by the late M. Souchet, the originator of the fine race of *gandavensis* hybrids, still the most noble and beautiful of the genus. Whilst admitting the advantage most crops derive from this system of cultivation, I fancy few people would care to have bare patches of fallow in their gardens, and even on our own strong loam we have not found it necessary to adopt this plan. Probably M. Souchet adopted the system more with the idea of destroying the cockchafer grub, or *ver blanc*, as it is called in France, so destructive in some parts of his grounds, and to the young stock of Gladioli generally, as we can testify during hot seasons here. The benefit accruing to the soil was probably of quite secondary importance. I believe a similar plan of fallowing the ground is sometimes adopted on some of the Dutch bulb farms, boxes being placed to encourage the nesting of starlings, which greedily devour the cockchafers whenever the ground is freshly broken up and the grubs exposed to view.

### CULTIVATION.

We mostly plant our Gladioli on ground where Roses have been sold off the previous autumn, and during December or January this is thrown up roughly, and advantage taken to turn it over once or twice later to become well pulverised before the planting season arrives. At the final digging we turn in deeply a small quantity of well decayed manure, but are particular that this does not come into contact with the bulb. Planting generally commences towards the end of March or early in April, and continues at intervals over about a month. As soon as growth is well above ground hoeing is commenced, and continued at intervals until the blooming season arrives. Little or no watering is done, but sometimes a few beds are mulched very lightly with short straw. We carefully avoid mulching with rank or decayed manure or applying liquid manure, both of which we consider fruitful sources of disease. Other bad practices are carefully avoided, such as leaving the stems on after lifting the bulbs and laying them away to dry off in this state. Keeping the bulbs in sand or dry earth, or putting numbers together in paper bags until they start into premature growth, which they quickly do, and soon become masses of roots in the bags, arising from the moisture of many bulbs coming into close contact with each other, are common and fruitful sources of failure in Gladioli culture, as is also the practice of adding to the beds turfy loam, which invariably contains wireworm, a most destructive pest to Gladioli. Much has been written about the

### HARDINESS

of Gladioli and the advisability of leaving them in the ground during winter. Here we find the

*gandavensis* and *Lemoinei* varieties are both comparatively hardy if the bulbs are in the ground to a depth of about 7 inches. After severe winters, without protection, we have numbers come up in the spring, which bloom strongly the same year, from bulbs missed in lifting the previous autumn, and which by accident have been dug deeper into the ground than the usual depth of planting. From this it may be inferred that both sections are hardy when planted sufficiently deep in well-drained soil. Especially would this be so near the coast, where frost is less severe than here. Although we leave a portion of our young stock in the ground during winter, I do not advocate the practice generally. Gladioli dislike excessive wet, which is possibly more harmful than frost, and many of the corms have a hollow crown-like basin, which makes it difficult for water to pass freely away. Another drawback is the decay of the old corm in close contact with the newly-formed one from which the following summer's bloom is expected. The old corm as it slowly rots becomes infested with worms and grubs, which in turn frequently attack the new corm, and by this means cause it to become unhealthy. Annual lifting has also the further advantage of allowing the bulbs to be divided and cleaned and of their being replanted in well cultivated soil, matters of much importance in their successful cultivation. Gladioli with us are much the finest in a hot and comparatively dry season. During the early part of the hot summer of 1893 the flowers and spikes were of a size and beauty never previously attained.

We find Gladioli fairly easy to manage, and are able to keep up a healthy stock of most of the old-established varieties, and to increase vigorous stock of any good seedlings forming bulblets, but through lack of this propensity many fine seedlings are slow and difficult to increase. The mole is our greatest enemy, and the depredations of this subtle animal cause more losses than all other evils put together.

If Gladioli do not succeed under certain modes of cultivation and fail in some gardens, might not the same charge be brought against many other garden plants. Take the Carnation as one example. In how many gardens are healthy collections of named varieties of even the more robust border kinds kept up without frequent renewals of fresh stock? I fancy in only a few favoured spots, although the orthodox rules of culture may have been strictly carried out. A large trade grower of these plants recently remarked that he annually provides about 100,000 to meet losses. By varying modes of cultivation, exchange of stock, &c., the specialist overcomes difficulties, and is enabled to provide healthy stock. So with Gladioli. It is, as your correspondent "Enthusiast" states when he quotes the old adage, "That where there's a will there's a way." If it were otherwise, the large trade growers of these flowers would not be able to offer, as they do, by the hundred every season bulbs of sorts which have been in existence for considerably over a quarter of a century. Perhaps the old French variety *Meyerbeer* was never previously exhibited of so fine a size and substance as by us during the past season from stock raised here, yet it is a variety dating back at least a quarter of a century. *Horace Vernet*, a now somewhat old variety, was another notable example of healthy vigour and beauty in old age. There are many other old favourites so easily increased where the cultivation of these flowers is well understood, that they may be purchased anywhere for a few pence each.

Cambridge.

J. BURRELL.

## SUB-TROPICAL PLANTS AT TORQUAY.

The plant that is above all others valuable for sub-tropical gardening is, without doubt, *Musa Ensete*, the graceful sweep and emerald folds of its giant leaves associating themselves naturally with tropic skies and Grass hammocks, and suggesting recollections of the frondage of fruiting Bananas waving listlessly beneath the faint trade wind. Though it is not often that in this much-maligned island we are treated to the weather of the tropics, there are spots in England where during most summers *Musas* may be seen flourishing in the open, the popular seaside town which furnishes the scene of the accompanying illustration being one of them. Many years ago it occurred to certain residents in Torquay that their equable climate—the influences of the tail-end of the Gulf

*Musas*, *Daturas* (*Brugmansias*) and *Hedychiums* luxuriate in the warm autumn weather and have been known to pass through the winter alive. Such a course in the case of these subjects should not, however, be attempted except by way of experiment, as even if they survive they are so late in starting into growth, that they rarely have time to become ornamental before the advent of the next cold weather.

*Musas* should be kept in heat during the winter in order to induce strong growth, shifting them into a cool house in May and planting out in rich soil during the month of June. Care should be taken to disturb the ball of earth as little as possible in planting, as it is important that no check should be received at this juncture. In one garden, where a

whipped into ragged fringes by the boisterous winds of the Mediterranean, as may be seen any spring day at Algiers. S. W. F.

## NOTES ON HARDY PLANTS.

*Gillenia* (*Spiræa*) *trifoliata*.—Of all the *Spiræas*, whether woody or herbaceous, this is perhaps the most difficult to propagate. It makes long, direct, but somewhat crumpled roots that are considerably swollen at their deeper parts, and they are not very fibrous. At any time if the plants lose these roots they suffer a considerable check. There are two ways of propagation that I practise with success. One in the case of young plants that I should not care to lift, the other by means of old plants by root division. In the case of young plants, the young growths may be taken in early summer, and slipped off the wood-stock by a backward wrench. These treated in the ordinary way as summer cuttings make nice little plants for the autumn, but they will be a year or two before they produce flowers in the profuse way for which this species is so justly admired. The division of old strong roots is a more trying business, because the crown is so woody and hard, that you may easily lose the finer crowns by not securing to them their complement of roots. A knife is scarcely strong enough for this operation, so hard is the woody crown. I have to use the hatchet, driven by a heavy hammer. If you succeed in dividing these fairly, the plants may be relied upon to flower as well the first year as cuttings might do in their third, and yet to see this plant in all its beauty it should be left alone for many years without disturbance.

*Gillenia* (*Spiræa*) *stipulacea*.—This, seen growing, somewhat closely resembles *trifoliata*, but there are important differences. The feature implied by the specific name is an almost unnoticeable betanical one. The gardener will sooner notice that it has softer and more procumbent stems and perhaps a less profuse flowering habit. It is in reference to the better facilities for propagation compared with *trifoliata*, of which I have just been speaking, that this plant will show its wider variation. It makes more distinct offsets, so that in the case of plants a few years old you may take the offset roots with a fair amount of fibre, and they make good plants the first year. The *Gillenias* have a distinct and delicate beauty all their own, and are pre-eminently suited for growing in semi-boggy places interspersed with such subjects as the Bog

Lilies, Irises, Bamboos, and other similar strong growers.

**Snowdrops.**—I wonder what these are going to do? By the kindness of Mr. Allen and several other garden friends at home and abroad I am put in possession of a considerable collection, and nearly all thus early are spearing through and showing the fat buds, already becoming distinctly white. We suppose that the winter has yet to begin. No doubt, as usual, when the frosts come they will heave up the soil for nearly an inch, and, it is hoped, will so cover up again these humble, but welcome harbingers of the brighter season.

**Anthericum liliastrum.**—It is true that the St. Bruno Lily never looks better than when grown in bold groups. I have had it in single specimens with seventy or 100 spikes, but with me it invariably reaches a certain point of perfection, and the following year may by comparison be said to be a failure. In such cases I have always found the symptoms the same.

*Musa Ensete* in the garden at Ponsonby, Torquay. Engraved for THE GARDEN from a photograph sent by Mr. Holder.

stream—and the spacious gardens in which for the most part their villas were ensconced, were alike favourable to the growth of sub-tropical vegetation. The experiment was tried, succeeded, and has since become a cult. Now, with their Palms, *Dracenas*, and *Phormiums* many gardens present a Riviera-like aspect, and there are few without some specimen that attests the geniality of the west country atmosphere. *Dracena* (*Cordylina*) *indivisa* and *australis* grow to a large size and flower well. *Chamaerops Fortunei* and *excelsa* attain goodly proportions. The New Zealand Flaxes, both the type and the variegated variety, are thoroughly at home, and throw up candelabrum-like flower-spikes year after year. *Aralia* (*Fatsia*) *japonica* becomes almost a tree in a surprisingly short space of time, while during most summers an *Agave americana* can be found in bloom in the neighbourhood.

great point was made of sub-tropical bedding, a bed of large *Musas* was always the *piece de résistance*. In this instance the plants were grown during the winter in paraffin casks sawn in half, and when put out were wheeled to the sides of the holes prepared for them, the hoops knocked off the tubs, which were then pulled to pieces and the balls gently lowered into their places. The plants were quite 6 feet high when planted out, and never felt the move. The great enemy to the *Musa* is the wind. It is therefore advisable to plant in as sheltered a spot as is available, for should the leaves be much torn, its chief charm is lost.

There are few more beautiful sights than a Banana garden in a quiet valley in some West Indian isle, with every leaf intact and each a harmony of colour, with its soft gradations of green in the mingled sunshine and shade—few more pitiable than a plantation with leaves

Whether a cause or an effect of the lost vigour of the plants is not quite so clear to my mind, but I always find the most densely matted roots more or less cankered, with a strong and disagreeable smell. I take it that the oldest and decaying roots, from their contact, may have contaminated the whole. The stock, however, is by no means lost if dealt with promptly. The mass of roots only needs to be washed out, and all the crowns divided into single ones. These may be reset any time now when the frost is not in the ground, and they respond with remarkable vigour the first year, and, what is more, if these single crowns are placed somewhat closely, the idea of a bold group can be maintained. I have noticed lately that though there are larger forms—majus and giganteum—this, the dwarf type, fully holds its own, and by many is the most esteemed.

**Lithospermum rosmarinifolium.**—This in the open, owing to the continued mild weather, and notwithstanding the two short periods of frost, respectively here 12° and 8°, is now showing bloom, and I was pleased to read Mr. Buxton's notes in these columns a fortnight ago that he had a similar experience. It is an exquisite little shrub. As implied by the name, it resembles a little bush of Rosemary, and the spikes of blue flowers are of a colour only found in the Lithosperms and the Gentials. I think I can venture to recommend the planting of this species in sunny nooks of an otherwise well-exposed rockery, in deep seams of rich soil, where its roots may pierce deeply and never lack the needful moisture. I daresay that in some localities, or planted indiscriminately, it might be killed in very severe winters, but it is quite one of those species that is worthy of a little care, and when I say a little care, I mean no more, because I am quite sure I can keep it out-of-doors in my Yorkshire climate by fixing over it a few sprays of dry Braeken during the severer part of the winter. A more important point to watch is that you do not allow it to be overshadowed during summer, as then the shoots and evergreen foliage would be wanting in the ripeness essential for safety.

**Chrysobactron (Anthericum) Hookeri.**—There can be no better time than the present for dealing with overgrown plants of this. That the plants do become overgrown or—to be more precise—overcrowded is beyond doubt. The root habit is fleshy, twisted, and, with age, much congested. When plants that have been thriving reach the age of five or seven years, it is profitable in every sense of the word to divide them and give them fresh soil. According to my experience the plants attain their greatest vigour and beauty at the age of about four years. After that the foliage and flower-spikes, which may be equally numerous, or even increased, are lessened in vigour, and if you examine the roots of such plants you will readily find the cause. The fine shining coppery-green leaves surround the almost golden scapes, which reach a height of 2 feet, and nearly half that length beset with closely compacted flowers of the true old gold yellow. To anyone not acquainted with the plant it would almost suggest itself as too tender for out of doors, but I think we have no plant more hardy—at any rate, it never suffers from frost, not even the late frosts.

**The Elecampane (Inula Helenium).**—I suppose we may consider this one of our noblest British plants. It attains magnificent dimensions, and I know nothing so appropriate and effective for flanking or backing up groups of Lilies. Established stools in rich land throw up spikes 7 feet high, and the shuttlecock arrangement of the enormous radical leaves is telling to a degree. I have seen them 3 feet to 4 feet long and nearly 1 foot wide. It is needless to describe further to show the many uses that a stately plant like this may be put—in shrubberies as isolated specimens bordering lawns, sunny, but sheltered hillsides, or even the wild garden where there is but partial shade. In every way it is a reliable plant if you give it good deep soil and keep it clear of other plants. For small gardens I should say that it would be totally out of place.

**Meconopsis Wallichii.**—I would not cover this up during the winter in any way that had the least tendency to smother its hairy foliage. If you do so I fear you will find when the covering is removed that the handsome foliage has become more or less decayed; besides, there is no necessity for it. It is perfectly hardy, and during our wettest winters, notwithstanding its hairy covering, it manages to roll off the wet in globules if other material does not come into contact with it. A sheet of glass borne over its head by some contrivance would be different—better—helpful, as in that case there would be no contact. Of course, we must remember it is but a biennial, and that nothing will save plants after they have once flowered. But, beautiful as the pale blue flowers of this species are, I think the yellowish green rosettes of foliage, beset with their long silky hairs, are quite as effective in the first year of the plant's life as the dying glory of its flowers. It enjoys heavy, almost clay-like, loam and a wet situation, with as much sunshine as it can get. Just now and all through the winter it is one of those plants that may be looked upon with pleasure, and which helps to sustain our interest in our gardens until the advent of spring flowers.

**Tulipa sylvestris.**—I do not know why we should take up our Tulip bulbs every year, at any rate those of the species, and I am quite sure that we not only need not do so in the case of this one, but that it will be infinitely more profitable to leave it alone in every way except one, and that is, if you love it, give it room. It may not be generally known that this Tulip spreads itself deeply underground by means of root-stolons, and that is what I mean by saying give it room. I have just had occasion to disturb an old group of seven or eight years' standing, originally formed of but six bulbs, and I found the progeny in a patch some 8 feet or 9 feet across. I ought to say that the land was rich and light and the position as sunny as possible. Everybody ought to grow this Tulip, glistening pale yellow, with casual edgings of red. Very frequently the scapes carry two flowers, but the most valuable property of all is the piquant aromatic perfume. As a flower for picking it is perfect. The bulbs are very small for the size of plant and flower. J. Wood.

Woolville, Kirkstall.

#### FLOWER GARDEN NOTES.

In all operations connected with the annual raising of the stock of summer-bedding plants there is a growing tendency to rely more on those obtainable from seed, and that being so an early inspection of catalogues is imperative, many varieties having to be in by the end of the month to secure good plants. Advantages claimed for seedlings in lieu of cuttings are chiefly that attention for five months in the year is dispensed with, and also that the plan adapts itself to limited accommodation in the way of glass. A lot of August-struck cuttings require a proportionately large share of room; whilst, on the other hand, one small warm house will hold a lot of pans and boxes for seedlings, and by the time these are ready to prick off, pits that have been emptied of the earliest Potatoes, French Beans and Asparagus can be filled with them. A great variety of plants is now obtained in this way; in fact selections from all the different families used for the summer display would be included in the list, herbaceous plants, choice bedders, sub-tropical plants, specialties for particular work, and the best of the annuals. For those not conversant with the proper time for sowing it may be noted that herbaceous plants designed for the formal garden, as, for instance, Antirrhinums and Penstemons, should be sown about the end of February; choice bedding plants, Begonias and Centaureas, for example, early in the same month, most of the sub-tropical plants at the same time, and the commoner bedding plants and the best annuals, Lobelia, Verbena, Petunia, and Zinnias among others, some time in March. Plants for special purposes should be raised so that they can be grown along into nice stuff by the time they are required. Golden rules to be followed in the rais-

ing of all the above plants are to sow carefully and at the proper time, to keep in an even temperature, to prick off as soon as practicable, to grow on quickly, and where necessary to allow a suitable time for hardening off. Where seedlings are used somewhat extensively, it may also be noted that one should be able to thoroughly rely on the strain so as to have the right thing in the right place. A mistake does not matter so much in the wild garden, but is sometimes awkward in small beds in prominent places. Two cases in point that came under my notice last year are illustrations of this. One was a group of small beds planted with a strong growing Petunia, that would have been very fine in a bed some score feet or more square, but that was quite out of character in tiny circles that one could step across, and another case was that of a lot of Antirrhinums that should have gone up quite 2 feet, but that proved pigmy varieties and were flowering at 6 inches. The different types of Begonias furnish material for the same argument. The big-flowered, big-foliaged varieties are doubtless fine for massing in quantity, or as a set-off to a nicely contrasting carpet, but for small beds the semperflorens type is infinitely preferable. I suppose it is matter for congratulation that so many different forms are available. Our giant or California Petunias and strong seedling Verbenas are as useful in their way as the dwarf, compact types. The Centaurea candidissima is probably the best silvery-foliaged plant we have and a long way better than the sickly variegation furnished by some Geraniums, and its usefulness is the more apparent when we find that white-flowering bedders of that size are somewhat scarce. Of course, in dwarfier subjects we have the lovely White Swan Viola and the really excellent novelty White Lady Lobelia, and in taller plants the very useful white Antirrhinum, but the medium size in whites gives us rather shy-flowering subjects, as Pelargoniums, or of miffy habit, as white Verbenas. Taller white flowers, all exceedingly useful in the flower garden in different ways, are the Sweet Tobacco and white Marguerites, with Guiding Star (pompon) and Constance (decorative) Dahlias. These last three, however, would be included in plants raised from cuttings, and are therefore not admissible among seedlings. I have included sub-tropical plants in the list of those obtainable from seed. Only, however, in very large gardens are they required in quantity; the small and average sized places can be furnished from a sowing of Eucalyptus globulus and E. citriodora, Acacia lophantha, Grevillea robusta and a few plants of Nicotiana glauca—a very useful acquisition that comes readily and quickly from seed, is a kindly and quick grower, and an efficient and cheap substitute for large-leaved sub-tropical plants. With the above, if there is much covering of balconies, &c., to be done, may be sown a nice batch of Cobaea scandens, the best and quietest summer climber we have. The seed is best sown singly in small pots, placing it on edge.

**NOVELTIES.**—It is seldom advisable to accept these and plant them the first season in prominent places in the flower garden unless one has previously seen them doing well under similar conditions. Nor is it always advisable in the case of beds of mixed seedlings. Verbenas, Phlox, and Nemesis are generally satisfactory, but such things as Begonias and Petunias are apt to vary considerably and to present in their variety features not consistent with the best type of flower garden arrangements. Of things tried last summer for the first time that have certainly "come to stay" were the semperflorens type of Begonia, Dunrobin Bedder Fuchsia, a capital strain of blue Petunia, and the new Lobelia Bernard's Perpetual and White Lady. There were a few light blue stragglers in the latter variety, but we were careful in propagating and have got it true. A characteristic of this variety would seem to be its winter-flowering properties. The stock plants are now (December 28) quite studded with bloom, and have been gay for some time. One of the best introductions of 1894 was pro-

bably the new yellow *Viola Prince of Orange*. I should say it is likely to rank as about the very best yellow bedding plant of its size in cultivation. We shall take advantage of a wet day early in the year to overhaul the stock of pot plants that are required through the summer months in the immediate neighbourhood of the mansion. Big plants of *Heliotrope*, *Fuchsias*, *Aloysias*, and scented *Pelargoniums* will be thinned out, cut back where required, and some of the top soil removed preparatory to replacing with a bit of good loam and cow manure. A good batch of the variegated form of *Aspidistra lurida* that we find very useful for mixing in with flowering plants is similarly treated. Zonal *Pelargoniums* constitute the bulk of the smaller plants used (they stand the exposed situation much better than large-flowering *Begonias*, *Fuchsias*, and *Lilies*): these are also cut back and top-dressed with a bit of good stuff. They will stand in the same pots for years with this annual top-dressing and the help of manure water in summer only; the drainage must be reduced to a minimum, just one crock, and a small handful of cow manure over the same. A good many varieties are grown, but this is hardly necessary if one has a few good things in the different shades. *Raspail*, *Jacoby*, *Constance*, and *Queen of the Belgians* are four excellent sorts. A capital plant for dotting occasionally among the *Pelargoniums* is *Francoa ramosa*. This has come wonderfully to the fore of late years, and is nearly always to be found in outdoor groups. It should have cool treatment right away from the cutting pot; indeed anything in the way of warmth, especially moist warmth, is, as a rule, fatal to the proper development of the flower-spike. *Campanula pyramidalis* and *p. alba* are also, when well grown in pots, very effective in connection with the outdoor grouping of plants. Some plants of *Nicotiana affinis* in pots are always useful. This is a charming evening plant, and its delicate perfume is much appreciated; it is a worthy companion to the *Heliotropes* and *Aloysias* above mentioned. Sweet Peas in pans for covering a stretch of lattice-work formed a pleasing feature last summer in connection with the grouping of pot plants, and the pans will be cleared and refilled with some good soil ready for early sowing.

GARDEN FLORA.

PLATE 995.

COREOPSIS GRANDIFLORA.

(WITH A COLOURED PLATE. \*)

FOUR years ago when I saw this plant flowering in the nursery of Mr. Thompson, of Ipswich, to whom we are indebted for its introduction, I ventured to predict that it would soon become popular and be extensively grown. It has already found numerous admirers, but doubtless as yet many will not have grown or seen it, and the publication of the accompanying plate, in which its fine size and rich colour are so well shown, will further help to popularise it. It fully deserves its name, as its flowers are very much larger than those of any other *Coreopsis* grown in gardens, whether annual or perennial. When first introduced it was said, on the authority of Dr. Gray, that its blooms were about the same size as those of *C. lanceolata*, but it was not long in cultivation before it produced flowers that altogether surpassed in size and beauty even the best forms of the older *C. lanceolata*. Again, Dr. Gray was undecided as to whether it should be considered an annual or perennial species, and even now it is not possible to make any definite declaration on the point. It is amenable to

treatment as an annual, but then only a late summer and autumn bloom is the result. Perhaps others who have grown it over several seasons will give us some information as to their experience, but it seems to me that the proper course is to treat it as a biennial, certainly so if we want a large bold group of it. If well grown it flowers so freely that it will in the end die. The first group that I grew bloomed from early summer till early winter, but not one plant survived. In two smaller groups of plants raised last year some plants at the present time have strong side shoots that will certainly grow again another year, whilst those that flowered very freely are very weak and in all probability will die. Some may think this discouraging, but the plant produces and ripens an abundance of seed even whilst flowering, and it is advisable if prolonged blooming is desired to keep the faded flower-heads picked off, except such as are wanted for seed. In raising it from seed, slight variations occur as regards the size of flowers, and it will be wise therefore to encourage and save seed from the finest.

Even if we eventually come to treat it entirely as an annual, this will not detract from its value, for it is a graceful flower and worthy of special care. Raising a batch of seedlings once a year is easily done. The seed may be sown at any time in spring and strong plants be ready to put out into their flowering quarters in autumn. The leaves of this species are quite distinct from those of *C. lanceolata*, being large, long, pinnate, and like those of the old *C. auriculata*. Its handsome flowers are borne on strong stems 12 inches to 18 inches in length, and the plate by no means exaggerates their size. In the garden the flowers are brilliant and long-lasting, and they are also valuable for cutting.

A. H.

THE WEEK'S WORK.

KITCHEN GARDEN.

SELECTING SEEDS.—The season is at hand for selecting the various kinds of seeds necessary for the coming season, and the earlier they are secured the better the quality, while there is less fear of any kind being sold out. It is none too early to commence sowing, so that there is no gain in leaving this work. Such things as early Radishes, Peas and Potatoes will need attention, and there is more leisure now than when the season is more advanced. In the selection of novelties much depends upon the means to grow them and the purpose for which they are required when grown. If cost is a consideration, one must grow old things that can be relied upon.

GREEN VEGETABLES.—Owing to the absence of frost there is no lack of green vegetables of every kind. Such things as Coleworts and Cabbage planted for autumn use have, so far, never received a check. With such mild weather it will be wise to save all forcing roots as much as possible, as in the early spring the green crops will run so quickly that there will then be a greater difficulty in providing a varied supply than at any other season. Cauliflowers and Broccoli, so far, have done well, and though later kinds will get damaged should severe frosts follow, so far these have been more plentiful than usual. The early varieties of winter Broccoli are much earlier than usual. I have February varieties showing at this date. These may be retarded by lifting, planting closely together and protecting in severe weather. The Kales should be reserved for later supplies, as these will stand sharp weather if hardly grown. A good breadth of late Seakale will be invaluable in May if reserved for that purpose. The crowns will only need covering with fine ashes, banking up soil later to blanch the

growths. If leaf mould or litter is plentiful it may be used as a top covering.

MUSHROOMS.—These should now be plentiful if previous calendar notes have been carried out. With a high outside temperature everything has favoured the growth of Mushrooms, as the required temperature will have been maintained without recourse to fire heat. I have always found the best flavoured Mushrooms are secured in cool or what may be termed low temperatures. A nice growing temperature of 55° is most suitable, and though there is no harm in 5° either way, the one given is a safe one, and in severe weather 5° less would be perfectly safe. Old beds will need assistance in the way of food and watering if dry. When necessary to soak the beds apply water in a tepid state, or, what is better, use liquid manure in a warm state. After watering, cover the surface of the beds with short, dry litter to maintain an even temperature. Beds that have become poor may be improved by placing mats over the surface, supported on strips of wood, laying a light covering of warm litter on the mats for a time till new growth is made. In underground houses in cold weather a small quantity of fresh stable manure placed in a heap in the house will do good.

SUCCESSIONAL BEDS will need more attention, as at this season there is more difficulty in getting the manure in a suitable state. To prevent overheating it is advisable to dry in small quantities, or in buildings where rain or frost cannot spoil the manure. I have often used the material in a rougher state than is usually advised should there be any scarcity of material, as it is not wise to allow the manure to get so dry that it does not heat thoroughly all through the whole mass when made up. Firm beds are essential to get good succulent growths, and a fair thickness of good maiden stiff loam thoroughly beaten tends to a fleshy growth. Those who have neither houses nor underground cellars may often get a good return by making beds in any old building. Such places must be free from drip, and in severe weather the beds need extra covering to prevent cold checking the growth. Good results are obtained from beds under dry stages. In large boxes I have often seen fine crops.

EARLY TOMATOES.—Now is a good time to sow a small quantity of Tomato seed. Tomatoes may now be grown by those with only limited means as regards space. I prefer to sow the early lot in very small pots, a few seeds in each, and when above ground to thin to the strongest. Sow in a warm house, and if a little bottom-heat is at command, so much the better. Sow an early kind, such as *Prelude*, *Conference* or *Conqueror*; failing bottom-heat, place on a warm sunny shelf and from the start grow near the light. By sowing seed thickly in pans or pots and pricking off afterwards much time is lost. The seedlings being very tender are some time in getting over the potting off. A suitable temperature for the plants when in the rough leaf is 60° to 65° by day with a free circulation of air as the plants strengthen, and 10° lower by night. When repotting use sound loam made firm, but avoid manure, which is best given in a liquid form when the plants are fruiting. Some advise manure to make a strong plant, but it tends to long-jointed wood and the fruits come only at the top of the plant instead of a few inches from the pot. Those who raise from cuttings for early fruit should now give a shift if the plants have been wintered in small pots. Here a different mode of culture is necessary, as the cuttings are never too strong and require some food to create new wood. A little bone-meal mixed with the soil is beneficial, and a close house for a short time after repotting.

FRUITING PLANTS.—Plants sown some months ago have grown so vigorously during the winter, that repotting was necessary earlier than usual. The earliest plants now in their fruiting pots, 8 inches or 10 inches as advised, are now in condition to be tied up to the rafters and got in position for fruiting. Given good treatment, these plants should fruit freely in March and give the supply till the plants sown at this date come in. I have

\* Drawn for THE GARDEN by H. G. Moon at Gravetye Manor. Lithographed and printed by Guillaume Severeys.

secured the best results by growing in low pits, the plants being trained to the roof, as they fruit sooner when they get all the light possible. By plunging the pots in good soil over the rims the plants get a new supply of food just as the fruits are formed and take less water than when grown with the roots more exposed.

**PLANTS IN FRAMES.**—Various plants are housed in cold frames, and they often suffer more at this season from damp than cold. Cauliflowers in pots or planted out should not be allowed to get attacked by mildew. Dry wood ashes is a valuable fertiliser and preventive of disease. Plants at all infested should get a dressing of fine sulphur and protection from heavy rains for a time. It is also a good plan to firm the soil if at all loose in the pots when going over the plants. Worms are harmful, and should be destroyed by watering with lime water or clear soot water. The plants at this date should be freely exposed in fine weather to prevent drawing. Lettuces in frames for spring use need similar attention to prevent decay. There should be no delay in covering with frames. Endive required for the next month's supply, as the blanched hearts are so soon injured by frost after a spell of mild weather. Peas sown in pots for planting out should be freely exposed in fine weather and only sparingly supplied with water.

G. WYTHES.

### FRUIT HOUSES.

**EARLY PERMANENT VINERY.**—With mild, almost frost-free weather, old Vines which have been forced for many years have broke exceptionally early this season, few blanks or irregularities being visible. With lengthening days and probable glimpses of warm sunshine, night figures which have up till now ranged from 50 to 52° may with advantage be raised to 55°, this being maintained even when the nights are frosty, as the tender leafage—being in somewhat close proximity to the roof glass—is easily injuriously affected should the mercury fall to any appreciable extent between midnight and daybreak. The chief use of the syringe being to induce the eyes to leave their sheath, no advantage, but rather the reverse, follows its frequent use after this stage is reached. A slight morning spray may occasionally be administered when sun heat raises the thermometer from 7 to 8, a chink of air being given in sheltered houses when 70° is reached, this being withdrawn at 1 p.m., sprinkled walls, floors and borders alone supplying the moisture for the night. As soon as growth is an inch long, liquid manure diluted to one-fourth its strength may be regularly poured into the evaporating pans, the same precaution being necessary in regard to hot steam arising from neglect in keeping the pans filled, as in the case of pot Vines. Dry corners must receive an extra charge from the syringe or fine-rosed watering pot, or these spots neglected will quickly encourage a colony of spider or thrips, which may prove a source of annoyance the whole forcing season through. In the cases of Vines whose roots were lifted in autumn, and consequently lie near the surface, I would advise that the daily moistening of the surface of the border be supplied by the syringe rather than by the watering pot, as saturation prior to the formation of numerous fresh rootlets may result in wholesale decay. Where a rod of Muscat of Alexandria or Madresfield Court occupies one end of the house, the ventilators, if not on the continuous system, may well be left closed at that particular point, these varieties, of course, requiring extra heat, particularly in the early stages of growth. In the majority of cases the crop of Lady Downe's may now be cut and bottled, the berries after this date keeping more satisfactorily in the fruit room than on the Vines. As these Vines are not as a rule started until March, and then very gradually, root-lifting—where this is found needful, and additional soil for incorporating can be secured in a dryish state—may now be carried out. This remark, of course, applies to Vines rooting in an inside border. Touching the pruned wood

with styptic, thorough cleansing of glass, walls and woodwork, top-dressing where lifting is not necessary, together with a continual circulation of pure air, a few degrees of frost being rather beneficial than otherwise, must be the programme of the cultivator for the next two months and a half. Where the soil is light and the rainfall under average, wooden shutters which have been used to cover the borders may now be removed, at least for a time, the same being easily replaced should a long period of rain or snow intervene.

**LATE PEACH HOUSES.**—All preparatory work, more especially pruning of the trees in these structures, demands immediate attention, as the season, so far very mild and open, has induced expansion of bud in many varieties already, and the application of insecticides will soon be risky. Any blanks or faulty trees may still be made good from the open wall or nursery lines, as these, being subject to no undue forcing in spring, form fresh fibrous roots at the same ratio as the new growth. In planting keeping the roots well up towards the surface, adding abundance of rubble with the staple, with firm ramming, must be strictly observed, training, of course, being postponed until all fear of settling is past. Sea Eagle will be

should now be headed down. Where for various reasons orchard planting has not yet been done the work may yet be carried out with every prospect of good results, the winter thus far having proved so mild and free from heavy rains that the ground still retains a good percentage of the latent warmth of summer. Pruning also and thinning amongst Apples generally may now be proceeded with, avoiding a too free use of the saw amongst young trees especially, as our uncertain springs are best combated by a good amount of spray, this shielding the bloom and securing a set of fruit. The biennial system of turning up the surface of Grass laid orchards has much to recommend it, short rich stable manure spread over the upturned sods further enriching the soil, its virtue being washed down by winter and spring rains. Of course this does not apply to heavy soils, which are better treated to a broadcast sowing of some approved fertiliser in March or April.

JOHN CRAWFORD.

## CHRYSANTHEMUMS.

### JAPANESE CHRYSANTHEMUM VIVIAND MOREL.

Flowers of *Chrysanthemum Vivian Morel*.

OUT of all the many excellent varieties of exhibition Chrysanthemums, the palm must, I think, be unanimously awarded to Vivian Morel. It is what may be taken as a genuine type of the true Japanese Chrysanthemum, and the great favour with which it is regarded by growers and the frequency with which it is shown are sufficient evidence that its value is of no ordinary degree. Vivian Morel is a seedling from a rather noteworthy set. It was raised by M. Louis Lacroix, and sent out by him in the spring of 1890 with about a score of other novelties. The best of these, speaking, of course, from a purely English standpoint, are Vice-President Audiguier, Mlle. Marie Hoste, Sylphide, and Cléopâtre, all of which have attracted some attention here, although it has been reserved for their companion Vivian Morel to excite the keenest interest. At times we hear, and perhaps not without undue cause, of the exaggerated descriptions which are appended to the new French Chrysanthemums by their raisers. It seems to me, however, that those who are loudest in their condemnation do not make a proper allowance in this matter. These new French seedlings are grown and flowered in the open air, beneath a bright blue sky in the pure, clear atmosphere of Southern France. The French descriptions are consequently written from blooms obtained under such climatic influences, and when these plants are transferred to the neighbourhood of London, to be grown beneath our dull, smoky sky and flowered in a greenhouse, small wonder is it that the flowers belie the descriptions given to them by their raisers abroad. But whatever the case may be with other varieties, the charge does not hold good against the raiser of Vivian Morel, for the description by Lacroix was as simple and as fair as anyone could expect, and I give it translated word for word, viz.: "Vivian Morel (Lacr.).—True Japanese; blooms of the largest known, opens spirally, long petals of a fine soft rose, sometimes striped white; blooms in large clusters, very double, extra." The only part of this that seems to be immaterial is the blooms coming in clusters, a point of no interest to English growers, who do not allow their buds to come in that way at all, but to French growers who prefer quantity to quality, a matter no doubt of considerable moment. The catalogue being in French, is on the face of it scarcely intended to lead English purchasers astray.

found a good reliable Peach for late work and of good flavour.

**GOOSEBERRIES.**—In places at all liable to the attack of the dreaded caterpillar, lime and soot may be freely distributed around the stems and on the soil beneath the trees generally, to be afterwards forked in to a depth of 1 inch. This will have a tendency to destroy the grubs and eggs which may be located there. Cuttings of Gooseberries and Currants may still be inserted on any spare piece of ground, not necessarily exposed to the sun, although such a position is best. The ground should be in good heart and well firmed, the individual cuttings averaging in length from 9 inches to 1 foot. Some advocate removing all buds, save four or five at the summit; but this is unsafe, as sometimes sparrows or tomtits play havoc, leaving no buds to break into growth. The safest way is to allow every bud to remain intact until April; then to remove the stem ones, leaving four or more to form the head of the tree. Where the cuttings are inserted behind a north wall and the soil is at all inclined to be wet, mulching with dry litter or spent Mushroom manure will protect the base from severe frost.

**APPLES AND PEARS.**—Any trees intended for grafting should now have their branches shortened back to the proper length in order that the wounds may effectually callus over, and canker be thus avoided. Stocks also of Quinces and Pears

It was not until the autumn of 1891 that Vivian Morel was shown at the Aquarium in any numbers, although a first-class certificate was awarded to

Messrs. J. Laing & Sons in the autumn of 1890 for it, which award appears to have been repeated the following autumn, when the variety was staged by Mr. Owen. The R.H.S. also granted an award of merit to Messrs. Laing in 1890 for it, and, starting well, Vivand Morel has up to the present maintained the good opinion formed of it. It is not necessary to refer the reader to the audits which have been published showing the number of times Vivand Morel has been staged each year since its introduction, but it may be mentioned in passing that the first year after its introduction fourteen blooms were exhibited at the Aquarium show, while at the same place last November there were one hundred and seven. And this number does not include the classes for six blooms of one variety in which there were two stands of Vivand Morel, or twelve blooms more.

Whenever a good variety has made a name the growers are always keenly on the look out for a sport, and they had not long to wait in the case of the lower now under consideration. Mr. Davis, of Camberwell, was so fortunate as to secure a beautiful yellow sport, flushed with rosy-bronze, which he named Charles Davis, and which bids fair to be quite as great a favourite as the parent flower, for although it has only been in cultivation a year, it was shown eighty-nine times at the last November show at the Aquarium in the cut bloom classes, and twice in the class for six blooms of one variety.

One of the most curious facts, however, in connection with the sporting of Chrysanthemums has been remarked before, and it is that a variety, after being in cultivation for a time, will suddenly sport in several places far distant from one another and produce the same kind of flower. About a year ago Mr. W. Wells secured from Vivand Morel a pure green sport, which he has named Ethel Amnden, and I have since learned that my friend M. Fitzer, in the department of the Aisne, France, has had an identical experience. Although I have seen both of these green varieties, the French one seems to be the larger, and, I believe, will be distributed under the name of M. E. Tisserand. Whether they will prove to be the same when grown in the orthodox exhibition style is a question that time alone will prove.

C. HARMAN-PAYNE.

THE TECK FAMILY IN MIDWINTER.

It is now-a-days quite an easy matter to have a good supply of Chrysanthemums at Christmas and the new year. The varieties that lend themselves most easily to this form of culture and that are favoured by market growers belong to the Japanese and reflexed sections. At one time Princess Teck was rather largely grown for midwinter bloom, and then came its purer sport Lord Eversley, which had but a brief run of popularity. Just at that time such grand midwinter kinds as Golden Gem and Boule de Neige came into notice, and change of taste decreed that the high position held by the incurved kinds generally should be taken by the Japanese varieties. It must be admitted that the great bulk of Princess Teck blooms brought into Covent Garden were of indifferent quality. The plants were grown in the rough and ready way usually practised in market gardens, and the incurved varieties generally do not submit to this treatment so well as the Japanese and reflexed kinds.

A limited number of well-finished blooms of Princess Teck and its varieties still, however, finds its way into Covent Garden, and these, it is almost needless to say, are obtained from plants in pots. So far as I am aware, there are no other incurved varieties that lend themselves so well to this form of culture. One could scarcely desire anything better, for the Teck family gives us white, blush, yellow, bronze, and, including the old Hero of Stoke Newington, a shade of pink. I think that good blooms of Mrs. Davis and Lady Dorothy, cut with long stems and abundant healthy foliage, have a fine appearance in Christmas and new year decora-

tions. To get them at that season some judgment is required, for if the plants bloom too early the flowers are past their best when most valuable, and if retarding is carried too far the blooms will not incur, and one may just as well grow the reflexed varieties. It is necessary to time them so that the flowers are fully expanded by about December 10. If they have to finish off after that date they do not seem to be able to close up the centre, and generally present a rough appearance. Such at least is my experience. Early propagation is neither necessary nor desirable. The middle of February or, if the cuttings are strong, the beginning of March is quite soon enough. Grown along in the ordinary manner, they will be ready for 7-inch or 8-inch pots by the beginning of July. About the middle of June they should be stopped for the last time, and just at this time they need a little watching. I have found that the Teck varieties when stopped so late are apt to break badly, especially should the weather happen to be very hot and dry. The wood hardens, and some shoots will frequently refuse to break again. When they have been stopped a few days, it is well to give a couple of waterings with liquid manure, at the same time well syringing three times daily. This will give them a fillip, and will cause the young growths to push out more freely. At the same time watering must be conducted with some care, as topping checks root action. I have always made a point of not housing the plants till nearly or quite the middle of October. They may remain out a week longer if the weather is mild, for the longer they can be kept outside the more likely is the foliage to remain in good condition until the close of the year.

Owing to the late date at which the plants get their last shift, they do not need stimulants so much as those grown in the ordinary way, but they will require a certain amount of feeding. This should be continued in a greater or less degree through November, after which time only clear water should be used, as root activity is then on the decline. Plants intended for midwinter bloom ought to have more room when housed than the midseason ones. There should be a clear space between them, or many of the leaves will turn yellow, and it is impossible to get good incurved blooms at Christmas from plants that are in a great measure defoliated. They must, moreover, be near the glass and where they will get abundance of air when the weather is favourable. Very good blooms can be had in 6-inch pots, and this size is in many instances preferable, as small plants can generally be better accommodated through the winter than when grown in 8 inch pots.

J. C. B.

**Chrysanthemum Black Prince.**—I find there is already a Chrysanthemum named Black Prince in commerce, consequently I have changed the name of my variety from Black Prince to Owen's Brilliant. This is the variety to which the R.H.S. floral committee gave an award of merit on November 27 last.—R. OWEN.

**Chrysanthemum Golden Wedding.**—Is not over-feeding the cause of so many failures with this variety this season? I note "H." (p. 514) makes mention of this disaster of dying off being almost proverbial. My neighbour, Mr. Austin, of Witley Court, has been most successful with Golden Wedding this season, there not being any sudden dying off, which so many growers have been troubled with. The plants at Witley were decidedly under-fed, neither were they over-watered, being kept well on the dry side.—A. Y.

**Chrysanthemum Bouquet de Dame.**—In England this French-raised Japanese Chrysanthemum is rarely met with on an exhibition stand, but in Scotland it is shown frequently, and in such a condition that I could hardly have thought was possible. Such blooms as I saw in Edinburgh, Glasgow and Dundee I have never seen equalled in England. The Scotch-grown blooms were exceptionally deep, the florets broad and of the purest white.—E. M.

KITCHEN GARDEN.

THE MILD WEATHER AND VEGETABLES.

THE weather up to near the end of December has been remarkably mild, while the atmosphere, as usually happens in such cases, has been very moist and the rainfall comparatively light. This state of affairs has proved very favourable to planting and such like operations, and the coal or coke bill no one ought to grumble at, but, all the same, there is another side of the picture to be taken note of. As far as green winter vegetables are concerned, these have never been more plentiful nor, I think, better in quality, but so full of sap and vigour are most of them, that it only requires a moderately severe frost to cause an utter collapse. At the time these notes are being penned, so little like a change to severe frosts and cold weather generally presents itself, that it would appear useless to suggest preparing for wintry weather, yet there ought to be something done with Broccoli, Borecoles, Savoys, and Coleworts in the way of massing some of them together with a view to being able to quickly cover with mats or other protecting material. Should we not experience any very severe frosts, there will have been no labour wasted, as the very fact of lifting and laying in a quantity of the kind of vegetables named would serve to check their growth and be the means of providing a longer succession than would be the case if left alone and mild weather still continue; while if severe frosts do visit us, then there is a likelihood of the protected vegetables being the sole survivors. It is not growing vegetables only that are behaving different from what we wish them to do during the present winter, but some of those stored are being injuriously affected by the mildness of the weather. Onions were none too well matured last autumn when stored, and would probably have largely commenced growing afresh earlier than desirable in any case. As it happens, the mild weather has started them wholesale, especially where the precaution of roping or bunching them up and suspending in cool, airy quarters was not taken. In some instances storing in heaps in comparatively warm dark corners has already spoilt all that are left, a mass of shoots, roots, and decay taking the place of what should have been good sound bulbs for some time to come. Now, running short of Onions is a serious matter in most cases, and something ought to be done in the way of finding a substitute for sound Onions. Instead of throwing these apparently worthless Onions away, they ought all to be planted out on a border or quite in the open thickly in rows 1 foot apart. If they are only just starting, then keep them where they are and as cool as possible a month or six weeks longer, but if far advanced in growth, plant out all the more forward at once. A very severe frost would perhaps damage the young leaves, but they will stand more frost than will the dry roots, and should therefore be risked. The flower-heads should be pinched out directly they show, and eventually small roots thus treated will grow into larger ones, while the larger ones will divide into several, after the manner of Shallots, in each instance. Seeing that these Onions are wanted for early use, there would be no sense in leaving them to attain a fairly large size. Instead of this pull some as they are wanted for use, remove the outer or old skins, shorten the tops, divide those needing it, and there is then a serviceable bunch of young Onions, or Scallions, as sometimes termed, ready for use.

Where Onions are likely to be scarce, save as many Leeks and Shallots as possible, as these keep till quite late in the season, and are excellent for flavouring soups and such like.

Turnips are very plentiful and good in quality, but those stored are sprouting strongly, and the older roots left in the ground are beginning to run to seed. Both sprouting and forming greens or flower-growths have a most prejudicial effect upon the roots, rendering them of little value other than for flavouring. Both ought to be prevented as much as possible. A few minutes spent occasionally in turning a heap of roots and rubbing off the sprouts, if done in good time, would save them for several weeks longer, while if the roots in the ground are wanted for cooking, these, or a portion of them, should be pulled, topped, tailed and stored in a cool place or in a heap and strawed and soiled over. Late sowings have continued to make root-growth, and as yet there are no signs of these running prematurely to seed. All the same, I would advise storing a portion of them. Not till the supply is really exhausted do the more experienced gardeners realise what trouble they are likely to have with the cooks, Turnips being well-nigh regarded as indispensable. Much may be done towards forwarding a supply in frames on very mild hotbeds, but it is far less trouble to take good care of the old roots.

Should the present mild weather much longer continue, Celery will keep badly in many instances. Already I have seen several "sticks" showing, when cut open, that they are running to seed, and it will not be so very long before the hearts are practically worthless, always provided nothing is done to check this untoward occurrence. Sharp frosts or a spell of cold weather would do much towards checking bolting, though I do not advise waiting very long for this to come. It is not always the earliest sown that are the first to bolt, and it would be well, therefore, to test the plants in the various rows. Any fit for use and showing signs of running to seed should be first dug and good care taken of that still right at the heart. Lifting, tying strips of raffia round the stalks and replanting somewhat thickly and deeply in a fresh and, may be, cooler place are frequently practised later in the season; but the question is, would it not be better in many instances to take this precaution now, and thereby check heart growth? If laid in more closely, quite as much covered with soil as before, and, in addition, roughly covered with mats or dry straw litter whenever severe frosts are imminent, might be the means of saving a good supply from the destructive effects of frosts as well as retarding bolting.

Parsley is even more indispensable than either Turnips or Celery, and this season it has been hardened off so little, that the chances are frosts would destroy it wholesale. Nothing transplants more readily, and if a few deep boxes or pots were closely filled with strong plants, taking particular care of the principal root or underground stem, these could be placed in either pits, frames or houses and kept in reserve. Even if the outside supply does not fail, there is yet a likelihood of the early growth formed on the roots under cover proving very acceptable in April or May. Parsley can be forced as readily as Carrots, the seed being sown in frames on hotbeds in much the same manner; but once more let me advise my readers to preserve the old plants.

SELWOOD.

best. This is the way I have kept mine for many years, and that with the best results. In proof of this I have in my fruit room a good sized bulb that was ripened in September of 1893; consequently it has been out of the ground sixteen months, and now it has sprouted 2 inches long. This bulb was strung with others in ropes and hung close to the roof of our potting shed all through last winter, and only removed after Midsummer Day into the fruit room. By keeping in this way I generally have good sound bulbs till the end of June. Mr. Temple, when at Impney Hall, used to keep his Onions in this way. Undoubtedly many of the old kinds are far better keepers than some of the new kinds. J. CROOK.

**Hardiness of Onions.**—Like "J. R.'s" (p. 479), my mode of storing Onions is the reverse of "W. G. C.'s," as given at pages 408 and 409. I have never stored mine in a close room or building of any kind, and in my opinion the more airy, cool and exposed the place that can be given the better. The bulk of my Onions, some forty or fifty bushels, are tied in bunches and hung to the rafters of a dry, airy shed, the bunches not touching each other, but fairly close, and they keep grandly. I have tried the plan advocated by "W. G. C." and failed. I think the more the bulbs are exposed in a dry place, free of straw or other covering, the better. I do not like the plan of laying Onions on the floor or even on racks, except when drying after lifting. I have found them decay and grow out badly.—S. G. J.

#### SEAKALE CULTURE.

It is a significant fact that while the majority of vegetables suffered more or less from the great heat and absence of moisture in 1893, Seakale seemed to be suited to a degree. Growth, whether in permanent beds or in those planted with root thongs in the spring, was both early and vigorous, resulting in well-formed and prominent crowns, from which the foliage parted in October in a perfectly yellow and ripe condition. These roots, when lifted and placed in heat, responded readily, producing good supplies of stout Kale in a minimum of time. Last season, however, though the cuttings were much stronger than usual and well sprouted at the foot of a south wall previous to planting, growth was not nearly so satisfactory, proof that, however good the general cultural treatment may be, sun, and plenty of it, is indispensable to secure the best results. Seakale is an important winter dish in all first-class establishments, yet how often do we find it growing in about the worst possible positions, perhaps associated with Rhubarb and Jerusalem Artichokes in some out-of-the-way corner, shaded by high walls or trees, and in wet, heavily manured soil. Under these conditions, by no means good, though prolonged, growth ensues, the leaves often continuing in a green state well into November, finally being smitten by frost and rotting instead of ripening. That Seakale does not require such rich ground as is generally supposed is proved by old permanent beds which have been forced for ten or twelve years by the old-fashioned method of pots and leaves. These from the time they were planted have received no stimulant, save perhaps a little ordinary manure which has been pricked into the surface in spring, yet their vigour and productiveness are maintained. For the accommodation of first early batches a south border is to be preferred, although where ground is scarce such a site cannot always be spared. If the ground is in pretty good heart the Seakale may follow some other ordinary crop without any further preparation save digging and making firm. As each batch of crowns is lifted for forcing, all the stout rootlets should be cut into lengths of

some 4 inches of 5 inches, and the top from which growth is expected made quite smooth with a sharp knife. They should then be dibbled into boxes or frames of light sandy soil, and the cut portion covered with silver or river sand to induce a speedy callus. Failing these receptacles, the foot of a south wall will answer well, light leafy soil being used for imbedding. If the early part of the year is very mild the cuttings must be watched, as sometimes the new succulent growths will push through the soil and fall a prey to frost. A little covering of soil will avert this. When making the cuttings is postponed till planting time a whole month is lost, and crowns suitable for early forcing cannot be expected. As a rule the first week in April is a good time for planting, at which time the tender growths should be reduced to four or five on each cutting. A space of 2½ feet between the rows and 18 inches between each plant is not too much, each cutting being lowered, just beneath the ground level and slightly wounded over with soil to shield from frost. When 6 inches of growth have been made, the leads must be further reduced to two or at the most three to each stool, these being as many as can be properly exposed to sun, light, and air. Where the earliest batch occupies a south sunny border, should the summer prove hot and dry, a slight mulch of spent Mushroom manure may be given, and one or two waterings with liquid manure. Towards the end of October it is a good plan to force a spade down on either side of the stools to sever some of the strongest roots, and thus hasten ripening and rest. In regard to flavour in Seakale, I am of opinion that none equals that grown under pots and leaves, the moist vegetable ammonia given out by them seeming to impart a special sweetness. When forced indoors the roots should not be placed too near very hot pipes or in dry corners, as under such conditions growth is invariably not only spindly but watery and insipid. Several growers for market in the neighbourhood of Bristol allow plenty of room between the rows and stools and lift every other row to force. In spring the crowns in the remaining rows are covered with flower-pots, the latter being finally banked up with the soil from the intervening spaces. Thus a late supply of good white Kale is secured. When cinder ashes or leaf soil is used for mounding up in spring, the crowns are very apt to push through the compost, becoming not only green and insipid, but unsightly when placed on the table.

J. CRAWFORD.

#### COLOUR IN BEETROOT.

THE roots of Beetroot with a dull crimson or nearly black colour are, I think, inferior in quality to the lighter coloured roots. I am aware colour does not always denote high quality, as some of the Egyptian or Turnip-rooted Beets are of a pale colour, but nevertheless of good quality when quickly grown. I recently asked a large grower as to the demand for light-coloured roots, his answer being that the few who understood good quality in vegetables always selected small or medium-sized roots in preference to large ones, and that he always was careful to supply those with bright red flesh, as these were less earthy in taste and always realised a good price. The flavour of Beetroot this season is different from that of last year. This is readily accounted for, as the soil being much warmer in 1893 growth was more rapid; whereas last year it has been slow and there has been much moisture. It may be said that early sowing has much to do with flavour. This I admit, and I do not prac-

**Notes on Onions.**—Notwithstanding all that has been written in THE GARDEN as to the keeping of Onions, I find that when bunched and hung up under the roof of cold airy sheds they keep

tise it for late roots, sowing the Turnip-rooted kinds for summer use. I am also aware soils full of manure do not add to flavour. Last season I secured three crops of Turnip-rooted kinds, sowing in March, June, and early in August, and the last roots were equally as good as the first and grew very quickly. This season later sowings failed completely. It may be said, why sow Turnip-rooted kinds late when good roots of the long section may be secured with far less trouble? The answer is that there is a great demand for the Turnip-rooted forms when about the size of a cricket ball, or even smaller, for salad, and I believe a much better flavour is secured from quickly grown roots. I grow the Turnip-rooted Beet on account of its quick growth and good quality. Cooking is also important. Among the larger red or light crimson kinds of good quality are Covent Garden Red and Cheltenham Green Top, one of the best flavoured sorts I have grown if sown late and in poor soil. Osborn's Select Red, Nutting's Red, a medium-sized root of splendid quality, and Pragnell's Exhibition are also good. There are others worth a place, but from a selection of some twenty varieties I have found those named above best as regards quality. W. S. M.

SHORT NOTES.—KITCHEN.

**Potato Windsor Castle.**—I have found this one of the very best varieties. Those who value quality in Potatoes would do well to give it a trial. Not only is there an absence of small tubers, but a great weight is secured from a limited space if the plants are not crowded. It may be described as a dwarf Magnum Bonum, and, like that well-known variety, is not liable to be attacked by disease. In thin or gravelly soils it may be planted closer than the Magnum and will yield a fair crop, but, given good land, crowding should be avoided.—G. W.

**Walcheren Cauliflower or Broccoli.**—Many years ago this variety was largely grown in the north, and if sown in April, May, June and July, good heads will be secured from June to December. I find this as hardy as the early Broccoli. For many years I have sown it in August from the 10th to the 20th for spring cutting. I do not know of any variety more reliable for standing the winter, and though it may be a few days later than some of the smaller growing Cauliflowers, it is more valuable on account of its hardiness and freedom from running or opening in warm weather.—S. H. B.

ORCHIDS.

PLATYCLINIS.

This small genus of epiphytal Orchids was formerly known in our gardens as *Dendrochilum*, and even at the present day this name is very frequently used. There are upwards of a dozen species known, these being distributed over India and the Malay Archipelago. Very few, however, are sufficiently beautiful to find favour with the majority of Orchid growers. Those generally cultivated are the species mentioned below, and all are found in the Philippine Islands. They flower at different seasons of the year, are very interesting when in bloom, and as they occupy but little space, they should find a place in every collection. These plants being natives of a very hot climate naturally require strong heat to grow them successfully under cultivation, and should be placed in the East India house or at the warmest end of the Cattleya house. Whilst making their growth they enjoy a liberal supply of water at the roots. During the resting season the plants should be kept dry, only enough water being given to keep the soil moist. The most suitable time to repot *Platyclinis* is

shortly after the flowers are past, and the compost should consist of chopped fibrous peat and Sphagnum Moss, the pots being quite half filled with good drainage.

**P. COBBIANA.**—This interesting species, introduced by Messrs. Low & Co., of Clapton, about 1880, usually blooms during the autumn months. It produces elongated, conical-shaped bulbs, each about 2 inches high, with lanceolate leaves three times as long. The flowers, light sulphur-yellow, with an orange lip, are borne densely upon a drooping raceme about 1 foot in length. These are somewhat similar to those of *P. glumacea*, but the plant is quite distinct in the formation of the bulbs, and, moreover, blooms at quite a different season. It first flowered in the collection of Mr. Walter Cobb. At the present time this species will just be commencing to start into growth.

**P. FILIFORMIS,** a much better-known species than the preceding, was first seen in flower in this country over fifty years ago, having been discovered by Cummings two or three years previously and sent to the Messrs. Loddiges, of Hackney. This kind grows to about 6 inches in height, and produces a filiform pendulous raceme of about 15 inches in length during the months of June, July and August. These racemes often bear fifty to sixty individual blooms, sometimes more, these being of a greenish canary-yellow and very small. The drooping spikes, which are freely produced, make it a very attractive plant. During the winter months this species should be quite at rest.

**P. GLUMACEA.**—This species will now be in active growth, and should be given plenty of water, as it will produce its elegant racemes during the spring months. The flowers, whitish yellow, are borne upon the apical half of the spike only, and have a pleasing fragrance. The pseudo-bulbs are ovoid and sheathed with brownish scales; the leaves attain 12 inches or more in length. This is one of the most desirable kinds, and a great favourite with Orchid lovers. It was introduced just forty-five years ago.

**P. UNGATA.**—A spike of this pretty kind is to hand from "T. W. O." for a name. The present season is its usual flowering time, and the spike received measures 9 inches in length; the blooms are large for this genus and of a greenish white, somewhat resembling those of *P. filiformis*. It is a very desirable plant, imported for the first time by Messrs. Low, of Clapton.

WM. HUGH GOWER.

**Twin-flowered Cypripediums.**—Twin-flowered *Cypripediums* appear to be unusually prevalent this season. On two of my largest specimens of *Cypripedium insigne* the flowers are showing in a similar way to that described by Mr. Wood. On looking at a plant of *C. barbatum*, I also observe a twin flower-spike. *C. bellatulum* a few weeks back was also the same, but the greatest number are showing on *C. Spicerianum*. Four of the largest plants of *C. Spicerianum* have every spike twin-flowered. It appears strange that only a few plants of this variety should show this tendency. This makes me think it is more a seminal variety than due to vigorous growth. I take this view because the largest and most vigorous plant is only single-flowered.—A. YOUNG.

**Cypripedium insigne of the Sarderæ section.**—Since the introduction of this most distinct and valuable variety by Mr. Sander, of St. Albans, many plants which have laid claim to rivaling *C. insigne Sanderæ* have flowered, but none, with the exception of *C. insigne Ernestianum*, have equalled it in colour. The flowers of *C. i. Ernestianum* differ in shape from those of *C. i. Sanderæ*, being more like those of a good *C. i. Chantioi* and of a clear apple-green, with a white margin to the dorsal sepal, which bears faint traces of spots where these are usually seen in the typical form. It is a very beautiful and distinct variety and makes a fine companion to Mr. Sander's form. These and others of this section have appeared from the *montanum* type, of which there have been enormous quantities

imported during recent years, and amongst them the following kinds have from time to time turned up, but although very fine and distinct, are, nevertheless, quite different from the two above-mentioned plants: *C. i. Macfarlanianum*, a variety with somewhat narrow segments; *C. i. Sanderianum*, a very clear flower, the spotting almost entirely absent; *C. i. Youngianum*, a very pretty kind and very similar to one recently named *C. i. Lutwyehianum*; and *C. i. Eyermannianum*, a variety of American origin and very distinct. These of themselves form a very pretty and interesting group.—W. H. G.

**Flowers from Pitlochry, Scotland.**—From Mr. W. Macdonald, Atholl, Pitlochry, comes a box of flowers, amongst which is a very curious malformed bloom of *Cattleya labiata* having seven segments, but with no proper lip, the two lateral sepals being the only parts of true character. The dorsal sepal and other four parts are all of the same shape and markings as are usually seen in the lip of an ordinary form—rich crimson, heavily suffused with orange at the base, and nicely fringed at the margin. Although very curious it is less beautiful than an ordinary bloom. The *Cypripedium* of the *insigne* cross was far too much damaged to say what it might be, but the dorsal sepals appear to have some fine purple spots. It may probably have been the result of hybridising a good form of *C. insigne* with *C. villosum* or *C. venustum*. A fine flower of *C. Boxalli* with richly coloured petals was also included.—W.

STOVE AND GREENHOUSE.

PELARGONIUMS DURING WINTER.

To be successful with these plants at their flowering time, they must not be neglected in the sunless period of the year, and important items of culture should receive proper attention now. In the case of the large-flowered or show and regal kinds, for example, we are apt to keep them too warm, and the growth becomes spindly, and perhaps attacked with aphides. Should the latter occur, lose no time in cleansing the plants by fumigating.

The temperature for all *Pelargoniums* should not go much above 50°. We want them to be steadily growing, that is all, and the pipes just warm enough to dispel damp. Of course this does not refer to plants of the zonal class which may have been specially prepared for winter blooming. Those of the show and regal type may be shifted into the flowering pots, and the principal things to consider are the sizes of the pots and the manner of doing the work. One thing noticeable about the plants we see in the markets is the small pots employed; and as I am not far wrong in saying that *Pelargoniums* are not generally well done in private gardens, the use of large pots in such places is a common error. Specimen plants may be grown in an 8-inch pot; a size or two less, therefore, is amply sufficient for ordinary use.

One need not be particular as to soil. I use with excellent results the old compost that has done duty in growing the *Chrysanthemums*. If this is saved when the plants are turned out and kept in a dry place, it provides a soil good enough for *Pelargoniums*, and where there is some trouble as well as expense in obtaining a supply of turf is economical. The old compost is merely sifted and a sprinkling of bone-dust added, then it is ready for use. Pot firmly. This is one of the secrets of successful cultivation. Ram the soil into the pots with a heavy stick, and the growth resulting from such treatment will be sturdy and short-jointed. A handful of half-inch bones at the bottom of each pot over the crocks is most beneficial. All classes of *Pelargoniums* are assisted by these; the roots

ramble among them and a healthy tone to the foliage is apparent when bones are employed. After the potting is done, give the plants a good soaking of water. This will last some time, for the aim must be to keep the roots on the dry side. See, however, that this does not reach the flagging point, for valuable plants are thereby often lost. They get too dry, and we at once give them a soaking. The roots may be already partly killed by being parched, as it were, and the water but adds to the damage done in at once soddening the earth. In this case it is always best to first damp the foliage as well as the surface of the soil slightly for a few days, and brighten the plant up before water at the roots is given.

Air in abundance should be given in favourable weather, and only just enough fire-heat to command the temperature mentioned. Unless the plants have become drawn up weakly, no stopping is required. Handsome bushes are best obtained if they are kept sturdy and allowed to break side shoots naturally. These should be tied out when young, so that room is made for others that will follow and space for their development given. If there be a superabundance of side growths, a little thinning out may be done. These young shoots, if put singly into small pots and placed on a shelf near the glass of a warm greenhouse, strike readily, and provide young stock in the event of the older plants losing health or being worn out by age.

Zonal Pelargoniums require similar treatment to that noted in the matter of water, and the leaves must be kept free from moisture at this time of the year. Where old plants which flowered in early autumn are past and have become leggy, a little trimming up should be done. If the shoots are cut back half their length there is little danger of decay, but when cut back quite close at this time of the year, we run a risk of killing the plants entirely. The tops may be used for providing young plants, and these should have the benefit of a warmer house than the parent plants are growing in. When rooted give the young plants a shift into 5-inch pots, and thus nice, fresh-looking specimens of a useful size for furnishing rooms and so on are obtained early in the season. The older plants need some attention at the roots as soon as fresh growth takes place. They may be turned out of their pots, a good portion of the old soil taken away, and returned to others very little larger than they before occupied. The fresh compost will give new vigour, as it has already been pointed out what a mistake the use of large pots is. There is also another class of the Pelargonium, namely, the Ivy-leaf section, in which the use of small pots is particularly necessary to successful flowering. These are of a very rampant nature, and the only means of getting a good quantity of flower trusses is by restricting the root-run. Varieties of this class, again, require timely topping, and they ought not to be allowed to form many joints at this time of the year before the tip of each shoot is taken out.

All Pelargonium plants should have ample room and be stood near the glass to benefit by light and air. They respond to feeding with stimulants when the flower buds show, in bearing fine trusses of bloom. Manures containing ammonia, such as soot and guano, are especially suitable. As the days lengthen, water in abundance will be needed, and keeping the plants on what is called the dry side no longer applicable. There is the opposite danger in not giving enough when the plants are growing in the small pots insisted upon. H. S. L.

#### RICHARDIA ALBO-MACULATA.

I do not quite agree with "W. W.'s" statement that this is only of botanical interest. I have grown it for some years, and find that, from a decorative point of view, it has considerable value. The flowers, it is true, are, as compared with those of *R. æthiopia*, insignificant; but a good-sized specimen with well-developed foliage is decidedly effective, and, being comparatively hardy, can be used where *Caladiums* and other tender variegated-leaved things are inadmissible. Unlike the Nile Lily, it goes to rest in the winter, and this is probably the main cause of its not being very much grown. For summer decoration in the open air it is, however, held in some esteem, being very much more weather-proof than many of the fine-leaved things commonly used. The tubers are very tenacious of life; they can be taken up in autumn, stored away dry and not one in a hundred will die. If left in the ground only a very hard winter will injure them. I have had them come through 20° of frost unharmed, and a cold, damp winter does not seem to appreciably affect them. I have no doubt that a moderate covering of some light material would ensure their safety in all but very heavy soils in low-lying situations. In such a high degree are the tubers possessed of enduring power, that I have kept some nearly two years out of the soil, and then they sprouted. I once had about a bushel of imported roots, and what they went through before they came into my hands would have killed most tuberous or bulbous-rooted things outright. This ability to retain vitality through a long resting period may be taken advantage of in a certain way. By keeping the tubers quite dry until August and then potting them the season of growth is reversed. They come into full leaf by the close of the autumn, and remain in good order all through the winter if given a temperature of about 50°. They can then be employed for any of the purposes for which such things are in request, and will remain in good form in a heated apartment all through the winter months.

J. C. B.

**Roman Hyacinths.**—The past season may now, we can reasonably assume, have been the best possible for the essential (or supposed) ripening of bulbous plants. Note the words in brackets, for I think it is possible that too much reliance is placed upon thorough ripening. Be this as it may, the one thing very evident in my case is the very satisfactory way in which Roman Hyacinths are flowering this year. I force them for cutting by the thousand for a private supply, and never remember to have had them so good in any previous season, the succession spikes being much finer than usual and in greater quantities also.—GROWER.

**Rogiera gratissima.**—Dwellers in the immediate neighbourhood of London can seldom enjoy the beauty of this Mexican shrub, as it is so susceptible to the fogs experienced during the winter months, that a few hours' exposure thereto will suffice to scorch all the leaves as if they had been burnt. It is certainly very beautiful when in a thriving condition, the dark green leaves being lit up by clusters of flowers somewhat in the way of the *Laurustinus*, but of a pleasing shade of soft pink. Like the *Luculia*, this will, as a rule, succeed better when planted out than in pots, and it needs a free circulation of air whenever possible. When in a thriving state not only do the individual flowers remain fresh for a good while, but a succession of bloom is also kept up for some time. This plant is now included in the genus *Rondeletia*, but it is far better known under the generic name of *Rogiera*.—T.

**Canarina Campanula.**—This is a decidedly interesting and at the same time pretty flowering plant, that produces its blossoms towards the end of the year. It is said to have been introduced into this country from the Canary Islands in 1696, but it is now very seldom seen, and may in vain be sought for in most nurseries. This *Canarina* forms a fleshy root-stock, from whence spring

stout succulent shoots that reach a height of a yard or two. These shoots branch out towards the upper part, and are there plentifully clothed with foliage. The flowers, which are there freely borne, are bell-shaped, drooping, and about the size of those of the garden varieties of *Abutilon*, to which they bear a considerable resemblance. In colour they are generally a sort of yellowish red, with deeper veins. This *Canarina* behaves in a very different manner from most of the occupants of our greenhouses, as it continues fresh and green for some time after flowering; then just as the majority of plants are in full growth this goes to rest, and continues in that state till early autumn, when it pushes up the stout shoots and grows quickly. During the season of rest it should be kept fairly dry, then, just as it is on the point of starting, it should be to a great extent shaken clear of the old soil and repotted. A rather light compost suits it best, and thorough drainage must be ensured. This last remark especially applies if it is planted out in the greenhouse, under which conditions it does well.—H. P.

**Rubus rosæfolius plenus.**—Some fifteen or sixteen years ago a considerable amount of attention was directed towards this Bramble as a very desirable subject for flowering in a warm greenhouse during the dull days of winter; indeed, it was then so much in demand that considerable numbers of it were to be seen in many nurseries. Now, however, it is rarely met with, though it is certainly very pretty and deserves more recognition than is accorded it now-a-days. It is not one of the rambling growing species of Bramble, but forms an erect bushy plant, that pushes up suckers freely, and soon forms a dense mass. The stems are thickly studded with hooked spines, while the Rose-like leaves are of a pale green tint and thin in texture. The flowers, which are borne in loose corymbs, are pure white and double. A few good healthy plants will keep up a show of bloom for some time, and that, too, when flowers are scarce. Another name for it is *Rubus rosæfolius coronarius*. It is easily grown. Cuttings strike root readily during the spring months if treated as other soft-wooded subjects.—H. P.

**Libonia penrhosiensis** is certainly one of the best winter-blooming plants we have, and when well grown is very effective at this season. It requires good culture however, and, like its congener *floribunda*, has a miserable appearance if in any way neglected during the growing season. In order to get well-budded specimens it is necessary to give the plants a long season of growth. Cuttings struck early in March will grow into good plants by the autumn if given high culture, but I have noted that the best results are obtained when one can start in the spring with young plants that have never had artificial warmth. *Libonias* may be easily propagated from cuttings put in during early summer when the wood is succulent, and these will come into small pots in which they are to remain till spring. If these are shifted into 4½-inch pots about the middle of March and then put into 6-inch ones later on they will make fine little specimens by autumn. *Libonias* require a considerable amount of sun and air, and when in full growth plenty of water.—J. C. B.

**Ipomæas.**—As a winter-flowering climber for the stove *Ipomæa Horsfalliae* is a distinctly ornamental species with very showy flowers produced in large trusses, which continue for a long time to produce the blooms, only two or three being expanded at once. The colour is particularly rich, quite different from anything in its season, a deep satiny rose. Although its flowers, like those of all of the *Convolvulaceæ*, are very fugitive, yet the succession in which they are produced makes full amends for this. A good mode of training it is up columns or rafters. It needs a fairly large pot to accommodate its large fleshy roots, but does not then require frequent shifts. It will thrive well in an ordinary stove temperature, whereas *Ipomæa Leari*, which has deep brilliant blue flowers, requires a moister atmosphere, otherwise it is very liable to red spider. This latter variety is much more rapid in growth, flowering

earlier, also being usually at its best during August and September. Preferably I would grow *I. Leari* in an aquatic house, upon the roof of which it would simply revel. *Ipomœa Quamoclit* is an annual stove species which, I should gather, is extremely handsome in its native habitat, from which I have had seeds of it sent as well as from India. It is of very light and elegant growth, but under cultivation does not, unless very favourably circumstanced, flower so freely as one could wish. From imported seeds I have had dark red, yellow and white varieties. It only needs small pots, a good means of support being small sprays of Birch. *Ipomœa rubro-cœrulea* does not appear to be grown so much as it deserves, owing probably to its blooming during the summer, when the flowers would not last many hours in perfection. For it there cannot be a great call, if trade plant catalogues are to be taken as any criterion, for in two well-known ones it is not included.—GROWER.

**Echeveria retusa.**—It is somewhat a matter for surprise that this very easily grown and free-flowering winter plant is not met with in larger quantities in private gardens, where it would be very useful. The market growers are waking up to its merits, and some of them grow it largely. It will flower about now without any difficulty in a light dry greenhouse, a shelf near the glass being a good position for it. Its propagation is of the easiest, the young plants being kept in the full sunshine out of doors all the summer. Only a 6-inch pot is required to produce a good useful plant.—GROWER.

DAFFODILS FOR FORCING AND POT CULTURE.

No time should now be lost in introducing these as required into warmth for forcing. Properly planted in due time in September and October and given sound healthy bulbs, they will now be well rooted and ready to flower when under glass. Those put in to form the first early batches are coming away nicely, but in these, as in all else that is forced exceptionally early, size of flower and often colour, too, are wanting. Length of stem is invariably wanting, no matter what the quality of the bulbs or the treatment accorded, so that it is no gain in private gardens generally for the sake of a few days in their flowering to destroy, or at least diminish, the length of flowering stem in these exceedingly useful and much-admired flowers of spring. Planted early and deeply covered with ashes or cocoa-nut fibre and given a long season in the open to form roots and commence their growth, success is in the main ensured—indeed, the flower-buds will be almost in sight as soon as the bulbs are taken from the plunging material, while the growth will be from 2 inches to 3 inches high and the bulbs a mass of roots. Where required only for producing blooms, pots 7 inches or 8 inches across are very useful for the purpose. When first removed from the plunging bed it will be best if the entire batch be transferred to a frame or pit from which frost is excluded at all times. The bulbs will also benefit if darkened with mats for a day or two and given a sufficient watering to carry all dirt fragments to the soil. If, of necessity, they must be taken to the greenhouse at once, take care the house during the first week is kept at about 45°, and if the weather is mild freely ventilated. Under these conditions all will be well. The dull weather and the humidity of the past few days are just suited to these plants at this time. Heat may be turned on slightly in about five or six days, limiting the maximum temperature to 55° by fire-heat. When growth has well begun take care the bulbs receive no check from insufficient water at the root, giving weak liquid manure every week till the flowers begin to colour. Syringe daily or twice daily if bright and generally maintain a moist atmosphere. The varieties best suited for earliest work are the Tenby Daffodil (*N. obvallaris*) and the common double yellow Daffodil (*N. Telamonius* pl.). Quickly following these come prin-

ceps, pallidus præcox, Golden Spur and Horsfieldi. *Poeticus ornatus*, however, must be named as indispensable, though at the same time somewhat fastidious when forced. This variety, more than all else, will not endure hard forcing, but by a gradual preparation and introduced by degrees into the temperatures named, this valuable variety may be brought well through the ordeal. Always place the pots, pans or boxes on a cool bottom. E. J.

**Bamboos as conservatory plants.**—As bearing out the views of "A. H." (p. 150) with regard to the value of Bamboos in the conservatory, I may mention that at Witley Court, in the large winter garden there, are several Bamboos growing in pots. On each side of the main entrance there are two very handsome specimens of *Arundinaria falcata*, each about 14 feet high.—A. Y.

**Jasminum grandiflorum.**—During the autumn, when the trade sales are being held, this variety of Jasmine is frequently met with as a dwarf plant, with an occasional truss or two of unexpanded blossoms. These are frequently propagated by grafting, which, I have an opinion, tends to make the growth more dwarf than it would otherwise be if cuttings or layers are the modes of propagation. Cuttings do not always strike freely, hence grafting comes in useful; but layers can be relied upon in course of time to make very useful plants. It is vigour that is wanted in this Jasmine, for it is as a climber that its usefulness is most manifest. Even then it is not one of the most rapid growers, but its progress, if a little slow, is just as sure. My mode of treatment has been to plant it out in good soil, peat and loam in about equal proportions being used. The plant in question was trained near the glass, so that the shoots had all the benefit of the light, no shading being in use where it was. Thus treated it grew quite strongly, making lateral shoots, thus adding to its free flowering—this being one of the terminal flowering species rather than a lateral one, as in *J. nudiflorum*. Flowering as it does during the late autumn and winter, it is extremely useful for cutting, making up well in either sprays or button-holes. Its fragrance is delicious, but not overpowering. It resembles most nearly *J. officinale*, but is quite distinct from that species. To grow it thoroughly well it should be planted out in a cool stove or temperate house; an ordinary greenhouse is scarcely warm enough for it to make a free growth. Pruning is rarely needed.—H. G.

**Jasminum gracillimum** is a worthy companion to *J. grandiflorum* and totally distinct from it, having hirsute foliage, as compared with the lustrous shining lark green of the other species. The species in question is a great advance upon *J. Sambac*, having flowers somewhat similar, but it is much more free in producing them. It should be grown in a warm or temperate house in order to encourage a free growth. I have kept it in a house that often falls to 40° during frost, but it did not thrive well. The best position for it, I find, is when trained as a rafter plant. In this way it is seen to the best possible advantage when in flower during the winter months. Its greatest enemy is the white scale, which seems extremely partial to it. What pruning is needful should be done after flowering.—H. G.

THE WINTER-FLOWERING JASMINE. (JASMINUM NUDIFLORUM.)

No variety of this beautiful race of plants is more in request perhaps than the species in question. It is a most popular plant, and that most deservedly so, being seen at its best on a warm wall with a southern or western aspect. In such a position it will flower earlier and oftentimes yield a wealth of blossom before the frosts are sufficiently severe to mar its beauty. For the covering of eastern or northern walls it may also be planted with safety, but on these aspects its earlier flowers are more liable to be caught. For the purpose of covering arches or gateways it is also very suitable. This Jasmine does not appear to be at all particular as

to soil; it must be poor indeed if good growth is not made. I have often been struck, if not actually amused, at the want of taste and lack of common sense in its management. Only just recently I saw an example that had been clipped as close (and correctly, I suppose) as if it were a Quick-set hedge. I hope the operator afterwards felt gratified by the results he had accomplished; no doubt the neat appearance was his satisfaction. Poor indeed, however, would this be to the pleasing effect of unpruned plants now in their full beauty. What possible pleasure there can be in this intolerant use of the shears I cannot possibly conceive. The growth even in itself of this Jasmine is very light and pretty, thus affording no excuse for mutilation whatever. After the flowering season is over then is the time to do any thinning out or pruning, a deal of the latter work being done in cutting the shoots when wreathed in blossom. Tie the growths in then so as to secure the plant for the next twelve months, but in the name of common sense do not afterwards attempt any more so-called work. When planted alone this variety leaves a bare appearance upon the walls during the winter unless the growths be very thick. To remedy this I would advise that it be planted or intermixed with *J. revolutum*, an evergreen species flowering during the summer, not so profuse perhaps as *J. officinale*, but none the less beautiful. *J. revolutum* and *J. nudiflorum* planted alternately and allowed to grow together would look well. In my own case I have a groundwork of a small-leaved Ivy close to the wall over which the shoots of *J. nudiflorum* are merely secured; this when in flower has also a very pretty effect. Amongst other climbers also it may be allowed to grow wild; its foliage being so very small, it can hardly do any harm. J. H.

WHAT'S IN A NAME?

Most of your readers will probably agree with "J. C. L.'s" somewhat cynical letter under the above heading, but none more strongly than I do, for this frequent change of names is a positive nuisance, which all amateurs must feel, for it is distinctly annoying to have to learn a new name for a friend of many years standing. I could quote very many examples, but will select only one, and that because in my case it had its humorous side. Many years ago one of your frequent correspondents, a great authority upon correct naming, kindly sent me a short note saying that he enclosed some seed of *Hyacinthus candicans*. When two or three years afterwards I told him how successful I had been in flowering *Hyacinthus candicans* from his seed, he seemed quite pained, remarking, "My dear sir, please never say that again; there is no such plant. I presume you mean *Galtonia candicans*." Naturally I was not loth to make the most of my opportunity.

There is, however, quite another aspect of the subject to which "J. C. L." does not allude, viz., the use by nurserymen of Latin names in their catalogues when English ones would certainly not tempt the average amateur. In this case the only possible answer to "What's in a name" is, I fear, "money."

As an example let me give the following extract from a well-known Dutch catalogue of this year's date: "*Cynara Scolymus*, purple, 1s. 6d. A noble plant, 3 feet to 6 feet high, growing well in a rich soil; flowers in early autumn. This is one of the most striking plants when seen isolated in the grass in the picturesque flower garden." Now this has appeared annually for many years, and in the days when I knew so very little that I used even to order plants from the description in catalogues, I bought a plant of *Cynara Scolymus*, only to find that there were two good rows of this "most striking plant" in my kitchen garden, and so for 1s. 6d. I learnt the Latin name of the Artichoke! Do you not remember how when there was rather a rage for Marguerites a smart nurseryman sent out *Chrysanthemum segetum*, describing it as a golden Marguerite and charging 2s. 6d. a packet

for the seed? I fancy he found a good deal of money in that name, and probably helped to get rid of one of the most troublesome weeds in his own garden (judging from its situation) at the same time.

Having had my grumble, I will not multiply examples, but conclude by mentioning one change of name that must have come as a great relief to many. I mean when the authorities re-christened the *Imantophyllum*, thus incidentally getting over a difficulty in the treatment of the poor letter "H," a difficulty which always reminded me of the old story of the American who had his cards printed "Awkins" for use in London, and was consequently generally addressed correctly.

A. K.

## NOTES OF THE WEEK.

**Carnation Countess of Far's** has done remarkably well here, and I do not know of a more profitable variety for cutting. Last spring I had a house full of plants in bloom in 6 inch and 7-inch pots, quite a sight. Some flowers were quite as fine as those of *Malmaison* and bright pink.—H. BECKER, *Jersay*.

**Aster cabulicus.**—There is a clerical error in the printing of Mr. Baker's note on p. 495 which has probably escaped his notice, and as it is adopted by "J. C. L." on p. 550, it is as well that it should be corrected. The modern synonym of *Aster cabulicus* is *Imeroglossa albescens*, a name which does not exist in botany, but *Microglossa albescens* (see Hooker's "Flora of British India," vol. iii., page 257).—C. W. DON, *Edge Hall, Malpas*.

**The season in Worcestershire.**—If the present abnormally mild and spring-like weather continues, the banks and copses will soon be all aglow with Primroses. Already there are quantities of blooms to be seen. Snowdrops are pushing through the soil fast, and will soon be in full flower. Even the *Daffodils* are showing up. Several good blooms of *Rose Gloire de Dijon* are also to be seen on a bush in a sheltered nook.—A. YOUNG, *Abberley Hall, Stowport, Dec. 29*.

**Chrysanthemum Mme. Bergmann.**—I send you a bloom or two of that excellent late *Chrysanthemum Mme. Bergmann*, as I see no mention of it in "E. J.'s" article a fortnight ago. In growth and effect it is much like *Phœbus* now so popular, and, unlike that variety, which is so early, *Mme. Bergmann* is as late as any *Chrysanthemum* I know. The colour is so rich and full, that even that of *W. H. Lincoln* looks pale by its side.—EDWARD H. WOODALL, *St. Nicholas House, Scarborough*.

**Winter Sweet at Claremont.**—I think you will be interested in the enclosed good specimens of two distinct types of *Chimonanthus*. The form *grandiflorus* is very fine this year. The tree is a very old one, covering a stretch of wall 25 feet by 13 feet. Since the beginning of December it has been a mass of flower.—E. BURKELL, *Claremont*.

\* \* The flowers of each form are very large and show how well the soil and other conditions suit this most precious of winter-blooming shrubs.—ED.

**Desfontainea spinosa.**—I send you a flower of *Desfontainea spinosa* that you may see how long the plant continues in bloom. It has been growing in the pleasure grounds here more than thirty years and has not been without blooms since July. It usually continues blooming until the first sharp frost in the autumn, but the past autumn has been so very free from frost until now that the flowers have been uninjured. The plant, which is growing in red loam on a southern slope, is well sheltered by other shrubs.—JOHN GARLAND, *Killerton, Exeter*.

The word "scientist."—In the December number of *Science Gossip* a protest was entered against the use of the word "scientist," and opinions on the point have now been received from some well-known men. The Duke of Argyll,

Sir John Lubbock, Lord Rayleigh, Professor Huxley, and Dr. Albert Günther unreservedly condemn the word. Lord Rayleigh approves Lord Kelvin's proposal to revert to the wider meaning of "naturalist," while Dr. Günther sarcastically suggests that "scientist" might advantageously be reserved to denote the modern dabblers in great scientific questions. Professor Huxley thinks "scientist" must be "about as pleasing as 'electrocution'" to anyone who respects the English language.

\* \* We are pleased this odious and needless word has been disowned by some of our best scientific men. Perhaps they will some day repudiate the very loose way in which the word "science" itself is used by many people.—ED.

**Hypericum patulum.**—Though I have a very great respect for Mr. Archer-Hind's knowledge and judgment of hardy plants, I have never been able to agree with him in his opinion that the *Hypericum patulum* of Sir J. Hooker (*Botanical Magazine*, tab. 5693, and "Flora of British India," vol. i., 254) and of modern gardens is not the *H. patulum* of Thunberg's "Flora Japonica" (295, Icon. 17). Sir J. Hooker tells us that it is "a native of Japan, discovered by Thunberg, and introduced into Kew by Mr. Oldham, collector for the Royal Gardens, who perished of fever on the coast of China." Some years ago I examined Thunberg's portrait of the plant, and made inquiries at the Royal Herbarium whether any doubt was felt there as to the identity of Sir J. Hooker's plant, and was told that there was none. That there has been some confusion in botanical works between *H. uralum*, *H. patulum* and *H. oblongifolium* is evident to anyone who examines the character and synonyms given. De Candolle ("Prodromus," vol. i., p. 545, A.D. 1824) agrees with Thunberg in his description of *H. patulum*, identifying it with *H. uralum* of Don, and also describes another variety of the same species. Even if Sir J. Hooker could have been mistaken in recognising the characters, it is unlikely that a shrub so easily raised from seed, as I have found all this section of *Hypericum* to be, should be unknown in English gardens in spite of our multiplied communication with Japan in horticultural matters.—C. W. DON, *Edge Hall, Malpas*.

**The weather in West Herts.**—The mild weather, which had continued without a break during the previous three weeks, suddenly came to an end on December 29, since which time low temperatures have prevailed. On Saturday in last week the highest reading in shade was 46°, but on Monday and Tuesday the temperature at no time exceeded 34°. On Tuesday night the exposed thermometer showed 14° of frost, which is the lowest reading as yet registered by the same instrument this winter. At the present time the temperature of the soil stands at 39° at 2 feet, and at 35° at 1 foot deep, both readings being very similar to those recorded at the same date last year. Snow fell for the first time during the present winter on Saturday. There was also another fall on Tuesday night, but on neither occasion was there sufficient snow to completely cover the ground. On Saturday the wind reached the strength of a gale, but the velocity for no single hour exceeded thirty-one miles. As in the case of the gale which occurred just a week previously, the strongest gusts came from due west. December proved a very mild winter month. Rain fell on nineteen days, and to the total depth of nearly 2½ inches, or about the average quantity for the month. During the year 1894 thirty inches of rain fell, which is only about half an inch in excess of the mean fall for the previous thirty-eight years.—E. M., *Berkhamsted*.

**The Royal Gardeners' Orphan Fund.**—The executive committee held a meeting at the Hotel Windsor on the 28th ult., Mr. W. Marshall presiding, there being a full attendance. The following special subscriptions were announced: The Altrincham Gardeners' Society, proceeds of an entertainment per Mr. C. Hewett, £50 10s.; the Scottish Horticultural Association, £5; Bris-

tol *Chrysanthemum* Society, sale of flowers, per Mr. J. Vallance, £5 5s.; the Stockport *Chrysanthemum* Society, £2 2s.; the Ware District Gardeners' Mutual Improvement Society, £1 2s.; Mr. J. Rogers, Ware, 5s.; Mr. G. R. Allis, Old Warden Park, Biggleswade, 5s.; and Mrs. Bowerman, Hackwood Park, Basingstoke, 5s. The following sums were from boxes: Mr. J. Burn, Abbey Park, Leicester, £7 5s.; Mr. J. B. Stevenson, Bournemouth, £1 7s. 2d.; Mr. H. A. Burbury, Birmingham, £1 10s.; Mr. J. H. Witty, Nunhead, £1 3s.; Mr. A. J. Brown, Chertsey, 13s. 6d.; Mr. H. Herbst, Kew Road, Surrey, £5 5s.; and Messrs. W. Thomson and Son, Clovenfords, £3 13s. A letter was read from Mr. George Bunyard, Maidstone, resigning his seat on the committee in consequence of inability to attend the meetings. A draft financial statement was furnished by the honorary secretary, which was considered satisfactory. Notice of motion was given to amend the rules at the annual general meeting in one or two particulars. The new applications from candidates desirous of being placed upon the fund were finally considered and approved. The allowances to the orphans for the first quarter in the present year were ordered to be paid. A hearty vote of thanks was passed to the chairman for presiding.

## OBITUARY.

### MR. C. COLLINS.

MANY gardeners and nurserymen will hear with great regret of the sudden death of Mr. C. Collins, a member of the staff of the *Journal of Horticulture*. On Christmas Day Mr. Collins was in his usual health, but it appears he had been warned by a medical man not to over-exert himself as he suffered from heart disease. He died entering a railway carriage at Forest Gate Station on Boxing Day last while carrying one of his children in his arms. Mr. Collins was born at Otterbourne, in Hampshire, and had gained experience in several good gardens, the last place he filled previously to joining the horticultural press being at Howick Castle. He first joined the *Horticultural Times*, then *Amateur Gardening*, then the *Gardeners' Chronicle*, and finally the *Journal of Horticulture*. We have known Mr. Collins for many years, and our sympathy is with his family in their bereavement. He was about thirty years of age, and we understand, insured in small societies. Unfortunately, his death occurred too soon to realise much benefit from one important office. He was a member of the United Horticultural Benefit and Provident Society, but had joined only recently.

## TRADE NOTES.

WE learn that Her Majesty's Commissioners of Woods and Forests have commissioned Messrs. Clibran and Son, of Altrincham, and of the Principality Nurseries, Llandudno Junction, to carry out the planting of Crown lands in Wales. The work is now in progress under the supervision of Mr. T. Lewis, Jr.

## BOOKS RECEIVED.

"Practical Forestry." Second edition. A. D. Webster. Rider and Son, London, E.C.

"Transactions of the Royal Scottish Arboricultural Society."

"Report of Proceedings of Viola Conference at Birmingham, August 3, 1894."

"Glenny's Garden Almanack." Illustrated by I. Ward, Lock, Bowden and Co.

**Erica ramulosa.**—Can any reader tell me in what nursery in England or elsewhere I can obtain this plant.—J. V.

**Names of plants.**—*J. H. Nicholson*,—1, *Cypripedium insigne*, ordinary form; 2, too small to identify.—*Jas. Davidson*,—*Masdevallia Chimera*.—*Danm.*—Specimen too far gone to identify.

No. 1208. SATURDAY, January 12, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHIDS.

## CATTLEYA PERCIVALIANA.

This is one of the most useful of all Cattleyas, for it flowers always in midwinter. The flowers are somewhat smaller than those of any other species belonging to the labiata group, but to compensate for this they are very brilliant and vary considerably. They appear during the months of December and January, a very serviceable time, for it enables the keeping up of a continuance of blooms after those of *C. labiata* vera are past and before those of *C. Trianae* can be expected to open. Compared with others of this group, *C. Percivaliana* is of comparatively recent introduction, and for this, credit is due to Mr. Sander, of St. Albans, whose collectors first discovered it and sent plants home about twelve years ago. Its natural habitat is in South-west Venezuela, where it is said to grow upon bare rocks fully exposed to the sun's rays at about 4000 feet elevation and mostly in close proximity to the rivers. From this we may gather that this species enjoys a plentiful supply of water during its season of growth. This species has been introduced in considerable quantities since it first became known. I believe amongst this first lot there unfortunately was a large percentage of what may be termed inferior varieties, all of which, however, were well worth growing.

Probably through some want of knowledge as to its treatment in this country the flowers were at one time often found not to open well, and this caused the species to have a bad reputation. During the past few years the blooms have fully developed, and the rich shades on the labellum have materially added to its beauty. This fine species was named in honour of Mr. R. P. Percival, of Birkdale, Southport, who at one time possessed a very fine collection of Orchids. In growth this plant greatly resembles *C. Mossiae*, and has oblong, furrowed pseudo-bulbs, which grow to about a foot in height, and are furnished with solitary oblong leaves of a deep green colour. The flowers are smaller than those of *C. Mossiae* and the smallest in this section, although they individually measure between 4 inches and 5 inches across, and are borne several upon a spike. As is usual with most members of this genus, the flowers of this kind are found to vary considerably in colour and markings. Thus there are to be found some with very pale segments, whilst others are distinguished by their deep colour and yellow markings in the throat. A good typical form may be described as having the sepals and petals of a purplish rose, the latter mostly more deeply coloured and much broader than the former; the side lobes of the lip are of the same shade as the petals, striated with dull orange; the front lobe beautifully frilled and of a rich magenta-crimson, blotched more or less with maroon and streaked with golden yellow; the throat yellow, into which run some purple lines. Amongst the numerous plants which have arrived in this country, there has been introduced a most chaste and beautiful albino variety which, as known in our gardens as *C. Percivaliana alba*. The first plant of the white variety that flowered was in the collection of Mr. Percival in 1884. It has entirely pure

white blooms with the exception of a yellow stain in the throat. This, however, is exceedingly scarce. W. HUGH GOWER.

**Dendrobium nobile** (*T. Marshall*).—There is nothing unusual in having this in flower at this season, for although somewhat early, I have recently seen a quantity in Covent Garden Market. By properly ripening the bulbs and giving them a thorough rest, the plants may be placed in heat and had in bloom by Christmas time, and where a number of plants are grown, a fine succession of flowers is easily obtained by proper treatment. It is impossible to say whether you have a good or bad variety unless you send a bloom.—W. H. G.

**Oncidium ornithorrhynchum**.—This very beautiful and useful plant produces its long spikes of many flowers very freely during the autumn and winter months. These individually are not large, but produced in great quantities. A specimen of the pure white form, which is very scarce, was recently exhibited at a meeting of the Royal Horticultural Society with seventeen grand spikes, which carried nearly 1700 flowers. In the typical plant the flowers are of a clear pale rose and have a sweet fragrance. It is a native of Mexico and Guatemala, and enjoys cool treatment under cultivation. Never allow the plant to become dry at any time, as it requires no decided period of rest.—W. H. G.

**Cypripedium Curtisi** (*T. Marshall*).—This *Cypripedium* was discovered by the collector whose name it bears and sent to Messrs. Veitch, of Chelsea, from Sumatra about twelve years ago. It is similar to *C. ciliolare*, but perfectly distinct, and has been used with some good results in the raising of new hybrids. The flowers are large, the dorsal sepal small, white, heavily veined with green; the petals brownish purple, becoming greenish towards the ends, and deflexed; the large lip of a dull dark purple. Possibly your plant is a hybrid from this kind.—W.

**Cypripedium Spicerianum**.—This is now flowering in many collections, its distinct shape and colour making it very welcome. It first became known to us in 1878 through Mr. H. Spicer, but was soon imported in considerable numbers by various firms from Assam. In growth the plant greatly resembles *C. insigne*, and the flowers vary in their shades of green and brown. The dorsal sepal is nearly entirely white, having only a small portion of the base green, with a very pronounced central line of deep purple. This character is also very prominent in the greenish petals, which are also deeply undulated at the margins. Being of such a distinct character it was eagerly sought after by the hybridiser, and has been used largely with marked success.—G.

**Odontoglossum coronarium**.—This, although it has been grown in our gardens for a number of years, flowers very unsatisfactorily, except in a few collections. It first became known over forty years ago, and is a native of New Grenada, where it grows at a considerable elevation. The blooms, produced upon a many-flowered raceme a foot or more in length, are each over 2 inches across; the sepals and petals of a bright reddish brown, margined with yellow and very shining; the small lip bright yellow. The plants should be placed in the cool house near the roof, and never be allowed to become dry at any season. It is known on the Continent as *O. candelabrum*.—G.

**Wintering Calanthes**.—Being successful in cultivating the very useful, early winter-flowering section of *Calanthes*, I wish to draw attention to an error which is often made with the pseudo-bulbs during the winter or resting season, and that is, subjecting them to too low a temperature, and also placing them in too dark a position. The pseudo-bulbs being leafless, it must not be imagined that they may be stored in out-of-the-way places, almost like Dutch bulbs, as if so, even though they may remain plump, they start away very feebly and are not to be compared with

others which have been rested in a warm temperature. Being fairly well off for house room, I allow them to remain well exposed to the light in the structure where they have been grown and flowered. Some of the pseudo-bulbs are also wintered on a warm and dry shelf near the glass in a lean-to plant stove. The bulbs are also allowed to remain in the pots or baskets as grown. Under this treatment the plants start away strongly, being in this respect quite unlike any which are shaken out of the soil after flowering with the idea of storing in a smaller compass.—A. YOUNG.

**Odontoglossum læve**.—From "W. C. M." comes a bloom of this under the name of *Odontoglossum Schroderianum*, which is a far superior and much rarer kind than *O. læve*. In the flower before me, which measures about 2 inches in diameter, the sepals and petals are light brown, barred with yellow, whilst the small flat lip is rosy lilac. This species is an old inhabitant of our gardens and is a native of Mexico, requiring quite cool treatment. It is one of the least showy kinds in this genus, and it is curious that it should have been imported for *O. Schroderianum*. This is the second occasion during the past month or two that I have seen *O. læve* called *O. Schroderianum*.—W.

**Dendrobium aureum**.—This fine old *Dendrobium*, which is better known in our gardens under the name of *D. heterocarpum*, is now flowering profusely with Messrs. Laing and Sons, of the Forest Hill nurseries, quite small plants being completely covered with bloom. The flowers are produced from the upper nodes of the two and three-year-old stems; therefore the annual pruning of this species should not be attempted. The colour of the sepals and petals is creamy white, and the lip is tawny yellow, streaked with red, and velvety purple on the disc. This is a very desirable plant, the flowers lasting a considerable time in full beauty and emitting a pleasant fragrance.—G.

**Cymbidium Lowianum**.—I am in receipt of a bloom of this fine species from George Ford on an opinion. It can only be described as a pale form; the lip is light red, which is by no means uncommon, and the sepals and petals are quite green. In the best varieties these latter approach deep yellow, and the blotch on the lip is of a deep reddish crimson. It appears to be rather early for this plant to be in bloom, the usual time being about a month hence. I have recently noticed some exceedingly fine examples, but the blooms will not be expanded until February or March. The flowers will last two months and even longer in perfection, and often upwards of thirty are borne upon a spike.—W. G.

**Cypripedium Leeanum superbum**.—A remarkably fine variety of this splendid hybrid is now in flower in Messrs. Laing and Sons' nurseries, Forest Hill. It is the result of crossing *C. insigne* Maulei with *C. Spicerianum*, and is far superior to the ordinary form, which is a hybrid from the typical form of *C. insigne*. During the present season I have noticed a number of seedlings in flower at various establishments from this parentage, and resulting in many varieties, none of which, however, are distinct enough for varietal names. The plant in question has a very fine dorsal sepal, the spots being of nice colour, the whole flower large and of good substance.—W.

## ODONTOGLOSSUM CERVANTESI AND VARIETIES.

**ODONTOGLOSSUM CERVANTESI** is a dwarf-growing species, flowering during the winter months. It is easily grown and therefore very suitable for amateurs. The best way to grow it is to suspend it in shallow pans close to the roof of the cool house. When so placed it succeeds far better than when grown on the stages with other kinds. The potting compost should consist of fibrous peat and Sphagnum Moss, and care must be taken that the drainage is in thorough order, for if allowed to get into bad condition these small-growing

kinds soon dwindle away. When potting the plants raise them well up on a mound-like cone. This pretty little species was introduced into this country in a living state from Mexico by the late Messrs. Loddiges, of Hackney. The pseudo-bulbs are small and furnished with solitary oblong leaves, each about 4 inches or 5 inches in length. The flowers, produced from four to six upon a scape, are each nearly 2 inches in diameter. The petals are much broader than the sepals, both pure white, transversely streaked around the base with broken lines of reddish brown; the lip is broad, with finely undulated margin and pure white.

*O. CERVANTESI DECORUM*.—This magnificent variety of the typical form first appeared, I believe, in the collection of Sir Trevor Lawrence, Bart., at Dorking. In this form the flowers are very much larger and all the segments broader, the broken lines are more numerous and of a deeper shade, whilst the large lip is deeply bi-lobed and finely cut at the margin, the streaks on the disc being of a purplish colour.

*O. CERVANTESI MEMBRANACEUM*.—This charming little kind differs somewhat from the type and was described by Dr. Lindley in 1838. It produces a raceme of several flowers, which are sometimes white and sometimes of a rose colour, with the usual characteristic broken lines on the sepals and petals, which are also produced slightly upon the bluntly cordate lip.

These form a very nice little group, to which should be added *O. Gerstedti*, *O. Krameri*, *O. Rossi* with its varieties, and others, which all succeed well under similar treatment.

WM. HUGH GOWER.

#### SHORT NOTES.—ORCHIDS.

*Cypripedium Youngianum superbum*.—Under this name I recently noticed a very distinct plant in bloom in the Cambridge Lodge collection. It was supposed to be the result of crossing *C. flavigatum* with *C. ciliolare*, and has the dorsal sepal very heavily veined, the deeply coloured drooping petals being very thickly spotted.—W. G.

*Cypripedium callosum sublæve*.—This is a distinct form of this beautiful species, and, according to the late Professor Reichenbach, is a hybrid between *C. callosum* and *C. Hookeri*. The petals are of a fine purplish-rose colour, and the lip is also suffused with rose. A very nice variety is at present in flower at Messrs. Peed and Son's Roupell Park Nurseries, Norwood.—G.

*Cypripedium Boxalliatratum*.—This is one of the finest varieties of this beautiful species. It is a native of the Tongu district, in Moulmein, the individual blooms being large, of good substance, and quite shiny in appearance, as in *C. villosum*. In the variety atratum the dorsal sepal is larger and more heavily blotched with black, whilst the petals are broader and much lighter in colour.—W.

*Masdevallia Gairiana*.—A beautiful hybrid *Masdevallia* of Veitchian origin, obtained by crossing *M. Veitchiana* with *M. Davisii*. It grows to about 4 inches or 5 inches in height and has slightly arching foliage. The colour of the flower is reddish orange, spotted principally upon the upper sepal with mauve-coloured warts. It is a decided addition to this genus, and was first flowered about ten years ago.—W.

*The Dove Orchid* (*Peristeria elata*) (*T. W. O.*).—This is the name of your plant, and it will attain a height of from 3 feet to 4 feet when well grown. The flowers will open about July or August and continue in perfection for two months. The spike grows even higher than the foliage. At the present season this species must be kept quite dry. When growth commences water must be given with care. Place it in the Cattleya house.—G.

*Odontoglossum præstans*. Under this name comes a flower of an *Odontoglossum* from George Woodhouse. This has lanceolate sepals and petals, greenish yellow, tapering sharply at the points, and spotted and blotched with dull brown; the lip and column white, the former having a brown blotch upon the centre and with a pale yellow crest. It is a very nice flower, but I should take it to be a form of *O. gloriosum*.—W.

*Lælia Perrini*.—This fine autumn-flowering kind seldom attains more than 1 foot in height. The flowers

each measure about 6 inches across and are of a pale rosy magenta, with a deep, rich crimson-purple lip. There is also a charming variety of this plant named *L. Perrini nivea*, which flowers at the same season—October to December. In this the sepals and petals are white, as are also the side lobes of the lip, the front lobe being pale rose. It is a beautiful companion to the typical form.—W.

*Odontoglossum crispum* (*Beginner*).—Undoubtedly this is the most useful and most extensively grown *Odontoglossum* in cultivation. It is, however, not advisable to try to hurry this plant into bloom at the present season, for the spikes appear to make up better if produced a little later on, and will then be safer from the fog. This has probably been the cause of your blooms fading so quickly. The pure white form is very chaste and beautiful, but the best and most valuable varieties are those which are spotted and suffused with deep rose.—W.

## TREES AND SHRUBS.

### THE BAMBOO GARDEN.

#### FUTURE POSSIBILITIES.

No one who has realised the great and unexpected successes which have already been attained in the cultivation or acclimatisation of Bamboos can doubt that much more remains to be achieved, and that the possibilities are far from being exhausted. When we consider that both in Asia and in South America there are Bamboos growing at almost incredible altitudes, that among the Andes, for instance, there is one species at least—*Chusquea aristata*—to be found at a height corresponding to the top of Mont Blanc, we are encouraged to believe that enterprise will, in the near future, enrich our gardens with many a new beauty. Then there is the evidence of the tessellation of the leaf veins, to which I have already alluded. For this evidence I do not claim more value than is afforded by the simple fact that no Bamboo without this character has proved thoroughly hardy in this country. It is certain that there are tropical Bamboos with tessellated venation which we could not hope to grow, and therefore the test is an incomplete one. But when we find it combined with a natural habitat of great altitude and in plants surrounded by a non-tropical vegetation, we have good reason to put faith in the hardiness of the species and a warranty for trying to acclimatise it here. It must, however, be remembered that altitudes in tropical climates by no means represent the same temperature that they do in Europe. I am assured that in Madras and Ceylon snow does not fall below 9000 feet above the sea; that in Khasia it does not fall below 7000 feet; in Sikkim below 6000 feet; and that at a height of 5000 feet the vegetation of Tenasserim is sub-tropical. But when all these facts are taken into consideration it is still certain that the Himalayas are full of treasures which we as yet do not possess. Eminent botanists are at the present moment busy with the matter, and when Mr. Gamble's great monograph on Indian Bamboos appears, under the auspices of the Indian Government, a totally new light will be thrown upon the subject.

The exploration of the Andes is a more difficult matter, yet they are rich in species

with tessellated leaves growing at heights from 4000 feet to 15,000 feet above the sea level, and assuredly they should be laid under contribution. The great difficulty will be that the absence of great botanical establishments such as those of India must throw the task of investigation upon private enterprise.

Africa is, so far as is at present known, a less promising field for the collector of hardy Bamboos; but it must be remembered that hitherto the chief authority to which we look is General Munro's "Monograph," which appeared in 1866, when the Dark Continent was still an unexplored fable-land. It is probable that since the European Powers have penetrated its most hidden recesses many botanical secrets, undreamt of in our philosophy of a few years ago, will be revealed.

Whether China and Japan can yield us much more than they have hitherto done is to me doubtful. We possess already no fewer than forty distinct species of hardy Bamboos from that source. Both the Chinese and Japanese are excellent gardeners and cultivators, trained by heredity in the art of adapting and improving plants. From time immemorial they have been engaged in ransacking their native forests and mountains for the enrichment of their pleasure grounds, and it is not likely that such sharp eyes should have passed by any species of conspicuous merit in a genus which, in their view, is the type of all that is most graceful and most poetical in plant life. Moreover, they are essentially practical people, to whom the commercial and utilitarian value of the Bamboo appeals with the chink of dollars. For these reasons I am inclined to think that we shall not get many new varieties from their gardens. To many of these gardens our European collectors have for some years had free access, and have thus had before them a living catalogue of the daintiest and loveliest species, with the result shown by the enumeration given in previous chapters. On the other hand, it must be remembered that the flora of China especially is one of the richest in the world, that our botanists are only now beginning to examine it by the light of Western science, and that therefore it is dangerous to hazard any very definite opinion in regard to it. One of our greatest botanists writes to me: "The flora of North-western China is essentially Himalayan, with a profusion of distinct *Rhododendrons*; why not, then, of hardy Bamboos?"

With a view, then, of calling the attention of our collectors in various parts of the world to the subject, I have drawn up a list of those plants described by Munro which appear to be the most likely to succeed in this country, and to which the numerous expeditions sent out in search of Orchids and other rare plants might, in passing, profitably turn their attention.

I am aware that my list errs on the side of hopefulness. A trial, at any rate, will do no harm, even though some species should be sentenced to death, others to imprisonment in the temperate house; while every new plant flourishing in freedom will be a real treasure gained to our gardens—in every sense a sur-

vival of the fittest. Many of them, no doubt, will only find a congenial home in the warmest nooks of our islands, but some there are which may assuredly settle down comfortably among their Chinese and Japanese cousins in the ordinary English climate.

Here is an index, taken by continents, of some of the species which I should wish to see introduced, together with many others unknown hitherto undescribed. Those marked with an asterisk are to be found in the Kew collection, but none, so far as I know, are as yet in commerce:—

ASIA.

- \**ARUNDINARIA RACEMOSA* (Munro).—Native name Pat-hioo. Tessellated leaves. 5000 feet to 12,000 feet. N.E. Himalayas.
- A. *WRIGHTIANA* (Nees).—Tessellated leaves. Nilghiri Mountains.
- A. *LONGIRAMEA* (Munro).—Tessellated leaves. Hong Kong.
- A. *FLORIBUNDA* (Munro).—Tessellated leaves. Ceylon.
- A. *GRIFFITHIANA* (Munro).—Tessellated leaves. Khasian Hills.
- A. *WALKERIANA* (Munro).—Tessellated leaves. Adam's Peak, Ceylon.
- A. *DEBILIS* (Thwaites).—Habitat 6000 feet to 8000 feet above sea. Ceylon.
- A. *INTERMEDIA* (Munro).—Sikkim. 7000 feet to 8000 feet above sea.
- \*A. *HOOKERIANA* (Munro).—Native name Praong (Hooker). Sikkim. 4000 feet to 6800 feet above sea.
- A. *ARISTATA* (Gamble).—9500 feet to 11,000 feet above sea. N.E. Himalayas. Not described by Munro.
- A. *PRAJNI* (Gamble).—3500 feet to 7800 feet above sea. Naga Hills, Upper Assam. Not described by Munro.
- A. *CALLOSA* (Munro).—Tessellated leaves. "Prickly-jointed Bamboo." Native name Uskong (Hooker). 6000 feet above sea. Khasian Hills.
- A. *HIRSUTA* (Munro).—Tessellated leaves. 6000 feet above sea. Khasian Hills. "Spinous stems" (Hooker).
- A. *MICROPHYLLA* (Munro).—Tessellated leaves. 6000 feet to 10,000 feet above sea. N.E. Himalayas.
- A. *ROLLOANA* (Gamble).—5000 feet to 7000 feet above sea. Naga Hills. Not described by Munro.
- A. *JAUNSARENSIS* (Gamble).—7000 feet to 8000 feet above sea. N.W. Himalayas. Not described by Munro.
- \**THAMNOCALAMUS SPATHIFLORUS* (Munro).—Conspicuously tessellated leaves. 8500 feet to 10,000 feet above sea. Nepal, Sikkim, Bootan. (Note.—Several cultivators have a plant with striated leaves wrongly sent out under this name.)
- PHYLLOSTACHYS STAUNTONI* (Munro).—Tessellated leaves. China.
- BAMBUSA NUTANS* (Wallich).—5000 feet to 7000 feet above sea. Nepal, Silhet, Khasia, Assam, Sikkim. Native name in Sikkim, "Mahlo."
- B. *GRIFFITHIANA* (Munro).—Tessellated leaves. Only once found by Griffith in the extreme north of Burmah, associated with numerous tropical plants. Only in-erred here on account of the tessellation. Probably not hardy.
- B. *CANTORI* (Munro).—Tessellated leaves. China.
- B. *AFUS* (Schultes).—Tessellated leaves. Mount Salak, Java.
- B. *CORNUTA* (Munro).—Tessellated leaves. Java. Native name, "Tring embon."
- B. *RICHEYI* (Munro).—Tessellated leaves. Bombay, below the fall of the Kala Nuddi. Native name, "Choomaree."
- B. *MASTERSII* (Munro).—Tessellated leaves. Assam, Dibronghur. Native name, "Bentibans."
- \**CEPHALOSTACHYUM CAPITATUM* (Munro).—Tessellated leaves. 4000 feet to 5000 feet above sea. Khasia, Sikkim.
- C. *PALLIDUM* (Munro).—India, Mishmee, Burmah, Patkaye. 5000 feet above sea. Native name, "Beteo Bans."

*DINCHLOA TJANKORREH* (Buse).—Inconspicuous tessellation. Philippine Islands, and 4000 feet above sea in Java, Mount Salak.

AFRICA.

- ARUNDINARIA TESSELLATA* (Munro).—Tessellated leaves. 500 feet to 6500 feet above sea. Mount Winterberg, Caffre-land, Mount Katberg. Closely resembling the *Arundinaria macrosperma* of North America.
- NASTUS BORBONICUS* (Kunth).—Tessellated leaves. Alpine, 1000 feet to 3000 feet above sea. Island of Bourbon or Réunion.
- CEPHALOSTACHYUM CHAPELIERI* (Munro).—Tessellated leaves. Madagascar. A climbing stem.

SOUTH AMERICA.

- ARUNDINARIA RADIATA* (Ruprecht).—Tessellated leaves. The forests of Brazil.
- A. *AMPLISSIMA* (Nees).—Brazil. 4000 feet to 5000 feet above sea.
- ARTHROSTYLIUM LONGIFOLIUM* (Munro).—6000 feet above sea. Venezuela.
- A. *SCHOMBURGI* (Munro).—6000 feet above sea. Guiana. Native name, "Curata." Lowest internodes 12 feet to 16 feet long.
- CHUSQUEA ULCIGINOSA* (Philippi).—Tessellated leaves. Chili, Valparaiso.
- C. *ANDINA* (Philippi).—Tessellated leaves. Andes, on the fringe of the perpetual snow.
- C. *CULEOR* (Gay, "Flora Chili").—Tessellated leaves. Chili.
- C. *TESSELLATA* (Munro).—Conspicuously tessellated leaves. Andes of Bogota. ? = *Bambusa disticha*.
- C. *ARISTATA* (Munro).—Conspicuously tessellated leaves. 13,000 feet to 15,000 feet above sea in the Andes, Ecuador, Quito.
- C. *FENDLERI* (Munro).—6000 feet to 12,000 feet above sea. Venezuela, Ecuador.
- C. *DOMBEYANA* (Kunth).—6000 feet above sea. Peru, New Grenada, Bogota, Tolima, Ecuador.
- C. *QUILA* (Kunth).—Tessellated leaves. Chili, Valparaiso, Valdivia, Chiloe.
- C. *SELLOVII* (Ruprecht).—Tessellated leaves. Brazil.
- C. *GAUDICHAUDII* (Kunth).—Tessellated leaves. Rio de Janeiro.
- C. *CAPITULIFLORA* (Trinius).—Tessellated leaves. Brazil, Rio de Janeiro. Native name "Quixiume."
- C. *CAPITATA* (Nees).—Tessellated leaves. Brazil.
- NASTUS BARBATUS* (Ruprecht).—Tessellated leaves. Mountain forests of Brazil.
- GUADUA ANGSTIFOLIA* (Kunth).—Tessellated leaves. 2400 feet above sea. Western slope of Andes, New Grenada, La Paila, Bogota, Ecuador, Peru.
- G. *AMPLEXIFOLIA* (Presl).—Tessellated leaves. 2000 feet above sea. Mexico, Santa Cruz, New Grenada, Venezuela.

**Scotch Laburnum.**—Those who are fond of Laburnum should not fail to plant this, seeing it has many advantages over the common kind. It is much later in coming into bloom, and also bears much longer racemes of flower. The foliage, too, is much larger and more shining. I also find it much freer growing. Many of the trusses of bloom last summer were over a foot in length.—DORSET.

**Osmanthus ilicifolius.**—This dwarf evergreen shrub of Holly-like appearance is one of the most useful of the many good things introduced from Japan by John Gould Veitch more than a quarter of a century ago. It often takes many years before the actual value of an introduction of this kind can be fully estimated; it has been so in this case. This *Osmanthus*, moreover, is coming into favour as a plant for town gardens both for boxes and in the open ground. Having once proved its hardiness, it is no wonder that increased inquiries are being made for it. Its dwarf compact habit makes it preferable to the good old *Mahonia aquifolia*, from the simple fact that it will lift with a good ball of soil; whereas the latter will not. Its lustrous Holly-like leaves do not accumulate the sooty deposits beyond the possibility of cleansing. As a front row plant or for massing it is excellent, making also a good

groundwork to taller things of deciduous character. For planting upon rockwork it is also admirable, taking some few years before it will out-grow its position. I have not tried the dwarf variegated form (*O. ilicifolius variegatus nanus*), a most distinct acquisition, and hardly also beyond a doubt. There are also both a silver and a golden variety, and another with a metallic purple shading on the leaves, a very distinct form.—S.

THE TULIP TREE.

(*LIRIODENDRON TULIPIFERA*.)

THIS is one of the very finest flowering trees that have been brought from North America, numerous as those have been. It is the only species in the genus and is nearly allied to the Magnolias. It is spread widely over the North American continent, reaching in the most suitable localities a height of 140 feet, with a trunk 5 feet to 6 feet in diameter. For English parks and large gardens, more especially in the south, it may be strongly recommended, being of elegant, yet stately growth and carrying an abundant canopy of foliage. The leaves, borne on long petioles, are very distinctly four-lobed, each lobe ending in a rounded point; the terminal part has the appearance of having been cut off. The shape of the leaf is, however, subject to considerable variation. In some forms the four main lobes are again divided; in others the lobes are reduced to two. The flowers are solitary and in size and shape have some resemblance to a Lily—a likeness implied in the name of *Liriodendron*. They are eup-shaped and made up of three sepals, which are reflexed, and six erect petals, which on the outside are greenish yellow, but marked inside with a spot of bright orange. A large tree thickly studded over with bloom has a very striking appearance; the flowers are at their best in June and July. Trees raised from seed do not as a rule flower in this country until they are more than twenty years old. Like its near allies, the Magnolias, the Tulip Tree is impatient of disturbance at the root when once it has become established. It should, in consequence, be planted in its permanent quarters as soon as possible, and whilst in the nursery it should not be allowed to remain more than two seasons without transplanting. In the matter of soil its requirements are similar to others of the Magnoliaceae family—a rich, moist loam, inclining rather to the heavy than the light side. There are two or three variegated forms of this tree in cultivation. In one a large proportion of the leaf is yellow; in the variety *aureo-marginatum* this colour is confined to the margins. In autumn the entire foliage of the tree before it falls turns to a brilliant golden yellow. It is, indeed, one of the finest of our autumn-tinted trees. B.

HOLLIES AND THEIR MUTILATION.

No evergreen tree or shrub suffers so much at this season of the year as the Holly in respect to cutting for Christmas decorations. It is not my purpose to enter into a discussion *pro* or *con* as regards the use of cut Evergreens at such times. It is rather to enter a protest against the wholesale destruction of Holly trees and shrubs, these being cut down and sent to market in immense quantities. It is not everyone, perhaps, who is a lover of shrubs that has an opportunity of inspecting the produce of this kind sent to market. In order to secure a large supply such as one sees in Covent Garden, it is not so much a matter of stumping off young trees or bushes as it is of lopping older ones that have taken years to grow. To see these lopped and backed about in an indiscriminate manner is simply grievous. No landowner should tolerate its being done, neither should those who have the charge of property permit it. As a hardy British Evergreen I do not consider the Holly has an equal, but if the cutting and lopping go on increasing, some districts at least will be deprived of their best examples. It is, on the other hand, possible in most instances

to take shoots here and there in a moderate way without doing any material harm. Unless the view in any particular direction is obstructed, I would never permit a Holly tree to be cut down. It is very rare that one will die a natural death, hence Hollies are all the more valuable. My practice in cutting Holly for nearly twenty years past has been to shorten overhanging branches, so as to admit more light to these underneath. In this way I have worked up a number of shapely plants into the pyramidal form, some with a broad base in proportion to the height, others more tapering, but well furnished to the ground. At first a few larger branches had to be shortened; now it is merely a matter of foreshortening. Some of the tallest of these trees are now nearly 30 feet in height, it not being an easy matter, even with the standard tree pruners, to reach their topmost shoots. I find, however, that now their growth is far more equal than it was, so much so in some instances that they grow naturally as pyramids without any training at all. Holly berries are most abundant this season, both the red and the yellow-fruited forms. I have never noted a prolific crop of berries, however, on Golden Queen or Silver Queen; to cut these in any quantities would be nothing less than barbarous. The inferior variegated forms berry freely. SOUTHON.

**Rhododendron dahuricum.**—The exceptionally mild weather experienced in the south up to the present (the middle of December) is showing its effects already in the flowering of this Rhododendron, which has for a fortnight past been in bloom in the sheltered Rhododendron dell at Kew. Its normal season is, however, in February. It is a native of Siberia, and was introduced into this country about the year 1780. It is a shrub of rather sparse growth, rarely seen in bushy form when old, and attains a height of 5 feet. The leaves are small and of a dark green; in the ordinary form they are deciduous, but in the variety called *atro-virens* they remain on the plant throughout the winter. The flowers, spread out almost flat, each measure  $1\frac{1}{2}$  inches in diameter, the colour being a bright, glowing rosy purple. The early flowering and perfect hardness of the species have led to its being used in hybridisation, one of the most popular and useful of its hybrids being *R. præcox*, raised from it and the Himalayan *R. ciliatum*.

**Olearia Haasti.**—I have been much struck with the appearance of this compact growing and most profuse flowering shrub during the past few seasons. Like *Osmanthus ilicifolius*, it is an increasingly popular plant. Its season of flowering is the latter part of July up to the end of August. Although it is deemed one of the hardiest of its genus and quite safe in most parts of this country, I would prefer to plant it in rather dry and elevated positions. If too moist at the root it is just possible that one of our most severe winters might affect it, it being borne in mind that it is an inhabitant of New Zealand, where this genus is known as the Daisy Trees. At Chiswick there is quite a large bush of this species in a position facing north. Thus far I have not seen it used as a seaside plant, but from its appearance I am most favourably disposed towards it by reason of its close, short-jointed, and sturdy habit—strong recommendations against the sea breezes. Another species, *O. macrodonta*, is recommended on the best authority as being more suitable even than the foregoing for this climate.—G. H. A.

**Mistletoe.**—As a marked contrast to the trouble taken in some places to secure a stock of Mistletoe, a friend was telling me lately that it multiplies so rapidly and easily with him as to be somewhat of a nuisance. Not content with remaining in the park, it found a resting-place some years ago on old espalier Apples, the result being a few nice bushes, which have to be strictly preserved. As an outcome, however, of the first invasion of the Apples, there is such a tendency to spread as to necessitate strict orders to carefully look for and cut out all freshly formed growths in

the bark at each annual winter pruning. I noticed the other day an instance of the self-propagation of the parasite on a Sugar Maple, which may be of interest to your readers, especially as this Aeer is not, I believe, among the list of trees which are usually ranked as Mistletoe trees. The tree in question is a nice specimen from 50 feet to 60 feet in height and with a proportionately well-furnished head, in the top of which five or six large bushes of Mistletoe have for a long time found a resting-place. Within the last two or three seasons—doubtless as a result of an exceptionally good crop of berries—little twigs of the parasite are in evidence all over the tree literally from top to bottom. Given a few years and fairly rapid development, this Maple will during the winter months be an interesting sight, evenly loaded throughout its height and breadth with the green bushes. An impression seems to exist that the presence of Mistletoe in quantity on any tree is highly detrimental. It may be so slightly, but not to any serious extent—not, I mean, shortening the life of the tree. The age and size of both Limes and Thorns that one occasionally sees quite in parts loaded with the parasite prove the contrary.—E. BURRELL, *Claremont*.

#### THE WAX MYRTLES OF THE SEA-COAST OF EASTERN NORTH AMERICA.

Those who have written specially of the plants of the Northern States have referred the common coast Myrica to the *Myrica cerifera* of Linnaeus without even a question as to its being a variety of that species. When the plants are seen growing, however, it is impossible to adopt this view, or admit that the northern and southern plants are varieties of one species. In describing the trees of this genus I shall follow Catesby, Miller and Elliott, and call the southern arborescent plant *Myrica cerifera*, and the northern shrubby plant, which also ranges far to the south, *Myrica carolinensis*.

**MYRICA CERIFERA** is a tree sometimes 40 feet in height, with a tall stem covered with pale smooth bark, and sometimes only a few inches thick, although occasionally more than a foot in diameter, and a narrow head of slender upright branches, which are usually forked towards the extremities. The leaves, which remain on the branches until after the appearance of those of the following year, are from  $2\frac{1}{2}$  inches to 3 inches in length, usually from a quarter of an inch to half an inch in width, and covered with bright golden resinous glands, which are so thick and conspicuous on the young foliage that it appears bright yellow. The leaves have a strong resinous smell, quite unlike the peculiar odour of the northern plant. The fruit is pale blue. It grows in low wet holes in the maritime Pine belt and in deep swamps near the coast under the shade of Red Maples, Cotton Gums, Sweet Gums and Bay trees; and where roads or openings have been made through them this tree may often be seen bending down along the margin of the forest, its long slender stem being unable to hold the head erect unless surrounded by other trees. I have found it near Cape Charles, in Virginia; it is very common on the coast and islands of the south Atlantic States from Cape Fear River south to the Florida keys and on the Gulf coast as far west, at least, as Berwick Bay, and probably farther, although I do not remember to have seen it on the Texas coast; it is said to grow on several of the Antilles, and I have collected it in Bermuda, where it is abundant. There is a form of this species (the variety *pumila* of Michaux) which grows in the Pine barrens of the south Atlantic and Gulf coast region, usually in rather low, slightly moist places not far from the margins of swamps. This is often only a foot high, but otherwise is not distinguishable from the arborescent form except in its narrower, smaller leaves and rather smaller fruit.

**MYRICA CAROLINENSIS** is a low shrub, usually not more than 2 feet or 3 feet high, which often forms broad, dense thickets. The leaves are from

$2\frac{1}{2}$  inches to  $3\frac{1}{2}$  inches long and three-quarters of an inch to  $1\frac{1}{2}$  inches wide. The resinous glands are smaller than those on the leaves of *Myrica cerifera*, and never abundant enough to give the foliage the yellow colour which is so marked in that species. The fruit is more than twice as large as that of *Myrica cerifera* and rather paler, although the colour of the fruit of both these plants varies considerably on different individuals. This is common on the shores of the Great Lakes and near the ocean from Southern Maine to Southern New Jersey, and at the north inhabits dry hilly and sandy shore dunes; south of New Jersey it is rare, although I have seen occasional isolated plants near Wilmington, North Carolina, at Bluffton, South Carolina, and near Mobile, growing in swamps with *Myrica cerifera*, and Dr. Chapman and Mr. Curtiss have collected it at Apalachicola, Florida.

**MYRICA INODORA** is a beautiful little tree with pale bark and dark green very lustrous persistent leaves, the fruit sometimes nearly a quarter of an inch in diameter. It was discovered by William Bartram in a swamp near Mobile, where it still grows, as well as in one or two others in the same region. It has been found near Apalachicola and is comparatively common on the Indian River, in Florida; but, although first described more than a century ago, it is still one of the least known of American trees.—*Garden and Forest*.

#### AUCUBAS.

NOTWITHSTANDING the large number of new varieties introduced from time to time (not so much perhaps of late years as from fifteen to twenty years back), *Aucuba japonica*, more correctly perhaps termed *Aucuba japonica maculata*, still heads the list as a shrubby plant of the first rank. In some districts, it is true, it does not thrive so well as one could wish, but these occurrences are extremely rare so far as I have personally taken notes. As an undergrowth to tall deciduous trees I would not be without this *Aucuba* on any account. For such purposes I consider it one of the best shrubs that can be planted. When the tall deciduous trees have cast their foliage, that of the *Aucuba* shines forth at its best. Some may possibly have failed when planting for this particular purpose where it has not been an easy matter to get anything to thrive. As regards the *Aucuba*, I find it is best to select yearling plants for massing or planting in any quantity in unfavourable positions. By this I mean either cuttings that have been rooted for about twelve months or layers of the same stage. Mine were the latter, the work of layering being done after the annual early winter cleaning out. These make capital dwarf stuff to plant straight away when well rooted, pegging down being practised for a season or two afterwards so as to cover the ground, which has now been done where previously it was well-nigh impossible to get anything to thrive, the large overhanging tree in this instance being an immense Horse Chestnut. Let the shrubs be what they may, deciduous or evergreen, it is in my opinion, from practical observation, far better to depend on quite young plants when grouping or massing has to be performed under the shade of trees, the ground around which is permeated with roots. Some planters may and do, I know, employ larger plants for this purpose, but I am fully persuaded that it is wrong in practice; it may take a less number, but these will of the two be the more expensive. The small ones with a fair attention to watering have a much better chance of succeeding. If it be sloping banks that have to be planted, the same argument still holds good. In the case of *Aucubas* (*i.e.*, the ordinary or common variety) I have noted particularly how easily they may be removed and transplanted at almost any season of the year, except when the young growth is quite tender. As stop-gaps, therefore, this makes it all the more desirable to have a stock of young plants in hand for filling up blank spaces.

G. H. A.

STOVE AND GREENHOUSE.

LILIUM SPECIOSUM IN POTS.

SOME Lilies are grown only to a very limited extent, while, on the hand, what may be regarded as popular species may be met with in almost every garden. To this latter class belong such as *L. Harrisii*, *L. tigrinum* and varieties, *L. umbellatum* or *davuricum*, as well as that figured in the accompanying illustration, *L. speciosum*, which is occasionally met with under the specific name of *laucifolium*. This, either in pots or in the open ground, may under favourable conditions be depended upon to do well. It usually blooms during the latter half of August and well on into September, but, of course, it is in this respect influenced by the season, as, for instance, in 1893, owing to the tropical weather then experienced, we had very few flowers after the middle of August. When in pots, it may if needed be had in bloom about the end of June or early part of July, but in

and the best sent from Japan are more than a month later: indeed, Japanese bulbs in splendid condition reach here up to the end of the second month in the new year. In potting the bulbs thorough drainage must be ensured, and where several are grown together in large pots, it is a very good plan to leave a space of 3 inches or 4 inches to allow of a top-dressing later on as the roots at the base of the flower-stem make their appearance. The bulbs should wherever possible be at such a depth that there is a couple of inches of soil over the top of the bulb, and when potted they may be stood outdoors on a bed of ashes and covered about 3 inches deep with the same material or with cocoanut refuse. This must be removed previous to their starting into growth. When required to flower under glass at the normal season they may be left out of doors till the buds are formed, but if a succession is needed some may be protected by a frame and given a greenhouse temperature as they develop. Good showy masses result when three bulbs are placed in a pot 10 inches in diameter, while

effectually, however, the old soil should be removed as far as the upper part of the bulb, for it will there be completely exhausted by the numerous roots produced from the lower part of the stem. In this way clumps of this Lily may often be kept in good condition for years, provided they receive proper attention. In commencing with imported bulbs a good plan is to obtain one's stock and get them all potted by Christmas. As good bulbs of *L. speciosum* can be obtained at a very cheap rate during the dormant season, it has been taken in hand by some of our market growers, and about July and August good examples of it may be seen hawked about the streets, and it is also a familiar object in the flower shops.

THE VARIETIES

of *L. speciosum*, if one may judge by some lists, are many, yet at the same time it must be borne in mind that names are more numerous than distinct forms, while dealers are by no means at one accord in this matter. Of those with white flowers there are four distinct kinds, viz., album, as grown by the Dutch, but which, as far as I know, does not occur among the Japanese importations. The bulbs of album are, as a rule, the darkest coloured of all, while the leaves are also of a very deep green, and the stems, leaf-stalks, and exterior of the buds tinged with chocolate. The interior of the flower is, however, pure white, though after it has been open for a day or two there is sometimes just a suspicion of pink. The variety *Kratzeri*, which is the one white imported in quantity from Japan, differs in many well-marked features from the preceding. The bulbs of *Kratzeri* are yellowish, while the leaves are of a paler green than those of the others. The petals reflex in a very symmetrical manner, and the interior of the flower is not entirely white, as a greenish stripe, which commences in the centre of the bloom, extends about half-way down the centre of each petal. The anthers of this are brown, and conspicuous against the rest of the flower. A second Japanese form is a very scarce one, and only crops up occasionally among importations of *Kratzeri*, from which it principally differs in the anthers being bright yellow. The petals are thick and massive and the flowers large, it being altogether a very desirable form. This variety is generally known under the name of album novum. The last of the white flowers to mention is a crested form of album. In this the stems are usually more or less fasciated, and the flowers disposed in a crowded cluster at the top. The individual blooms are, however, small and of a poor shape, so that it is by no means desirable. Flowers with the petals more or less coloured are very numerous, the best of all being that usually met with in nurserymen's catalogues under the name of *Melpomene*. It was at one time very scarce, but great numbers are now sent here from Japan every year, either separately or mixed with a good form of the variety *rubrum*. All those bearing the varietal name of *Melpomene* are by no means of equal merit, but the best form is characterised by very broad leaves, especially towards the upper part of the stem, and by dark, richly coloured blossoms, whose petals are clearly edged with white. The flowers of this are particularly symmetrical in shape. In all stages of growth this can be

*Lilium speciosum* on terrace. Engraved from a photograph sent by Mr. S. Hore, Hatt, R.S.O., Cornwall.

most instances it is more useful when it blooms at its usual time, forming as it does a link between many summer-flowering plants which are then on the wane and the first of the *Chrysanthemums*. In growing this Lily in pots a good deal will, of course, depend upon the purpose for which the plants are required, as in some cases, particularly if they have to be dropped into ornamental pots or vases as they come into bloom, the bulbs will often need to be potted singly; whereas for the embellishment of conservatories and such like several bulbs in a large pot yield the best results. A suitable compost for potting is good turfy loam, lightened somewhat by an admixture of leaf-mould and well-decayed manure, with a liberal sprinkling of sand. For single bulbs pots 5 inches in diameter (that is the regulation 48-sized pot of the market growers) will suffice, but for others pots 6 inches or even 7 inches across will be needed. Bulbs of *L. speciosum* are sent to this country in large numbers when dormant; hence, though it is important to pot them as soon as possible, it should be borne in mind that those from Holland do not, as a reach here till October is well advanced,

larger clumps can be formed by an increased size of pot and a greater number of bulbs. When out of doors during the summer no great amount of attention is needed, but the soil must not be allowed to get too dry at any time; while, on the other hand, an excess of moisture must be avoided. A good deal of trouble is saved by plunging them to the rim of the pot in cocoanut refuse. When out of doors insect pests rarely trouble this Lily, though occasionally a few aphides make their appearance; but under glass they are sometimes more numerous, and a black fly is also troublesome. When the pots get full of roots a mixture of weak liquid manure and soot water will be of service, as it tends not only to encourage the flower buds, but also to retain the foliage in good condition. When this Lily is grown in pots a good time to repot is soon after the flower-stems decay, for it will be found that the stout roots at the base of the bulb commence growing with great freedom soon after flowering is over. They may be shifted on into larger pots as needed, but where the pots are already large enough and the soil and basal roots in good condition, a top dressing is all that is required. To do this

picked out, for not only are the leaves very broad, but the stems, leaf-stalks and flower-buds are all of a deep chocolate tint. Single bulbs of this variety are more liable to produce two or three shoots than the others are. Though considerable numbers of *Melponene* come here from Japan, there is a second form which is even more numerous. This is usually disposed of under the varietal name of *rubrum*, and represents a form much superior to that sent to this country under the same name by the Dutch cultivators, added to which many of the Japanese bulbs are of enormous size. The confusion that exists in the nomenclature of these coloured varieties is to be accounted for to a certain extent by the fact that the different forms merge into each other by almost imperceptible gradations; hence it has been suggested to bestow the varietal name of *rubrum* upon that form in which the stems and outside of the buds are brownish, and classify those with green stems under the head of *roseum*. This is impossible, as many are about midway between the two, and in some instances the flowers borne by the dark-stemmed forms are paler than those of the green ones. The fasciated form of *rubrum* usually known as *monstruosum* is altogether a poor plant. A distinct variety is *punctatum*, less vigorous than the others, the flowers of which are white, dotted with pink. The blooms of this, especially when in the open ground, often fail to open in a satisfactory manner.

H. P.

**Wintering Caladiums.**—I quite agree with "W. J. M." (p. 522) as to a good amount of heat being essential to wintering Caladiums. I think, generally speaking, that there is a mistaken impression as to heat causing dry rot. During the past nine years I have wintered very successfully a good collection of the best varieties without a failure. I stand the pots containing the bulbs on a shelf in a plant stove, and, this being a lean-to, the position is very dry and warm. I believe that there are more failures from wintering in too low a temperature than from any other cause. No water is needed to keep the bulbs plump.—A. Young.

**Three good winter-blooming zonals.**—The best winter-blooming *Pelargonium* is undoubtedly the popular *Raspail* and its improved varieties. It blooms freely, and the colour is just what is needed in the depth of winter. Excellent companions to it are *Mme. Thibaut* and *Guillon Mangilli*. The former affords an excellent contrast in colour, is remarkably free-blooming, and is, indeed, one of the best all-round zonals we have. Well-grown plants in 6-inch pots will furnish a lot of bloom during winter and early spring. *Guillon Mangilli*, quite an old kind, suddenly came to the front a few years ago, but even now it hardly gets so much attention as it deserves. The flowers are very rich in colour, and the trusses come very large on strong specimens. This is the best zonal I have ever had to do with, as it will expand its blooms fairly well in the depth of winter, even in a cool house where no more fire heat is used than will exclude frost.—J. C. B.

**Rivina humilis.**—This *Rivina* is in no way remarkable for foliage or flower, but the little bright red berries which succeed the blossoms render it very attractive when in the fruiting stage. It is a slender growing subject, not at all difficult to cultivate, and may be either grown in pots or planted out. For convenience of grouping it is generally grown in pots, sometimes singly or at others three in a pot. If this latter method is followed, and pots 6 inches or 7 inches in diameter are employed, handsome little specimens may be obtained, and when laden with their drooping racemes of brightly coloured berries they are really charming. Planted out, this *Rivina* will acquire a rambling habit of growth, and soon

cover a considerable space. It is not a particularly vigorous rooting subject; hence a depth of soil of about a foot will be sufficient. Good drainage must be secured, and a compost consisting of equal parts of loam and leaf-mould, with a liberal amount of sand, will suit it well. During the summer this *Rivina* forms a pretty object in the greenhouse, but to be seen at its best during autumn and winter it needs the temperature of an intermediate house or the cool end of the stove. Seeds afford a ready means of increase, as young plants can be raised in quantity in this way. There are two or three kinds, a looser growing kind with yellow berries (*flava*) yielding a pleasing variety.—H. P.

#### WINTER-BLOOMING BEGONIAS.

THESE are charming for the warm conservatory. A group of *insignis* is very light and elegant, and the flowers are fairly lasting and far more effective than the fashionable tuberous varieties with the heavy cumbersome flowers. Size is not everything; lightness and grace will ultimately find their true place. Then these small-flowered *Begonias* are so easily grown. They make plenty of cuttings, which strike freely in heat in spring, and with fairly good warm frame culture till the end of June they may be grown in nice little specimens in 6-inch pots. If larger specimens are required, three plants in an 8-inch or 9-inch pot will produce them, or cut-down plants may be potted on a second year, but in a general way after the stock of cuttings has been secured, the old plants may be planted out in the borders. Those who have never tried these small-flowered *Begonias* in a sheltered place outside will wonder why they have been neglected so long. Give such kinds as *insignis* and the various forms of *semperlorens*, *nitida*, *Ingrami*, *fuchsoides*, *ascotensis*, and *Carrieri* a sheltered, well-drained site, and they will make charming masses in summer and early autumn; and if before frost comes they are lifted carefully, they may be useful in the warm conservatory during a good part of the winter. It is a good plan to strike the cuttings as early in February as possible, and not to crowd too many cuttings into a pot. Single cuttings in 2½-inch pots would be best, as then there is no disturbance of the roots. The little plants when well rooted are simply lifted out of the propagating bed, and when hardened a little are shifted on as they require more root room. By this means every facility is given to the bottom eyes to shoot out, and consequently the plants get well furnished at the bottom, which is not always the case when many cuttings are crowded into a pot. If the plants are intended for the open air, grow on till the end of May and then harden off and plant out in the second week in June. *B. weltoniensis* is a well-known cottage window plant, and it also makes a pretty group in the open air. This is a tuberous variety, though distinct in character from the large-flowered type. E. H.

#### LIBONIA FLORIBUNDA.

It is now over thirty years since this *Libonia* was introduced from Brazil, and soon after that time it became very popular indeed. I should think it was more generally grown twenty years ago than it is at the present day, though it certainly is not superseded by any newer introductions. Where a display of bloom (and that of as varied a nature as possible) has to be kept up throughout the winter, this *Libonia* readily lends itself for the purpose, for with attention it will bloom for months together, and that, too, during the dullest period of the year. To have plants for blooming in the winter different means are resorted to, for by some cultivators they are planted out as *Bouvardias* at times and lifted in the autumn. This treatment is, however, in a general way hardly to be recommended for the *Libonia*, as with the check of lifting, the foliage is apt to acquire a yellowish tinge, which it will frequently retain throughout the rest of the season. To ob-

tain good flowering specimens the stock plants intended for propagating from should, quite early in the year, be placed in the temperature of an intermediate house, and when the shoots then produced are long enough, they should be taken off as cuttings. The cuttings do not take long to root, and if the plants are grown on freely, using a mixture of loam, manure and leaf-mould, they will about the beginning of June be fit for shifting into pots 6 inches in diameter in which they are to flower. When established in these pots they are better outside, but care must be taken that they do not suffer from want of water, otherwise the foliage will soon get yellow. As the pots get full of roots additional stimulants, in the shape of liquid manure, will be of service, and weak soot water will also tend to keep the foliage in good condition. Grown in this way, plants of this *Libonia* will in a warm greenhouse be objects of beauty for a long time, their bright scarlet and yellow blossoms being very conspicuous among their associates. One frequently hears of many greenhouse flowering plants refusing to bloom in a satisfactory manner during the winter, most of which is, I think, owing to the elastic way in which the term "greenhouse" is applied, for by some the word "greenhouse" indicates a structure from which frost is just excluded and nothing more; whereas for flowering plants a gentle heat is at all times necessary, say a minimum temperature of 50°. A plant well worth growing with this *Libonia* is *Sericographis Ghiesbreghtiana*, now included in that comprehensive genus *Jacobinia*. The deep scarlet flowers of this *Sericographis* in conjunction with its dark green foliage form a very attractive feature. H. P.

**Anthuriums.**—Although not numerous at this season, the richly coloured blossoms of a few *Anthuriums* form a showy mid-winter feature in the stove, their value in this respect being still further enhanced by the length of time they remain fresh and bright. The most noticeable of all just now is a vivid coloured form of *A. Andreanum*, by no means of good habit. The various hybrids, in the production of which *A. Andreanum* has played a part, also flower more or less in the winter, and their paler tints afford a pleasing variety to the richly coloured flowers of *A. Andreanum*. The first of these hybrids to which attention was particularly directed is *A. ferriense*, raised between *A. Andreanum* and the white-flowered *A. ornatum*. Since then a very large number of varieties has been put into commerce, but many of them greatly resemble each other. *A. ferriense* has the flowers of a bright rosy carmine colour, while varieties with salmon-coloured spathes are also represented among these numerous hybrids. The stout leathery leaves of these hybrids of the *A. ferriense* type render them very ornamental from a foliage point of view alone. Raising seedlings of these *Anthuriums* is very easily carried out, and is a source of considerable interest. *A. Scherzerianum*, too, must be recognised at this season, for though there is at present not a great wealth of blossoms, yet their bright colour renders them very conspicuous.—T.

**Wintering Cannas.**—Some of the newer race of *Cannas*, more particularly those with yellow blossoms dotted with red, do not produce very stout rhizomes, and if kept too dry during the winter they are very apt to perish. Within the last few years large quantities of *Cannas* have been distributed by our nurserymen during the winter months, as when dormant they can be readily sent through the post. On receipt they should be at once potted and placed under conditions favourable to growth, for if the rhizomes are bruised or injured in any way they are very apt to decay if kept out of the soil, but when potted, roots are quickly produced and decay is at once arrested. Those that are established in pots will keep well in a greenhouse and with the soil in a slightly moist condition. With a little additional heat, however, *Cannas* may be had in flower nearly all the year round, and as an illustration of their early flower-

ing qualities it may be mentioned that the variety Alphonse Bouvier, which received an award of merit three years ago, was so honoured on January 12, so that the plants then shown could not have passed the winter in a dormant condition. Where it is intended to cut up a number of rhizomes for propagating, this is best carried out just previous to potting, as if done and the rhizomes allowed to remain out of the soil decay is very apt to set in, commencing from the cut portion. The first roots and the most vigorous ones are produced from the upper part of the rhizome just below the spot from whence the leaves are pushed forth.—H. P.

ABUTILONS.

THERE are many varieties of Abutilon with yellow blossoms, but of all of them I prefer Golden Queen, a free-growing, free-blooming variety with rather long flowers of a beautiful golden yellow. It is a first-rate subject for winter blooming, for where flowers have to be supplied at all seasons some of the Abutilons are well-nigh indispensable. As this variety is one of the best in its colour, so the old white Boule de Neige still stands out as unsurpassed among flowers of that tint. Boule de Neige has been grown in our gardens for many years, but I am unacquainted with its origin or early history. By the intercrossing of this variety and the brick-red Darwini, the numerous forms that we have now in cultivation originated. Of reds there are many varieties, and Royal Scarlet, Firefly, and Scarlet Gem are all good. Among those of a pink, rose, or light purple shade, such as King of Roses, Anna Crozy, and The Premier may be mentioned; while among striped flowers we have Abutilon striatum and the large bold-growing A. venosum. A few years ago two very dwarf varieties were put into commerce, but they were never much grown. They were roseum compactum and Vivid compactum, both in their way very pretty. Of variegated-foliaged forms there are several, some of which are largely used for bedding out during the summer. Chief among these are Thompsoni, whose leaves are mottled with a creamy tint; Darwini tessellatum, with yellow variegation, the arrangement of which is well expressed by the varietal name of tessellatum; navium marmoratum, a free-growing form whose leaves are marbled with cream and light green; Souvenir du Bonn, deeply lobed leaves after the manner of A. striatum. They are all broadly margined with white. Another newer form which is of Continental origin is a good deal in the way of the last-named, but the edging of white, or rather creamy white, is very much deeper; so much so, indeed, that in many of the leaves the central green portion is but a small part of the leaf. The slender rambling growing A. vexillarium is also represented by a variegated-leaved variety, but when growing strongly this is very liable to revert to the ordinary green-leaved form. The last to mention of these variegated Abutilons is A. Sellowianum variegatum, whose large, almost horizontally disposed leaves are marked with a couple of tints of green and pale yellow in varying proportions. One double-flowered form is in cultivation, viz., A. Thompsoni flore-pleno, but it is to my mind less pleasing than the single-flowered forms; still it is by some grown for the sake of variety. Given a warm greenhouse during the winter, flowers of Abutilons may be had nearly throughout the year, for in the summer young plants in pots 5 inches or 6 inches in diameter will flower freely, while older specimens if planted in the open ground will bloom for a lengthened period. As wall or pillar plants many of the Abutilons are very suitable, the more vigorous forms, such as A. venosum, being best for lofty structures, while most of the garden varieties will furnish pillars or walls of medium height. A vexillarium, whose small brightly-coloured blossoms are supported in a drooping manner by long footstalks, displays its prominent characteristics when trained to a conservatory or greenhouse roof, and out of doors at Kew this species has, strange to say, passed through

several winters on a low wall in front of one of the stoves.

All the species and varieties of Abutilon are readily propagated by means of cuttings, which strike root very quickly, but where time and space are at disposal, the raising of seedlings is an interesting occupation, for they all hybridise readily, and some very curious forms may be obtained. The distinct A. insigne, with its striking crimson blossoms, might (in conjunction with the garden varieties and some of the most distinct species) yield very interesting results. T.

ORCHARD AND FRUIT GARDEN,

SWEET CHERRIES.

FULLY grown, perfectly ripened, sweet or dessert Cherries are, comparatively speaking, a rarity. Morello Cherries are plentiful enough in their season, and what is the reason the sweeter varieties are not equally so? The reply, if given generally, would in most cases be because the birds prevent any from being profitably grown in the open in all but well-tended orchards,

The Black Heart Cherry. Engraved for THE GARDEN from a photograph by Mr. Norman Blake, Bedford.

while the amount of fish-netting necessary for protecting fruit on the wall trees renders their culture more expensive than desirable. Where wall space is somewhat limited, I can understand why sweet Cherries find no place, or are only grown in very limited numbers, but in the larger gardens neither this excuse nor that of undue expense holds good. Those few who do succeed well with choice Cherries do not make the very common mistake of sticking in a tree here and there among Plum, Peach, and other trees, but devote a good length of wall wholly to them. In very hot and dry positions the trees are particularly liable to be overrun by black aphid, while the fruit fails to attain its full size and richness of flavour during dry, hot seasons, and the sunniest walls are, therefore, more profitably devoted to Peaches, Nectarines, and Apricots. Walls facing in either easterly or westerly directions are most to be preferred, and if any are grown against colder walls or with the Morellos, the fruit produced will be more remarkable for lateness and acidity than for any good quality. The May Duke, which I suppose must be included among sweet Cherries,

is, perhaps, an exception to the latter rule, very acceptable crops being had from trees against cool walls. Instead of dotting a few Cherry trees among other kinds of fruit trees, group them at one end, or, if it can be afforded, let them have a short length of wall, this in either case admitting of their being effectively netted, as they must be, directly colouring of fruit commences, or the birds will soon clear the trees. As before hinted, it is next to useless to plant a few single trees in the open, especially where blackbirds and starlings abound, unless they can be netted over, a by no means difficult undertaking when pyramids or bushes are planted in rows alongside walks. The bulk, or probably the whole of the fruit sent to the markets is grown on standards in orchards, and principally in Kent and Hertfordshire. Some seasons they pay remarkably well, but the fruit is very liable to crack wholesale on the trees, so that Cherry growing must be regarded as a lottery. In each and every case the finest trees and best produce are to be seen on the deep calcareous, loamy soils and in moderately high positions. If, therefore, these conditions are observed in private gardens generally, to the extent even of largely substituting fresh strong loam with mortar rubbish and sharp sand or road grit freely mixed with it for the ordinary garden soil, there is no good reason why failures should occur.

The choice of suitable varieties is not so limited as might appear to anyone who took particular note of what are grown in the various gardens in which Cherry trees find a place. Authorities divide them into sections or races. Thus there are Geans red and black, Black Hearts and Red Hearts, or Bigarreus, and Griottes black and red. The Geans are rigid and spreading in habit, and have long thin leaves, while the fruit is obtuse, heart-shaped. Of the black varieties, Black Eagle and Early Rivers are perhaps the best, Frogmore Early being preferred of the red fruited forms. The Heart or heart-shaped section comprises several very excellent and popular varieties. The trees are of much the same habit of growth as the Geans, and a good selection would consist of Black Tartarian, Late Black, Elton, Bigarreau Napoleon, and Governor Wood, with Florence for a late crop of fine, if not particularly richly-flavoured fruit. The Griottes comprise the popular May Duke and Late Duke, Reine Hortense being also a worthy member of the same family. The trees in these cases are of stiff, upright habit of growth and have large and broad leaves, while the crop is usually very heavy. From the foregoing the following six might be selected, and are given in their order of ripening: Early Rivers, Governor Wood, Black Tartarian (Bedford Prolific, a good substitute), May Duke, Bigarreau Napoleon, and Florence.

For walls, fan-shaped trees are most to be preferred, though stiff-growing Cherries succeed well under either horizontal training or a modification of the two systems, fan-shaped trees having their branches gradually brought to a horizontal position. The stronger growing varieties, or the Hearts and Bigarreus, should be allowed good room to grow, much-restricted trees forming far too much breast-wood to be productive. These, then, should be planted not less than 24 feet apart, and if the walls are 12 feet and upwards in height, so much the better. May Duke and varieties of similar habit of growth may be planted 18 feet apart. Cordons, though sometimes recommended, require to be frequently root-pruned in order to check exuberant growth, and they then succeed fairly well. These, if single, ought to be worked on the

dwarfing or Mahaleb stock, and if single branched be planted 18 inches apart, two or three branched trees having a width of 15 inches to 18 inches allowed for each branch. These may be trained either vertically or obliquely, the latter method giving the greatest length of branch and the lower parts of the tree get a greater share of the sap than is the case with the upright trees. Horizontally or espalier-trained trees are not often seen in the open, but they succeed well trained in that way and can be readily netted over. Very handsome pyramids as well as bushes can be formed, and these often crop surprisingly well. For these, again, the Mahaleb stock is to be preferred, and the distances apart may vary from 9 feet for the May Duke family and 12 feet for the stronger growers generally.

A certain amount of rather hard pruning will always be necessary for a time, or till a good foundation is laid, but afterwards the leading shoots should be reserved to their full length. The more they are pruned the more strong wood growth is formed; whereas shoots left to their entire length will flower sparingly perhaps the next season and be wreathed in flower the second spring following, a cluster of fruit-buds invariably forming at the same joints in after years. All superfluous summer growths ought to be early stopped at the fifth or sixth joint and the break from these at the first joint. Then if shortened to 1 inch in length at the winter pruning the fruit-buds at the base will open strongly and be followed by clusters of fruit, the foundation of what may be termed a good permanent fruiting spur being laid. When this method of pruning does not answer well, owing, it may be, to the trees not having sufficient head-room, they ought to be treated similarly to Morellos or Peaches, a moderate number of young shoots being laid in during the summer and reserved to their full length at the winter pruning, all flowering with moderate freedom the following summer. This necessitates cutting out each winter much of the wood that has only fruited once, while root-pruning should be frequently practised when necessary to check a too vigorous growth.

Cherries very rarely escape an attack of black aphid, but early summer pruning or stopping, followed by forcible syringings with first a decoction of soft soap and quassia chips and then clear water, will usually get rid of this pest. Without being particularly tender, Cherry blossom is yet frequently damaged by frosts; hence the wisdom of covering or protecting with doubled fish-nets hung loosely over them. Thus treated nearly every flower is followed by a fruit, and in many cases the set of fruit is heavier than should be left to ripen. Thinned out with moderate freedom, all those reserved will attain their full size and be richly flavoured, but when all are left hanging some will fail to ripen and the rest be of poor quality. Cherries should be fully ripe before they are gathered—that is, if their full flavour and richness are desired. It is true keeping them thus long may mean the loss of a considerable number from cracking, this taking place in showery weather or when the atmosphere is highly charged with moisture. Both May Duke and Black Tartarian hang well after they are ripe, and a good dish of the latter has great weight in a collection of fruit in August.

Cherries can be grown remarkably well under glass, and bushes, either planted out or in pots, present a most attractive appearance when the fruit is ripe. The wonder is so few houses have been put up for them. Hard forcing should not be attempted, but they could yet be had by gentle forcing ready for use late in April, a good selection of varieties keeping up the supply till

late in June. If kept in pots the house could be cleared in time for a good late crop of Tomatoes to be had, the rest for the trees outside being most desirable. W. I.

**Peach Dymond.**—I can fully corroborate what "G. W. S." says at page 482 respecting this fine Peach. It has not only size, colour and flavour to recommend it, but a very hardy, free-bearing constitution. It is a good open-air Peach and does well in that position in this garden, ripening in good time in August. It keeps longer after being gathered than many sorts and travels well. It may not be generally known that Dymond is a capital forer, ripening as soon as Stirling Castle, and no doubt would succeed equally as well in later houses. Mr. Coleman, of Eastnor, once told me that if he were confined to one Peach and one Nectarine for tub work he would choose Dymond and Stanwick Elruge.—J. CRAWFORD.

—This Peach is recommended at page 539 by "W. G. C." for early forcing. I have had it in quantity early in June, and this season I hope to have it quite a month earlier. It is a very valuable Peach either indoors or on walls. Even this last summer I gathered fine fruits at the end of August from young trees planted the previous November. I do not know of a freer growing variety, and when forced it sets very freely. The summer of 1893 was a grand one for Peaches, and I find I gathered Dymond on August 10 from open walls without protection of any kind.—W. S.

**Flavour in Pears.**—With me Doyenné du Comice from pyramid trees was much richer in flavour than the larger fruits from cordons, but these latter were allowed to hang longer before being gathered so as to lengthen the supply. I attribute the difference to the extra time of hanging, as I know by experience that mid-season Pears are depreciated in quality if left hanging too long. This is especially noticeable with Louise Bonne de Jersey and also the earlier Beurré d'Amanlis. Some varieties of Pears are very much influenced by soil and situation. The best Duchesse d'Angoulême that I ever tasted was gathered from a tree growing at Conway, in North Wales. The finest flavoured Beurré Superfin I have tasted this season came from the late Dr. Roden's garden at Kidderminster.—Y. A. H.

**Peach Crimson Galande.**—I was pleased to see "W. G. C.'s" remarks on this Peach at p. 535, as I have found it excellent in every way and very useful for forcing. This variety is well adapted for early work. Where very hard forcing is carried on I would prefer Early York, Early Grosse Mignonne, Hale's Early or similar varieties. I have found Crimson Galande most serviceable for dessert from about the middle of June. The flavour is good and the fruits when well fed attain a large size and are beautifully coloured. Being a freestone adds to its other good qualities. The growth is vigorous, and it does grandly on a warm soil in the open. The flowers are small, but they set freely. My experience with this variety when hard forced is that it requires more air when in bloom than some of the kinds. This may not generally be the case with trees in modern houses.—S. H. B.

**Apples in poor soil.**—With regard to dessert kinds I have found King of the Pippins rarely fail in any soil or locality, and though by some growers it is considered of second-rate quality, I do not class it as such, as, taking all points into consideration, it is excellent in every way, a great and certain cropper, and I have never known trees to fail in any soil or locality where they had a little care at the start. This variety I put at the top of my list of dessert kinds for poor soil. Kerry Pippin is another old variety that rarely fails to crop in any soil, and where early Apples are required it is valuable. The well-known Blenheim Orange is not fastidious as to soil when the tree has attained a fair age. I admit in a young state it is a shy bearer, but when older it fruits grandly as a standard and in most localities.

Yellow Ingestre is a great cropper and rarely fails. Baumann's Red Reinette is likewise good, though fruit very handsome and keeping well. Among the cooking varieties there is a wider selection. The Keswick Codlin rarely fails. To this should be added Manks Codlin and Lord Grosvenor. Cellini is a certain bearer in light soils, but not suitable for wet or clay land. Lane's Prince Albert is a grand Apple and not particular as to soil or locality. Lord Derby, Annie Elizabeth, Golden Noble and Waltham Abbey Seedling are all suited for light soils. Alfriston always does well, young trees producing very fine fruits, which keep well into the spring. The above is a select list of varieties that I have found to do well in poor soil with no special treatment.—G. WYTHES.

**New Apple Armorel.**—This is a valuable addition to the list of late dessert Apples. Armorel is a good variety to follow Cox's Orange Pippin. It may be had in good condition well into May. It is on account of its lateness that I send this note, as though we have Apples in great variety, we have only a few really good late dessert kinds at the time noted above. I saw this variety doing well in bush form last summer, very small trees cropping freely. It was raised by Mr. Ross, of Welford Park, who thinks it one of his best seedlings, and it has received the highest award of the Royal Horticultural Society.—G. W.

#### THE FUTURE OF HARDY FRUIT CULTURE.\*

IN face of the agricultural depression and the problem of how to make the land pay, we may take a glimpse of what the prospects of hardy fruit growing for profit are likely to be in the future. The Apple is acknowledged to be the king of British fruits, and has received more attention in consequence than any other kind. Plums and Pears are perhaps next to Apples in importance, but unless the soil and situation are very favourable, I would not plant Pears, as they are too uncertain and more liable to injury from climatic changes. My experience is that both Apples and Plums are far more profitable planted and grown under the same conditions. In bush fruits and Strawberries we find the acreage increasing rapidly, and probably the number of varieties of each kind will be reduced in the future, as there are only a few sorts of each that will give handsome returns. Take Gooseberries as a case in point. We are forced to rely on such varieties as Whinham's Industry and Keepsake for early picking. Immense quantities of trees have been planted of late years on a system that is neither the most profitable nor best. If we must compete successfully with the foreigner in the future we must alter our methods, not only in the form of trees, but also in the selection of varieties, grading, insect destroying, manuring, pruning, and last, but by no means least, given an equal chance with the foreigner in railway rates.

#### FORM OF TREES.

It is high time that fruit growers should abandon the standard and only plant dwarf trees, which can be pruned, sprayed with reliable insecticides, and the fruit gathered from the ground. Instead of waiting twelve or fourteen years a profitable crop may be reasonably looked for the second year after planting dwarf trees, and, being low, they are not exposed to gales, with their disastrous effects to the fruit, and the branches are not broken by ladders, as in standards. These are a few of the advantages of the dwarf form of tree, and when such are fully recognised by planters I believe it will be the tree of the future.

\* Paper read by Mr. S. T. Wright, Glewston Court Gardens, at the Hereford fruit conference, November 15, 1894.

## GRADING THE FRUIT.

Of all things connected with fruit culture, I question if anything reflects so much discredit on the home grower as the way in which our fruit is consigned to market. To prove this it is only necessary to visit any of our chief markets in the season and note the slovenly way in which Apples are placed in baskets or other packages. It is very seldom that any care is exercised in the grading; large and small are bundled together until the basket is nearly filled; it is then topped up with some of the finest fruit and put on the market. This is a grave scandal, as it is not honest, and is a deliberate attempt to deceive the purchaser, bringing general discredit on the English fruit grower. I had a strong proof of this in Edinburgh at the time of the International Horticultural Exhibition there in 1891: fruiterers there declined to buy English Apples because of what they justly termed "rascally packing." If we must meet the foreigner on equal terms in our markets, it is essential that we grade and pack our fruit as well, if not better than he does, and until this is done he will always have a large share in our business. At nearly all these fruit conferences great stress is laid upon the point of improved modes of packing, but so far little good appears to have resulted from the advice given. The comparatively few who do pack their Apples, &c., well can testify in emphatic terms how much they gain by their care and honesty. Every grower of fruit in bulk acquires a reputation in the market, and what that reputation depends entirely upon the man himself.

## INSECT DESTRUCTION.

As a body we are miles, as it were, behind our American and Canadian cousins in dealing with insect foes, and if we are to hold our own in the future, increased vigilance and attention to this matter will be a necessity. If the Hop growers of this country were to neglect the spraying and washing processes requisite to keep the plants clean, in the majority of instances the Hops would be conspicuous by their absence, and if this is true about Hops, it is equally important about fruit trees. Unfortunately, I have had some extremely disagreeable experience with insect foes, having had the trees under my charge bare of leaves and fruit in June through their ravages, but, thanks to the improvement in insecticides and the increase in knowledge of how to combat the enemies, we can keep them somewhat under control. In this dealing with insect pests we want a more united action amongst fruit growers whose fruit plantations adjoin each other; each one should do his utmost to spare none. If this were done throughout the country, future prospects would be much brighter and a vast amount of labour and anxiety done away with. At present if one man destroys all the caterpillars, aphids, &c., that may infest his trees, his next neighbour does nothing, thus providing a fresh stock for the industrious grower to fight against, and forcing him to battle annually to preserve his crops.

## MANURING.

Already great strides have been taken in our knowledge of chemical manures, and there is not the least doubt that the fruit grower in the near future will be able to do infinitely more by their aid than is possible at present. Soils vary so much in character, that what may prove of the highest service at one place may be practically useless at another. On light land we find potash lacking, and as this enters largely into most fruits, an application of potash in some form or other exercises a marked beneficial influence.

On heavy soils I think bone-meal has no equal, as it lasts some time in the soil, promoting a short sturdy growth and giving extra size and finish to the fruit. There are several first-class artificial manures, more or less suited to all soils, but which can only be determined by actual experience and a knowledge of the soil. While advocating the judicious employment of reliable chemical manures, we must not lose sight of natural manures close to our hands. One of the most valuable fertilisers from the farmyard is in the majority of places almost totally neglected, viz., the liquid drainings from cattle sheds and manure heaps; this is more powerful and immediate in its action than solid manures, and has a wonderful effect on the vigour of the trees and the size of the fruit, yet we see it treated as a nuisance on every hand. The object apparently is to get it away from the premises in as expeditious a manner as possible by way of ditches, brooks, or other available means. This ought not to be, and we may hope that such a cheap stimulant may be employed in our orchards to a much greater extent than now. Sewage, again, if put amongst the trees in winter would improve the appearance of the orchards, and pay over and over again for the labour incurred by the enhanced value of the fruit.

## PRUNING.

On this point opinions differ to a great extent, but the object of all is to get the greatest quantity of fruit of the largest size. In the past the knife has been used too much as a mutilator rather than as a pruner, the consequence being that more wood than fruit has been in evidence. Experience has proved that the knife should be employed only to remove weak and useless wood and to thin out the shoots, that each one may have sufficient light to ripen and properly mature its buds, leaving those that remain nearly their full length where possible, and, unless the seasons are very unfavourable, excellent crops will be the result. All old systems die hard, but I think in the future much less pruning will be done and heavier crops produced.

## RAILWAY RATES.

So long as the foreigner has the preferential rates for his fruit, the home grower will be seriously handicapped. I think nothing is more absurd than the fact that British capital has been spent in making our railways, and yet the Britisher has to play second fiddle to the foreigner, who has done nothing towards the making of the lines, &c. I question if any other body of traders would be allowed to tax the public so severely as the various railway companies do the home producer by their heavier charges. I do not intend going into figures to show the difference in favour of the foreigner, but I may state that in some cases the Englishman has to pay over 200 per cent. more for the same class of goods when carried the same distance. Is this fair? While kicking against these excessive charges, we do not want the railway companies to carry our goods at a loss, but only require them to put us on an equal footing with our rivals. On those conditions I feel sure that the British fruit grower will be able to hold his own against any competition from all parts of the world, provided the business is conducted with vigour and on sound principles.

**Apple Bismarck.**—“W. G. C.” (p. 481) asks for information as to the behaviour of Bismarck Apple in different localities, and also mentions that some growers give it a bad character on account of its proneness to canker with them. I have just looked over about 150 Bismarcks on the

English Paradise stock, two, three, and four years old from the graft, and have found no sign of canker on them, though other varieties of the same age are cankering rather badly. Three years ago I planted as an experiment thirteen four-year-old Apples on the Paradise. The ground is heavy, but the trees have lacked no attention since their planting, at which time they were clean, well-grown bushes. Pott's Seedling is nearly dead from canker, which has attacked every branch, and King of Tompkins County is in almost as bad a plight. Cox's Pomona, Cox's Orange, Stirling Castle, and Lady Sudeley have all cankered, but have made good growth this year notwithstanding, and have also fruited well. Lane's Prince Albert and Blenheim Orange show symptoms of the disease, while Bismarck, Peasgood's Nonsuch, Warner's King, Bramley's Seedling and Duchess of Oldenburg are all healthy, the last being in the pink of condition and as near perfection as possible. As far as my experience goes, therefore, it would appear that Bismarck, at all events in this district, is not so subject to canker as many other varieties. It has seemed to me that Apples on the Paradise are more liable to canker than those on the Crab stock, but I am told by a large grower that his experience has been that the reverse is the case.—S. W. F., *Torquay*.

**Grapes cracking.**—“J. C. B.” (p. 495) says “growers of Grapes do not seem to be quite agreed as to the cause of cracking.” The experience of “J. C. B.” as to dryness of the soil in his case is, I have not the least doubt, perfectly correct, although I must confess it is the first case I ever heard of Alicante being addicted to cracking, but the over-dryness explains it. The variety with which I ever had any trouble is Madresfield Court, but not of late years, as I have proved that cracking may be caused by sudden fluctuations of temperature, which I now prevent. My experience with this Grape is, that when the berries commence their second swelling and also commence colouring, if the ventilators are closed so early in the afternoon as to cause a sudden rise of the temperature, or kept too close in the morning before the ventilation is increased, cracking will take place. I am also of the opinion that if the berries are not thinned sufficiently, cracking is further aggravated. Under high culture the berries swell up enormously, but if this is anticipated at thinning time, cracking from this cause will be prevented. As a rule, I do not think the berries of this Grape are thinned out nearly enough. With a little warmth continually in the pipes—a limit, of course, being allowed during the hottest part of the day—with a free circulation of air, cracking will be prevented.—A. YOUNG.

## THE REPLANTING OF WALL TREES.

As the theory and practice of root culture become better understood it is probable that most fruit trees—on walls at least—will be planted a second time, about a year after the first. This is likely to keep the roots in the best place for the production of fruit-buds and also to mould them into the best form. The form of wall trees and the limited areas of their tops in contrast with those of standards, bushes and pyramids render their replanting or root-pruning more important. The chief dangers of young wall trees in favourable soils arise from over-luxuriance. This has been fostered from their youth up by concentration of force alike in root and top. The latter favours the rushing up of trees to saleable condition. Now one stopping of roots in the process of removal or planting does not suffice to eradicate the strong-growing habit. On the contrary, the first breaks on such roots will partake of the character of their immediate progenitors. The first roots after permanent planting often break away as strongly as those of the original maidens, and this natural excess of vigour at the roots is the parent of the sterile growths that crowd the tops of young wall trees with sappy wood that cannot possibly respond promptly with full crops of fruit of fine

quality. By carefully replanting trees a second time the roots will be led or gently forced into fruitful form.

Once trees are thoroughly established on these lines the annual crops of fruit mostly suffice to keep them on fruitful lines. However, another great advantage of a second planting is the establishment of what may be called with little or no exaggeration a semi-portable and intensely fertile character of root. Those possessing extensive experience in the raising and training of young trees are aware how tractable the roots are. After a few removals the trees are but little inconvenienced by root-lifting or replanting. Some cultivators go further, and assert that the trees thrive best through removal. Be that as it may, it is certain that such root-detachment and disturbance favour the highest possible degree of fertility.

D. T. F.

**The wild Medlar.**—Will any reader of THE GARDEN kindly tell me where I may procure plants of the wild Medlar or seedling plants of any kind of Medlar? I should also like much to know something about the distribution and habit of the Medlar in our country.—R. R.

**Peach Dr. Hogg.**—I note that "W. G. C." (p. 535) has a good word to say for this variety as being excellent for early forcing. I have not tried it for early forcing, but during the past nine years it has with me proved admirable in every way on the open wall. It is a very free setter, of good appearance, and most excellent flavour. I find it a reliable variety for open-air culture, and am glad to hear that it is equally so for early forcing.—Y. A. H.

**Apple Cox's Orange Pippin.**—It is unfortunate that this Apple will not succeed on all soils, and I think anyone who has had any experience of it will agree with "E. H." that it will not thrive on a damp, adhesive soil. The ideal soil for this Apple is a deep fertile loam with a dry sub-soil, and if not so naturally it should be made so by draining. When I first came here I planted a quantity, but the ground, I find, is too cold. I have replanted the trees on raised stations, hoping that by this method they will succeed. In selecting Apples for special soils it is very often not a question of what we should like, but what will succeed.—Y. A. H.

#### KEEPING FRUIT TREES APART FROM VEGETABLES.

THE short extract in the last volume of THE GARDEN (p. 535) on the desirability of keeping vegetables apart from fruit trees I entirely agree with. In many cases unfruitfulness amongst fruit trees can be distinctly traced to the system of cultivating the two in too close proximity to each other. Want of space is often given as the cause of this dual culture, but it is rather the outcome of an old custom. It is not even picturesque, for a garden with the trees scattered all about the vegetable quarters as well as along the walks has a very untidy appearance. The vegetables, again, are deprived of that very essential element to high culture, *i.e.* direct sunlight. Winter vegetables become drawn and are quite unable to bear the strain of a prolonged frost, and it is in those crowded gardens that such wholesale destruction takes place. Neither is it economical, for if ordinary care is taken when planning a garden to keep the fruit trees and bushes apart from vegetables, there will not be any space wasted, and each may have the culture which is necessary to ensure both good fruit and vegetables.

One of the greatest mistakes in fruit culture—that is if the most successful results are expected—is to deeply fork or dig over the ground within radius of the roots. A loose surface soil in itself is injurious enough, as fresh roots do not take readily to it; but the forking over destroys the surface roots and drives the lower roots downwards into what is very often a crude sub-soil. On a heavy clay land I have to be most careful in this respect, as the nearer the roots are to

the surface the better, so that they may receive the full benefit of sun heat. I have a long row of bush Cherries, and since they were planted, upwards of nine years ago, the surface soil has not been disturbed, and a forkful of soil within a radius of 10 feet could not be turned up without tearing up roots. These trees fruit abundantly and are never subject to gumming. In the case of bush Apples and Pears the soil only needs to be just pointed over, the manure, if this should be stable or farmyard, being just covered. I daresay the unfruitfulness of so many wall trees as seen now-a-days is due to digging too near the wall. The space left should be quite 5 feet or 6 feet wide, and the borders containing the roots of trees growing against north walls are best left intact if the space can possibly be spared. Y. A. H.

## GARDEN FLORA.

### PLATE 996.

#### ALTHÆAS.

(WITH A COLOURED PLATE OF *A. FICIFOLIA*.\*)

IN a comparatively recent monograph of the natural order Malvaceæ, Mr. E. G. Baker, of the

*Althæa officinalis.*

British Museum, enumerates over thirty species of Althæa. A small proportion only of these—perhaps some eight or ten species—are known in cultivation, and these are mostly confined to purely botanical collections. Were it not that the genus includes the plant from which the garden Hollyhock has sprung—*Althæa rosea*—it would be, so far as the majority of gardens are

\* Drawn for THE GARDEN in the Royal Gardens, Kew, by H. G. Moon. Lithographed and printed by Guillaume Severens.

concerned, an obscure and neglected genus. The Althæas are widely spread over Europe and Asia, and one species has been in cultivation that is found in the Caribbean Islands, two occur in Britain, and others have been introduced from Siberia and Northern India. The genus is, however, most abundantly represented in the region of the Grecian Archipelago and Asia Minor. The Althæas are nearly related to the Malvas, the chief botanical distinction being in the structure of the calyx. They are all herbaceous, some having annual or biennial, others perennial rootstocks. The Hollyhock may, in habit, be taken as characteristic of the genus, the stems being erect, varying in different species from 1 foot to 10 feet in height and furnished with large, usually palmate leaves. That the genus, as a whole, is not so much in favour with horticulturists as its merits entitle it to be is, I think, forcibly illustrated by the coloured plate published herewith, for *Althæa ficifolia*, although it has been in cultivation in this country close upon 300 years, shares to a considerable extent the general neglect of the Althæas. The larger proportion of the genus, however (or even of the species now in cultivation) cannot be said to be as worthy of so prominent a place in the garden as *A. ficifolia*. At the same time they are admirable subjects for planting at the back of wide borders and in open spaces in the semi-wild, partially wooded tracts of ground that so frequently surround gardens. In such positions naturally disposed groups if given fairly good soil and allowed sufficient space between the trees to admit sunlight, make striking features with their tall flower-stems, bright colours and large leaves. That there are few things which respond more readily to the gardener's art than these plants do is shown by what has been done in developing the Hollyhock from the wild *A. rosea*, and now that the disease has practically swept away the magnificent varieties which twenty or thirty years ago were the pride of hundreds of gardens—cottage and mansion—it might be worth while to take in hand and improve the best of the wild types of Althæa.

The perennial kinds can be propagated by dividing the plants or by seeds; the annual and biennial ones, of course, by seeds alone. It is best to sow the seed in February in pans kept in an unheated frame, planting the seedlings when large enough where they are required to be grown. If the weather does not prove showery after planting, the plants should be watered a few times, after which they will require but little attention.

*A. FICIFOLIA* (the Fig-leaved or Antwerp Hollyhock).—This species, perhaps the finest of all the Althæas, is nearly allied to *A. rosea*. In the opinion of Dr. Stapf, of the Kew Herbarium, who has lived and studied for a long time in the East, it may have been derived from it by cultivation. It is a plant which varies considerably, the height ranging from 2 feet to 5 feet and the colour from purple to yellow. It is, however, as a yellow or orange-coloured species that we know it in this country. The plant here depicted is a very fine form, which flowered in the herbaceous ground at Kew last July. It was from 4 feet to 5 feet high and bore a large terminal spike of flowers, each flower measuring 3 inches to 4 inches in diameter and being of a pale yellow colour, flushed with rose. The leaves are large, palmate, five to seven-lobed, differing chiefly from those of *A. rosea* in their narrow lobing. *A. ficifolia* is worthy of a place in the most select of herbaceous borders. Its native country is not certainly known. It is often given as Siberia, but Dr. Stapf thinks the species originated most probably in North-west Persia. *A. ficifolia* was known under cultivation as far back as 1597. The variety *glabrata* is a smaller form.

**A. ROSEA.**—This, the type or parent form of our cultivated Hollyhoeks, is said to have been originally introduced to this country from China in 1753. Whether it is truly a native of that country is perhaps doubtful; at any rate we know that it is abundant in Greece and other parts of the Mediterranean region. It grows to a height of 8 feet, the stem being furnished with large, cordate, five to seven-lobed leaves. The flowers are

rate of the former glory of the Hollyhoek restored.

**A. OFFICINALIS** (the Marsh Mallow).—This is one of our two British species, and is more especially common near the sea and salt marshes. Favourite districts are the fen lands of Lincolnshire and Cambridgeshire, on the banks of the artificial ditches and canals by which the flat lands of these counties are intersected. It attains a height of 2 feet to 4 feet, and has soft velvety leaves covered with a grey pubescence, and flowers of a delicate pink hue measuring  $1\frac{1}{2}$  inches to 2 inches across. In the old herbals it is accredited with many medicinal virtues. It is a perennial plant.

**A. HIRSUTA** is the other British species, and is found wild in the woods and fields of North Somerset. Its slender erect stems are 6 inches to 18 inches high; its leaves are reniform with long petioles, and its flowers are rosy purple and 1 inch in diameter. It is an annual. Some doubt has been expressed as to whether it is a truly indigenous plant, but if not, it has been naturalised for a sufficiently lengthy period to have become to all intents a British plant.

**A. CANNABINA.**—This species is a native of Southern France and Spain, spreading eastwards to Persia. It is a perennial, and is 6 feet high, having large palmate leaves with narrow lobes and coarsely toothed margins. The flowers are rose coloured.

**A. CARIBBEA** is, as its name implies, a native of the Caribbee Islands, having been introduced from there in 1816. Its flowers are produced on very short stalks, and are rose coloured with yellow centres. Whether it is now in cultivation is doubtful. It was figured in the *Botanical Magazine*, t. 1916, and is probably not hardy.

**A. NARBONENSIS** grows from 3 feet to 6 feet high and has pubescent, three to seven lobed leaves, the lobes being crenulated. The flowers are from 1 inch to 2 inches in diameter and of a pale purple colour. It is a native of France.

The nomenclature of these Altheas is very much involved, many of the species being subject to great variation and running one into the other by intermediate gradations. The following may be briefly mentioned as being either now or a short time ago in cultivation: *A. Froloviana*, a useful species flowering from August to October, tall in habit, and having orange-coloured flowers shaded with red; *A. lavateraefolia*, a native of Syria, with flowers near those of *A. narbonensis*, but of a deeper purple colour; *A. Hildebrandti*, 5 feet high, with white flowers, changing to pale yellow near the centre, and measuring 3 inches across; *A. striata* is another white-flowered kind; *A. flexuosa* is a North Indian species, probably tender, growing 2 feet to 3 feet high, and having large deep red flowers. The Syrian Hibiscus (*H. syriacus*), a shrubby plant, of which many single and double varieties are in gardens, is very frequently grown as *Althea frutex*. B.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**EARLIEST PEACHES.**—The American varieties grown either in a separate compartment or isolated amongst other sorts and started in the middle of November will by this time be expanding their blooms, those of Amsden June, where grown, being fully open. This stage being reached, both the night and day temperatures must be increased somewhat, whether the weather is frosty or not, as Peaches in bloom at this season are favoured with few natural advantages, and the deficiency must be made up by artificial means. During absence of frost a night figure of 55° may be allowed, but if on cold nights the mercury falls to 53 by morning, no harm will result provided the house is not too moist and the trees not trained

too near the glass. A most important point with these early Peaches is fertilisation, which must be carried out daily, advantage being taken of gleams of sunshine to admit just a little air and secure a dry pollen by midday. Different growers employ different mediums for dispersing the pollen, the camel's-hair brush and rabbit's tail both finding favour; but if the trees are in good health and the fertilising organs strong, nothing supersedes the old-fashioned plan of moving a straw hat to and fro immediately beneath the trellis. Where there is a superabundance of bloom buds, most of those located on the underside of the trellis may be removed before expanding by drawing the band in a downward direction. Any malformed blooms should likewise be removed. The oft-advised plan of fumigating the house as soon as the first pink petal appears must in no case be neglected, or green-fly may be found to have gained a footing at a time when insecticides must not be employed and curled leaves and fallen blossom be the inevitable penalty. If the trees were watered on the near approach of the blooms opening, no more will be needed until the fruit is set, but where the trees are growing in tubs or cramped and shallow borders, a further supply of moisture must be given. Injury to the blooms from surface moisture may be avoided by simply applying half an inch of perfectly dry soil, the same being removed in due time. Husband all sun heat possible by closing the ventilators early, and bear in mind that the most fatal error in Peach forcing is attempting to hurry on the crop before the fruit has stoned. Where the earliest forced Peaches are grown in pots, these of

The double-flowered Hollyhoek (*Althea rosea fl. pl.*)

rose colour 1, measure 3 inches to 4 inches across, the pale yellow centre being often surrounded by a black-purple ring. It commences to blossom in June and continues right into autumn. This description, of course, applies only to the typical form of the wild Hollyhoek, itself a most variable plant. From it have been raised by selection and hybridisation numerous and beautiful varieties more or less double, and ranging in colour from pure white to deep yellow or rich crimson. The palmy days of the fine Hollyhoeks, however, are for the present over, and the glorious colour effects they produced in gardens throughout the country twenty-five years ago are now only to be seen in places few and far between. This, as is well known, is due to the ravages of the Hollyhoek fungus (*Puccinia malvacearum*), which is believed to be a native of Chili. It first showed itself in Europe in the year 1869, and in 1873-4 spread over the Continent, and made a clean sweep of all the carefully raised varieties whose high cultivation no doubt had rendered them particularly favourable for the attacks of this fungoid parasite. As was the case with the Potato disease, its virulence, which at first carried all before it, has in late years somewhat abated, and it is possible that the future may see some at any

The single-flowered Hollyhoek (*Althea rosea*).

course must be watered from time to time even when in flower, but if this is always done early in the day, and as far as can be during sunshine, by opening the front lights half an inch a slight current of air is produced without actual draught and the surface soil of the pots speedily becomes dry.

**POT VINES.**—In many instances growth will now be 1 inch or more long, and the rods require

to be brought up into their final position and secured to the wires. Disbudding, now that the bunches can be well discerned, may also be done, selecting the most promising and removing the more feeble where this can be done without creating irregularities. Towards the lower portion of the rods, however, where weaker breaks abound, a greater percentage of growths may be left, the better to draw the sap to that point and strengthen and improve the bunches. No rigid law can be laid down for stopping, so much depending on the strength of the individual growths those at the top of the rods generally being best stopped at two joints beyond the bunch, weaker shoots lower down benefiting from a run of four or even five leaves. The stored-up sap will now soon become exhausted and the call for a further supply be responded to by the formation of new roots. The balls at this juncture need special attention, as dryness or wetness proves fatal to all further progress; the happy medium is the only safe condition. On bright warm days a dewing over with the syringe may be administered for some time longer, especially if cold nights necessitate hot pipes and a somewhat arid atmosphere at daybreak. Where blinds are used on the roof glass I would advise their use even for a few hours during daylight in times of sweeping gales and searing winds, especially in exposed situations. The trellises in early Vine pits and houses being generally none too far from the glass, it is a good plan to leave the ligatures sufficiently long to allow of the reeds falling a few inches below them; even this will permit of the laterals being secured to the wires. Continue the sprinkling of floors at intervals, according to the presence or absence of sun, and admit no air through January unless the mercury runs up beyond 75°. Prunings of old Vines wanted for bottle grafting later on should be duly labelled and inserted into pots of soil, storing them away in a cold greenhouse or orchard house. Vine eyes may now be inserted either in small pots or pieces of turf covered with river or silver sand, and placed in a cold frame to callus by the time they are placed in heat in February. Vines in pots intended for inarching may now be removed to the early house and placed on slates over the hot-water pipes.

**PLANTING FILBERTS AND COBS.**—These are worthy more care and attention than are generally bestowed on them. An open site, soil of a fairly sustaining nature, and liberal mulchings in spring are not lost on the trees, liberal thinning, especially of the centres of the trees, resulting in far heavier crops than can be secured by the old thicket plan. The ground should be well trenched and plenty of manure worked in, firm treading also being necessary before planting the trees.

**DAMSONS.**—These are too often neglected, which is strange, considering how well they pay. Where practicable, avoid planting on exactly the same spot, but where this cannot be helped, a good cart-load at least of fresh holding loamy soil should be substituted for the old worn-out compost. Damsons do not object to partial shade, but the best crops are obtained where a maximum of sun and light reaches the trees. After planting, mulch, and, unless in exceptionally sheltered places, stake for the first season at least. No better or more profitable Damsons exist than the Farleigh Prolific and Old Shropshire. J. CRAWFORD.

#### KITCHEN GARDEN.

**FRENCH BEANS.**—There will be no fear of dwarf Beans sown at this date not podding freely if attention be paid to heat and moisture. A regular supply may be kept up by sowing every three weeks according to the demand. French Beans can often be grown in pots on shelves when space cannot otherwise be found. Now is a good time to make a start, as the Beans set more freely with longer days and more sun. To get the best results a light position, such as a shelf in a Cucumber house, will answer well. Good results are secured from small pots at this time of year. I find 6-inch

pots useful for the early lots, but much depends upon the space at command. Three plants in a 6-inch pot will give a fair crop, but if 8-inch or 9-inch pots are used, five or six plants will be sufficient. The old system of partially filling the pots with soil when sowing and top-dressing when the plants have attained a fair size I do not advise, as the surface roots have no time to lay hold of the new soil. The new soil holds the moisture longer than that full of roots, making it a difficult matter to water properly. Much better results are secured by filling the pots nearly full and giving supplies of food later on in a liquid state. If the pots can be given bottom-heat or placed over warm pipes germination is more rapid and a stronger plant secured, slow germination in damp soil being the cause of decay of seed. In no case should water be given till the plants push through the soil. Now is a good time to prepare a pit or warm frame for this crop. A good return is assured if a bottom-heat of 70° can be given. The soil should be placed in position, mixing some old Mushroom manure with it, and by the end of the month it will be in condition to plant. A depth of from 9 inches to 12 inches will be sufficient. I advise sowing the seed in 3-inch pots and planting out in preference to sowing in the bed. When planting make firm, and by keeping the plants clean two or three crops may be secured by top-dressing, stopping, and feeding. No Plus Ultra, Mohawk and Syon House are all reliable at this season for pot or frame culture.

**PLANTING POTATOES IN FRAMES AND POTS.**—If the sets have been prepared as previously advised, they will now be in condition for planting. The soil should be warm and not too moist, so that in planting, the sets may be made firm and the fibrous roots spread out as the work proceeds. I attach great importance to planting prepared sets, as if merely placed in holes in moist soil the roots are cramped and do not spread out well, with the result that only one or two tubers are made, with a mass of small or later ones of no use whatever. It is best to plant with a trowel, and if the soil is at all clayey or wet to place some finer material round the sets to assist the tender roots to lay hold of the soil. If planted with care out of boxes, with a mass of fibrous roots and the sprouts or tops 2 inches or 3 inches long, there will be no difficulty in getting good dishes in three months if there is no check of any kind. Give ample supplies of air in fine weather to prevent drawing, with occasional waterings of liquid manure as top growth increases. When placing the soil in frames for planting it is not wise to err in giving too little. Much the same remarks apply to the culture of Potatoes in pots.

**SEAKALE.**—This vegetable will now come in even more useful than earlier in the winter. The weather having been mild, there has been no lack of good vegetables, this to a great extent saving the forcing supplies. If the Seakale grown specially for forcing has not yet been all lifted there should be no further delay, as it often happens we get a sharp frost when least expected. By lifting, laying in soil, and covering with litter, it is easy to get at the crowns when required.

**ASPARAGUS.**—Another lot of roots should be lifted if a supply was wanted at a certain date. From good roots lifted and placed in a genial temperature a supply may be had in three weeks, as the roots will force more readily now than when I last advised forcing lifted roots. Much the same routine must be followed as advised earlier. If a pit heated with hot water can be spared, there is no difficulty in getting regular supplies. If the heating agency is stable manure, it is well to incorporate a liberal quantity of leaves with the manure to prevent a violent heat. A steady heat will produce finer heads and of good quality if a liberal amount of air is given in mild weather and plenty of light. I noted the importance of forcing permanent beds, and the best means to produce strong growths from the end of February or earlier. Now is a good time to commence forcing in the open, and to get the alleys or space between the beds cleared out to make room for the forcing material.

**RHUBARB.**—This will be in demand from this date, and if a good stock is grown there need be no break in the supply. I noted the importance of lifting a good quantity of roots in advance, merely covering them with litter to check growth. Such roots placed in heat now will come in several weeks in advance of those lifted from their growing quarters and placed in heat. In lifting good-sized roots it is well to bear in mind that future years have to be considered, and if small pieces with a crown are detached from the roots when lifting, these make nice material for planting in March if laid in. Many shifts can be resorted to in forcing Rhubarb, and, provided there is an absence of rank steam, good growths may be secured. Now is a good time to cover outside roots. Should proper forcing pots be out of the question, equally good results may be secured by using old barrels, boxes, crates or such like. In covering avoid getting a violent heat.

**FORCING VARIOUS ROOTS.**—There will be more demand for other roots, and one of the best is Chicory. I have for the last few years grown the Witloof. The above root forces so readily, that it is not necessary to place large quantities in the house at one time. The roots winter well if plunged in the open and covered with litter in severe weather. Swede Turnips placed in a dark cellar force very quickly, and the young tender growths form a nice vegetable. Herbs will now be in greater demand in a green state. Mint should be lifted and boxed or placed in beds in heat. Tarragon will require similar treatment. Chervil and Basil should be sown in boxes, watering carefully for a time. G. WYTHES.

#### BOOKS.

##### THE LIFE OF RICHARD OWEN.\*

ONE of the most interesting men of our own day is the subject of this memoir, and one of the greatest of scientific men. A thorough master of his own work, he was much more than most men of the day, remarkable for having a heart for other things, being deeply interested in literature as well as in science, nothing of interest to human beings failing to engage his attention. He was remarkable also for a wonderful power of clear and pleasant talk. Interesting as the book is in many ways as the work of a very young man who hardly saw his grandfather in his best days, it gives rarely any idea of Owen's charming power as a talker. He was not by any means one of those who do all the talking themselves, but he was a delightful and sympathetic listener to every suggestion, and in fact charming to meet at the breakfast table or anywhere else. For many years of his life he lived in that pretty little garden round Sheen Cottage, which we have had the pleasure often of speaking of in THE GARDEN in past years.

Richard Owen, younger son of Richard Owen formerly of Fulmer Place, Bucks, was born at Lancaster on July, 1804. On his grandmother's side he was descended from Richard Eskridge, High Sheriff of Bucks in 1741, and owner of Fulmer Place, in the same county. His mother was of French extraction. She came of a Huguenot family of the name of Parrin, who came over from Provence at the Revocation of the Edict of Nantes. A woman of great refinement and intelligence, she was also an accomplished musician, a talent which she inherited from her father, a professor of music. In appearance she was "a handsome, Spanish-looking woman with dark eyes and hair," a complete contrast to Richard Owen, senior, a typical "John Bull" in face and figure and with a bluff, burly, obstinate disposition. Owen himself was never tired of speaking of his mother's charm of manner and all that he owed to her early training and example. Of their six children, the eldest of the two boys—James Hawkins Owen—died at Deme-

\* "The Life of Richard Owen." By his grandson, the Rev. Richard Owen, M.A. Two volumes. John Murray, Albemarle Street.

rara of yellow fever in 1827. After some preparatory instruction from an old Quaker lady, Richard Owen at the age of six was sent to the Lancaster Grammar School. Nothing is to be seen of this school now, except perhaps the dated stone which used to be over the porchway. Whewell, the famous Master of Trinity, also received his education there, and another schoolfellow was Higgin, late Bishop of Derry. At that time Owen is said not to have exhibited any marked fondness for study. He would, his biographer says, speak feelingly of a day which recurred at regular intervals, known as "Black Monday," when the accumulated misdemeanours of the week were wont to be expiated. Rightly or wrongly, an increase in the pains and penalties was attributed by the scholars to Whewell, whose precocious relish for mathematics and study in general had considerably raised the standard of work, and Owen, though much his junior in age and standing, was loud in his taunting expressions of disgust. Whewell, in administering a reproof, excited the wrath of Richard's big brother James, and the result of his indignation may be gathered from a remark of Owen's mother, to the effect that she thought it most ungrateful of "that boy Whewell" to have "blackened her eldest son's eyes so shockingly." But the younger Owen and Whewell became the best of friends, and their friendly intercourse continued without a break until the latter's death in 1866. At the age of fourteen Owen had given no signs of a taste for the work to which his life was afterwards devoted. Heraldry appears to have been his earliest hobby. After leaving school he was apprenticed to Leonard Dickson, of Lancaster, surgeon and apothecary, on the death of whom he was "assigned, transferred, and turned over" to one Joseph Seed. A further transfer took place, when Mr. Seed accepted a post as surgeon in the Royal Navy, to Mr. James Stockdale Harrison in 1823. We gather how impressionable Owen's nature was on hearing that both his appetite and ardour for science were at the outset somewhat damped by the "natural awe which the human corpse inspired," even among the matter-of-fact surroundings of the dissecting room. At one time, after an unusually "uncanny" experience, he mentally vowed never again "to desecrate a Christian corpse and to quit a profession that could only be learnt by such practices."

In October, 1824, Owen matriculated at Edinburgh University. In the interval between that date and 1836 we find him M.R.C.S., in 1832 bringing out his memoir on the "Pearly Nautilus," professor on comparative anatomy at St. Bartholomew's, and F.R.S. in 1834, and married to Miss Caroline Cleft in the new St. Pancras Church, Euston Square, on July 20, 1835—his birthday. In 1837 Owen was elected to the professorship of anatomy and physiology in the College of Surgeons, vacated by the retirement of Sir Charles Bell. At about this time he began gradually to relinquish his medical practice in order to devote the whole of his time to scientific research. The Fullerman professorship of physiology at the Royal Institution he was obliged to forego, owing to a paramount engagement in relation to the catalogue of the Hunterian collection. In the same year, 1837, he was made a member of the Imperial Academy of Sciences at Moscow. In 1838 he visited Germany for the purpose of attending the meeting of German naturalists at Freiburg, and he relates in an amusing way how he and Mr. White Cooper obtained the use of the Prince Archbishop's carriage to enable them to take part in an excursion of the association by personal appeal to his Eminence.

"His Eminence was in bed, but the urgent Professor (Erchricht) was admitted, and set forth in glowing terms the merits of the two deserted scientists, the distant lands from which they had travelled, the estimation in which they were held by the 'association,' and especially the exemplary obedience to directions which had led to the disappointment caused by ruder—especially French—visitors. The Archbishop turned on his pillow, and, in choice ecclesiastical Latin, pronounced 'Then the last shall be first and the first

last,' and gave his orders to the attendant chaplain accordingly. The archiepiscopal coach being horsed and manned, the Professor rejoicingly returned with it to the Town Hall."

To enumerate in chronological order every step in this active and distinguished career would take too long. But, following him into his beautiful garden retreat at Sheen Lodge on April 13, 1865, we find him writing to his sister Maria: "We have now a lovely bed of Hyacinths out and the adjoining Tulip bed is beginning to show colour. The Horse Chestnut leaves are unfolding, but it is unseasonably dry. The orchard house shows a glorious blaze of blossom, with the bees busily humming and the warmth giving quite a mid-summer character to the interior. The wild Hyacinths, Arums, &c., I brought last year from Norfolk are all springing up or in flower. I think you will find the garden this year quite up to the mark."

In his declining years it was one of Owen's favourite amusements to observe the habits of the birds which frequented his garden, and the notes which he made upon his feathered visitors were, as he writes in his diary, "communicated to my friend Robinson's weekly paper—THE GARDEN—in successive numbers." The number of birds which the Professor noted in his garden at Sheen Lodge might well surprise even those who pride themselves on their observation of such things. "I have entered in my garden book," he writes, "the name of every kind of bird which I have noted there, distinguishing the permanent dwellers from the occasional residents, and the latter according to the periods of their temporary sojourn, whether to breed or to feed—in other words, the summer and winter visitors."

On January 5, 1884, Professor Owen was gazetted K.C.B. on his retirement from the British Museum, and on Mr. Gladstone's initiative his pension was supplemented by £100 annually. The death of his only son took place in 1886, and shortly followed that of his remaining sister. His closing years were passed at Sheen Lodge in the companionship of his eldest grandson until 1889, when his daughter-in-law and the rest of his children came also to reside there. His time was occupied chiefly with his correspondence and reading. He would, says his biographer, "read anything that came to hand, from the latest scientific work that was sent to him to the *Queen* newspaper, which journal was a source of unflinching amusement to him, owing to the numerous advertisements of hair dyes, washes for the complexion, and the 'anatomical impossibilities,' as he called the ladies of the fashion plates. . . . The love of his home and of his beautiful garden only grew stronger with his declining years. Every day he would go round his garden—no small distance—supported by his favourite curiously carved stick."

Early in the year 1889 Sir Richard Owen was seized with an attack of illness very like a paralytic stroke, from which he never entirely recovered. In his library, hung with medallions and miniatures of various men—Newton, Cuvier, John Hunter, William Cleft, Joseph Banks, and others—as well as oil paintings of John Hunter and Oliver Cromwell, he would sit for hours looking out wistfully at the park view, the little piece of water with the two old Oaks by its side, the wide expanse of green over the dark background of trees, his favourite companion a little black and white Persian cat.

"In the early morning of his last birthday (July 20, 1892) the tree which he admired more than any in the garden—the *Gleditschia*—fell down with a crash, leaving only part of the trunk and a few branches, although there was little or no wind at the time."

By a curious coincidence, says his biographer, on that day Sir Richard showed marked symptoms of failing strength. Shortly before his death he received a visit from the Prince of Wales, the Princess May, and the Duke of Teck, who stayed for some time and talked at his bedside. During the whole of his illness the Duke and Duchess of Teck and Princess May frequently came to Sheen

Lodge, and to stay and talk with him. On December 16 he ceased to recognise those that were standing around him and became very restless. A little before 3 o'clock on Sunday morning, December 18, 1892, he passed peacefully away.

The book is well printed and neatly bound, with portraits of Professor Owen at various stages of his life. It also contains a monograph by Professor Huxley on "Owen's Position in the History of Anatomical Science." The list of his honorary distinctions is long enough to fill nearly four pages of small type.

#### LIST OF TREES AND SHRUBS IN THE KEW ARBORETUM.\*

THIS, which deals with the Polypetalæ, is the first of a series of hand lists of the collections of living plants cultivated in the Royal Gardens which it is intended to issue from time to time. The importance and magnitude of the work may be judged by the fact of a rough census of the species and distinct varieties of plants cultivated at Kew, giving the total number as approximately 20,000, of which 3000 are hardy shrubs or trees. We are very glad to see a beginning of this list, for which we have only praise, but regret that the tree list was not published at the same time, as its being published in parts will necessitate several indices. As it is, it will perhaps be better to keep the present index in type and complete it, otherwise the book when complete will have several indices. It is an extremely useful and handy little book, and would have, perhaps, been better still if the size had been a little larger—more like the old Kew list of herbaceous plants, in fact. But we are very glad to get it in any shape, and we hope that the catalogue printing will continue until all the collections are embraced. It would, we think, be some improvement if the name of the genus were repeated in full on the top of each page in the case of large families.

#### A HANDBOOK TO THE PRIMATES.†

THESE volumes belong to the series known as "Allen's Naturalist's Library." Great interest attaches to the study of the monkey, whose habits, cries, and physical characteristics so closely resemble those of the human race, that sportsmen confess an unconquerable repugnance to taking his life, and even hardened naturalists speak with pain of the human-like distress which a wounded monkey exhibits. In these two moderate-sized volumes a great deal of information is imparted in clear and concise language regarding the habits, habitat, and physical characteristics of the monkey tribe, from the huge, ungainly gorilla to the graceful and soft-eyed lemur. The volumes, however, though clearly printed, are not well put together, and show a tendency to come to pieces with very slight handling. The coloured lithographic illustrations, too, seem to leave something to be desired, though this was probably unavoidable. It is, of course, well known to our readers that monkeys in gardens are not desirable visitors. In Northern and Central India, where the Hanuman monkey is held sacred and generally protected, it is no uncommon occurrence in the Northern and Central Provinces to see numbers of this species perched upon the roofs of houses. The damage they inflict on gardens and fields renders them a great nuisance. At Simla, the summer headquarters of the Indian Government in the Himalayas, a large troop of Macaques attached to the Hindu temple do considerable damage in the kitchen gardens of the mountain residences, so that the gardeners have to keep a sharp look out and fire upon them occasionally. Dr. Bowdler Sharpe, who was at Simla in 1885,

\* "Royal Gardens, Kew, Hand List of Trees and Shrubs Grown in the Arboretum." Part I.

† "A Handbook to the Primates." By Henry O. Forbes, LL.D., &c. Edited by Professor Bowdler Sharpe. Two vols. W. H. Allen and Co., Ltd., 13, Waterloo Place, S.W.

relates that the fakir who lived at the top of Jocko was much offended because one or two of his clients had been wounded in this manner. This man had tamed the monkeys to such an extent, that when he called them the trees instantly began to move in all directions with the approach of numbers of these animals hastening to him for the peas which he had in readiness for them. They clustered round him, and though they would not allow strangers to stroke them, they came within arm's length and picked up their food. One patriarch, who remained for some time after the tribe had disappeared into the trees, was called the "Subadar," and wore quite a venerable appearance. The picture will be familiar to many of our Anglo-Indian readers.

## FLOWER GARDEN.

### SNAPDRAGONS.

(ANTIRRHINUMS.)

Of the common Snapdragon, the garden varieties are now numerous, and often showy in effect, the best being the pure colours (*i.e.*, not striped). They fall into several "races," according to their height.

The race is divided into three sections based upon the length of the stems:—

1. Tall varieties.
2. Semi-dwarf varieties.
3. Dwarf varieties.

The large-flowered Snapdragon, even when wild, differs greatly, the result of situation, and when under cultivation through the efforts of gardeners to produce new varieties, so that it gives us from seed the greatest variety of form. These differences are, however, in the good kinds confined to the colour of the flowers and the tints of the foliage. Thus in a single mixed sowing, of the variegated Snapdragon it is often possible to find from twenty to twenty-five different forms as regards the flowers, although closely resembling each other in habit, height and foliage. So also with the semi-dwarf kinds. Still, amongst plants so dissimilar we shall find that certain colours and forms are reproduced from the seed with a certain degree of regularity. By saving the seed from such plants and re-sowing, we obtained a fair quantity true to their original form, and in the course of several years' sowings, by getting rid of all but the selected types, we obtained the first of our fixed varieties. A more difficult matter was to get rid of certain exceptional colours which sometimes showed themselves in mixed seedlings. The desire to obtain striking varieties is easy to understand; baskets of vari-coloured flowers, although pleasing when near, are when seen at a distance not so good in effect. On the other hand, by arranging the different varieties in groups of simple colours alternately we get striking effects and a certain fulness, it may be repose, but in any case effect is gained. In making our borders it was necessary to choose plants that were regular and of one colour, low-growing plants being preferred; and therefore we had recourse in the first place to the dwarf varieties.

Before giving a short description of the prettiest kinds let us say a word about the division of the Snapdragons into the three races according to height.

**THE TALL RACE.**—These plants attain a height of 1 ft. 8 in. to 2 feet (sometimes more) when closely planted, and in large beds in French gardens may be planted in groups of 6 feet or 8 feet, encircled sometimes by corresponding varieties among the dwarf kinds to a depth of a few feet. In smaller beds the plants may be isolated. The centre may be formed of

large baskets in places most exposed to the heat of the sun where few other plants could live. Sowings should also be made in order to obtain those superb branchlets which with their long spikes are so precious for the making of bouquets. Should the plants show too many flowerless branches, we have only to cut down the stems 4 inches from the soil, and six months afterwards they will produce fresh flowers.

**THE SEMI-DWARF RACE.**—These, which grow 1 ft. 4 in. to 1 ft. 8 in. high, may be used in the same way, and they lend themselves especially to the filling of baskets for which the habit of the large kind is too pronounced, and to the adornment of rockwork and of dry, arid walls. It is in this race that we find the greatest variety of colour. Though the flower-spike is not so long as in the preceding race, there is no decrease in the size of the flowers.

**DWARF, OR TOM THUMB RACE.**—In the old race of dwarf Snapdragon, or Tom Thumb, the plants for the most part had spikes of considerable length, and which were sometimes slender. Repeated selection from these has resulted in the production of plants of a peculiar habit and distinct race. The flower-bearing branches attain a height of 6 inches to 7½ inches, and a breadth of some 10 inches. They are composed of a great number of short, thick branches, the foliage being abundant and of a black-green colour. The flower-spikes are very thickly set, more especially in the case of the white-flowered and yellow-flowered varieties. Where many branches bloom at the same time the plant presents a mass of closely-set flowers, to which the foliage of the outer branches is as a frame. Other varieties are rather less dwarf, and their spikes have the form of enlarged cones, as with the feathery-flowered variety. The foliage of the race is throughout of a dark colour.

#### THE TALL VARIETIES.

**PURE WHITE.**—A superb plant, with pure white flowers, the bud a very pale greenish white, the swellings of the lower lip of a very clear yellow tint. The stems and foliage are of a handsome clear green.

**WHITE, WITH ROSEY STREAKS.**—Thin cherry-rose streaks or lines are traced upon the flower on a white-lilac-like ground. Both are very clear varieties, and, like the pure yellow described lower down, very precious for bouquets.

**BRILLIANT.**—A pretty purple and yellow flower.

**CRESCIA.**—A superb plant, flowers of a very decided red colour, but very striking. The tube of the corolla is reddish violet, also the underneath of the upper lip.

**DALIA.**—The tube and extremity of the lips of this are white.

**ELGANT.** This is of a beautiful decided red or carmine, a very brilliant colour coming between the clear and the pronounced tints.

**PURE YELLOW.**—Flower large and self, a very pure lemon tone.

**KERMESINA SPLENDENS.**—Flowers very large and spikes long, of a striking deep red colour, the lower lip still more so. The leaves are reddish violet in colour.

**NIGRICANS.**—The most pronounced colour of all, being a red-brown (almost black) and velvety.

**PANACHE.**—A mixture of colours, yellow or black ground and variegated, streaked or dotted with cherry-red or violet-red streaks or dots.

#### SEMI-DWARF VARIETIES.

**PURE WHITE.**—This is like the large-branching variety, but smaller.

**ROSY WHITE.**—A pretty, very pale, slightly lilac shade.

**CONSTANTIN TRITIAKOFF.**—Purple-red, lip yellow, tube white.

**FIREFLY.**—Handsome and large carmine flower with white tube, and on the swelling of the lower lip a yellow stain.

**NIGRICANS.**—Corresponds to the same variety among the large-branching kinds.

**VARIEGATED.**—Corresponds to the same variety among the large-branching kinds.

**PURPLE.**—The entire flower red, but the red on the tube duller.

#### DWARF VARIETIES.

**WHITE.**—The spike of this is very short and the blooms very large, whilst the swelling of the lower lip is slightly tinged with very pale lemon-yellow. The buds before opening are of a rosy yellow shade.

**YELLOW.**—Similar to the larger-growing form, the flowers of a very pure sulphur-yellow shade.

**COPPER COLOUR.**—Rather larger than the two preceding varieties. Flowers copper-red or mahogany on a yellow ground.

**VARIEGATED.**—A variety differing slightly from the race, the spikes being perceptibly longer. This should be 10 inches high or thereabouts and of equal width. The flowers are streaked and dotted on a yellow or white ground.

#### CULTIVATION.

Snapdragons are easy of cultivation, light sandy and cool soils suiting them perfectly. They are propagated from seed, which may be sown at different times of the year: (1) In August on the spot where they are to grow, or preferably in seed-beds, in which latter case plant close to a south wall, sheltering from continued frosts of 3° to 4° with dry leaves, straw, &c. Plant them out in the spring 16 inches to 24 inches apart. (2) In June or July in seed-beds in a well exposed position, planting out the seedlings in the spring. (3) In seed-beds (March to April) at the foot of a south wall. Transplant when the plants are sufficiently developed, and they may also be transplanted to seed-beds and planted out when the flowers commence to show themselves. By means of successive sowings it is possible to obtain an almost uninterrupted bloom from June until frost comes. Snapdragons are also propagated by cuttings made in the spring or summer, and even during the whole of flowering time. With Snapdragons, as with a great number of other plants, the colour of the stems and leaves of the young plants may to a certain point indicate to us what the colour of the flowers will be. Thus, kinds with green or light coloured stems and leaves will have in nearly all cases white, or mainly white flowers, or of which the colour is undecided; whilst of the plants which produce flowers of a decided colour, the stems and the leaves are of a pronounced green tint, more or less purple or ruddy also. In addition to the uses indicated above, these plants are specially adapted for ruins and rock gardens.—*Les Fleurs de Pleine Terre.*

**Red and white Daisies.**—For filling flower beds cheaply Daisies should not be lost sight of. If we start with a few dozen we can soon make them into thousands if required, and, unless through carelessness, we need never lose them. After they are lifted from the beds in May divide and plant out in nursery beds in a shady spot if possible and water for a time till established, and there will be plenty of stocky stuff to fill the beds in autumn. What soft lines of colour Daisies make if one really wishes for long, straight lines. I was kept waiting at a country station several hours last spring, and to while away the time I sauntered into the little village, and what a place for Daisies it was. Long lines of white and red Daisies led up to the cottage door in more than one garden, and very charming they looked. The red and white are most useful for filling beds or making edgings. The Hen and Chickens Daisy is less common and more expensive to purchase,

and the variegated leaved forms are more difficult to manage—at least I have found them so. A small bed filled with white Daisies and a broad band of red Daisies round will have a neat effect. They always look fresh, no matter what the weather may be, and if mild, flowers may be gathered more or less all winter. I could gather a bouquet of Daisies now if I wished, but I would rather see them growing.—E. H.

CAMPANULA RAINERI.

I HAVE no desire to prolong the discussion with Mr. H. S. Leonard on the subject of *Campanula Raineri*, as it appears to me to be both an unprofitable and an unseasonable one. Mr. Leonard tells us that his *employé* wrote to him, stating that this plant is very common in Italy; but, on the authority of botanical writers and from the information which I have received from two living botanists of Lombardy—the only ones who have taken up this question—I can assert that such is not the case. Further argument is, therefore, needless. I hardly think it worth while to defend myself against the malicious insinuation which Mr. Leonard makes against me personally when he speaks of my rooting up plants on the mountains, as the plant which gave rise to the discussion belongs to the class of "rare" plants which are the only kinds protected by our association, and also by the alpine clubs of several other countries, and I may just remind Mr. Leonard that this matter of rooting up rare plants originated with himself, and not with me. Four years ago Mr. Leonard accused our society of being the authors of the anti-*Phylloxera* laws, which do not permit plants to be sent by parcel post, unless officially certificated, to those parts of Europe in which the Vine is cultivated. At that time we had no trouble in proving to him that we had nothing to do with these laws, as our society was not founded until long after the promulgation of the said laws. It appears to me that Mr. Leonard is now eager to accuse us of other misdoings, but I shall not concern myself about the exoneration of our society. Mr. Leonard and I do not appear to have been created to understand each other. I shall, however, as strongly as possible dispute his claim to act rightly when, instead of supplying a plant which some customer may have ordered from him, he substitutes another plant which, in his opinion, is superior to that which his customer has ordered. He mentions, as an example, *Primula nivalis* (Hort.), which, in his opinion, is superior to *P. nivalis*, Pall. (the true species). I must here take exception to his views in this matter, as dealings of this kind are very detrimental to the good name and credit of horticulturists, and contribute to the introduction of the most lamentable confusion in the world of plants. For instance, in the case of the plant in question, I am not at all, and rightly so, of the same opinion as Mr. Leonard. In the modest Siberian plant I perceive a grace, an elegance, a purity of form, in fine, a poetry of expression which is not to be found in the *P. nivalis* of the gardens, and I can well understand how an amateur who is alive to this poetic expression and delicate language of the flowers of the snowy regions would be anxious to obtain the aristocratic *P. nivalis* (Pall.), more especially if he had already on his rockwork the rich *parvum* which bears the same name. Under any circumstances I deny that the vendor of any kind of wares has the right to prescribe to me in matters of taste. I may admire a certain plant and prefer it to some other plant which my neighbour values more highly. Individual tastes and ideas of colour are no subjects for argument.

In conclusion, permit me to repeat my former advice to Mr. Leonard, viz., raise your plants from seed, and you will have them hardier and more healthy than plants from the mountains. I have never succeeded with any of the plants which Mr. Leonard has sent me from his nursery, except a solitary *Crocus* bulb. But I do not find fault with the condition of these plants. On the contrary, I know by experience that plants with

thick, heavy, tumid tissues never succeed in a dry climate like ours, while, on the other hand, it is equally true that plants raised in our dry, warm climate, where they cannot grow as they would in England, succeed ever so much better when transferred to a suitable climate in which they can find themselves as much at home as they appear to do in England.—H. CORREYON.

— May I send just a line on M. Correyon's behalf? It so happens that I am well acquainted with his usual practice. About five or six years ago I accompanied him on one of his botanical expeditions among the mountains to the south of Martigny. His headquarters were at Mauvoisin, and from thence he proceeded to his work. On one occasion he set his heart on the ascent of Mont Avril, and I went with him to the end of my tether, when he and the guide left me, and I had to solace myself for seven or eight hours as best I could on a plateau not very far from the huge glacier D'Otemma, amidst a profusion of *Anemone vernalis*, *Azalea procumbens*, *Soldanella*, *Gentians*, &c. In the evening M. Correyon returned with his hands and his case full of the blossoms of *Eritrichium nanum*, *Androsace obtusifolia* (I think), *Gentians*, &c., but he had not a single rooted plant with him, nor did he display one at the little inn at Mauvoisin in the evening—nor did he take one back with him to Geneva—of any sort, to the best of my belief, as the result of his journey. On the contrary, the burden of his song invariably was that alpine plants should be grown from seed, and I have seen him over and over again bounce down avariciously upon the seed-vessel of some scarce plant which he desired and carry it off with him. Besides, it is not to be supposed that well-known savants, bankers, &c., of Switzerland and other countries would allow themselves to be stultified by the action of one in whom they put (to my knowledge) the greatest possible trust. I have read Miss Willmott's note in your impression of December 15, and I quite agree with what she has said. H. EWBANK, *Ryde, Isle of Wight.*

DECEMBER IN SOUTH DEVON.

THE past December has been a comparatively warm and sunny month, the mean temperature being 45.5°, or 3.9° above the average, while the sunshine recorded (73 hours 10 minutes) is 15 hours 45 minutes over the usual allowance for December. On twenty-one days has the sun shone, and on only six days, or rather nights, has the thermometer on the Grass fallen to freezing point, the lowest reading being 24.8° on the 31st. Rain fell on twenty days to the amount of 2.21 inches, or 2.77 inches below the rainfall of December, 1893, and 1.01 inch below the average, which is 3.22 inches. The total rainfall for the twelve months amounted to 43.23 inches, an excess of 7.74 inches over the average of 35.49 inches. The year's sunshine, on the other hand, has been decidedly meagre, being no less than 432 hours 35 minutes below the sunshine of 1893. For twenty-seven days out of the thirty-one the wind has been in the south or west, and throughout the month has been boisterous, the total horizontal movement having been 9292 miles. The greatest velocity was reached on the 22nd, when 734 miles were recorded, a rate of 44 miles per hour being registered between 4 and 5 a.m., some of the gusts travelling at the rate of 100 miles an hour. On the 2nd I picked a large bud of *Magnolia grandiflora*, which opened well indoors, and until the frosts of the last two days of the month unseasonable blooms of many species of flowers were noticeable, among them being *Doronicum Harpur Crewe*, *St. John's Wort*, scarlet *Genm*, and *Myosotis*. *Primroses* have commenced to bloom in the sheltered nooks of the lanes, and a few *Tea Roses* might have been picked from the south walls on most days of the month. On

a warm terrace, trained up the sheltering rocks, *Physianthus albens*, a little-known climber, was flowering in the open during the second week of the month, and *Solanum jasminoides* is still producing its graceful sprays of white blossoms. The giant *Christmas Rose* (*H. maximus* or *altifolius*) has been in bloom now for nearly three months, and seems likely to continue for another three weeks. As a rule it is over before *Christmas* and does not commence so early as *October*, which this year it did, the first flower being picked on *October 18*.

Many plants will suffer severely from the damp and open autumn and winter. *Tree Paeonies* had pushed out young growths fully 6 inches long. These have been killed by the frost of the 31st. Plants of *Agapanthus umbellatus*, which had been covered up with matting and had passed through much harder frosts unhurt during last winter, have also been damaged owing to the sappy condition of the leaves, but the crowns being well matted with a thick layer of leaf-mould will probably escape injury. Bulbs generally do not appear so unusually forward as they seem to be in some localities. Let us hope that what we lose in earliness we may gain in prolonged and bounteous supply. S. W. F.

FLOWER GARDEN NOTES.

HERBACEOUS PLANTS FROM SEED.—Although in the majority of places little attention is given to raising a stock of herbaceous plants in any variety from seed, it is a question if it is not a branch of flower gardening that does not deserve more attention. One is sometimes met with the argument that we have plenty of bedding plants for the formal garden, and many herbaceous plants are short-lived so far as their flowering season is concerned, and are, therefore, hardly admissible in prominent places where a good and constant supply of bloom is required for a given time. This may be partly true, but in the case, for instance, of *Antirrhinums*, *Pentstemons*, *Carnations*, *Violas*, &c., we have even a longer flowering season than is obtained from the majority of tender plants; whilst others that are more quickly out of flower, as *Pyrethrums* and *Columbines*, are beautiful in their foliage, and may at any rate be planted sparingly in clumps with other things. Take also the case of herbaceous borders. Are they full of good things, or is there a mixture of weedy rubbish and a lot of shrubs and small conifers that are quite out of character on such? If so, by all means (as excellent strains are now obtainable from all the best firms) secure packets of seed of such things as *Poppies*, *Pyrethrums*, *Carnations*, *Polyanthuses*, *Aquilegias*, *Antirrhinums*, *Pentstemons*, *Campanulas*, *Foxgloves*, *Verbasiums*, and *Delphiniums* that will in their respective heights furnish a grand display. Even if not wanted for flower garden planting they are sure to be useful, and in all cases where there is a great demand for cut flowers I would say never be without your nursery beds of perennials. A small stock in variety once obtained, the best seedlings can be selected for future seed saving and sowing. Fortunately, too, in the case of the majority of hardy flowers one is, with careful selection, fairly certain of a good plant, good average flowers, both individually and in the spike or truss, and occasionally some interesting new departures. All species that will flower the same season if require I should be sown early, say about the end of February, either in a pit or preferably in boxes, placing the same in a vinery that is at work not too far from the glass. Let me, however, strongly advise all who are contemplating raising a stock of such plants not to attempt more in the spring than they can manage well. If there is a possibility of other work pressing rather hard at this season, it is best to defer the sowing until the end of the summer; transplant and plant out in spring. Naturally, nearly all the family being hardy can be sown in the open, and where this is

done it is advisable to use a rough frame or pit so as to have the scollings close under the eye, and be able to guard against enemies in the way of slugs, maggots, or birds.

**ANNUALS.**—The selection of the commoner annuals for flower garden work depends greatly, I may say entirely, on the requirements of different places. They are not as a rule very largely used in old established gardens, the beds or outlying borders in which they lived out their brief existence being gradually filled up with perennials. I only grow a few now, and these are either for special places or for a special purpose. For the former trailing *Tropaeolums* and *Convolvulus minor* in variety may be cited as examples of plants suitable for covering quickly bits of rough ground; whilst for rather poor borders on a large or small scale, the three varieties of Malope, crimson, rose and white, and the new Toadflax (*Linaria aurea reticulata*) would be found suitable. The enduring properties of the Malope in a cut state are not, I think, generally known, and are somewhat remarkable considering the rather flimsy appearance of the petals. I was led to note this by seeing some shoots that had been picked from the plants and left on the bench in a shed, dry and hard in the stem, but showing the flowers at the end of four days apparently as fresh as when the shoots were severed from the plant. There are some of the annuals that are very useful, almost indispensable, indeed, for summer cutting, and I always find room for a good batch of these even if they have to monopolise some portion of the kitchen garden borders. *Gaillardias* and *Godetias* are in a cut state among the most enduring annuals, and, it may be added, will flower all the longer if the ground in which they are sown has been well manured and deeply dug. There is no better white-flowering annual than Princess Alice Stock, its branching habit, which enables one to take off individual blooms with quite a nice piece of stem, being a special point in its favour. A good white Aster is Comet, the habit of the flower rendering it more valuable for cutting than the very formal types. In yellow shades the two best annuals are possibly the yellow form of Iceland Poppy and the miniature Sunflower; the latter may be sown early in a little warmth to get it quickly into flower; it will pay for a bit of good ground, and if the flowers are cut fairly hard it will continue to bloom until late in the autumn. If it is proposed to sow Sweet Peas in pots, they should go in towards the end of the month, but I do not think there is much gained by the practice, especially if a spell of cold sets in just as the young plants are turned out in the open. One gets equally good results by sowing outside in February, always provided a piece of ground that has been well manured and trenched is chosen. Varieties of really good Sweet Peas are now so numerous that it is rather difficult to make a selection. For growing in quantity, Mrs. Sankey, Princess Beatrice, Captain of the Blues, and a thoroughly good strain of Invincible Scarlet may be recommended. Of a few newer and more expensive varieties tried last year, I was very pleased with Stanley, Countess of Radnor, Venus, and Mrs. Eckford. Provision must always be made for a good breadth of that indispensable annual Mignonette; it is always thoroughly at home in the decomposed mulch and rather stiff soil to be found in the beds of dwarf Roses, and a sowing may be made here and another on a portion of a north border. This is a chance crop, not of much use, perhaps, in a season like that of 1894, but coming in very useful, given a long spell of hot, dry weather in August and September.

Claremont.

D. BERRILL.

**Iris Kœmpferi.**—I must thank "E. J." and Mr. T. Smith (p. 521) for their notes on the above. I think that in all probability my failure must be attributed to heavy soil. Nursery catalogues are eloquent regarding the copious supply of water necessary, but silent as to soil. Evidently with heavy soil too much water is harmful, and it is better to err in the other direction, viz., that of

dryness. There is no lime in the soil, so that this possible cause is disposed of. I shall substitute leaf-mould, mushroom-bed manure and sand for the present soil and hope for better results.—S. W. F.

### THE GLADWIN.

(*IRIS FETIDISSIMA*.)

**IRISES**, with few exceptions, are mostly grown for the beauty of their flowers. Our common yellow Water Flag, which with the Gladwin re-

got from the flower garden in summer is obtained with the finer dried Grasses, "Everlastings," and the Gladwin. We saw lately a vase filled with Grasses, Gladwin, and the orange-red calyces of the Winter Cherry, more appropriate to the season than forced things from the stove. It is delightful when wandering in a wood to come across a colony of this flower, the plant itself spreading out into a dense tuft, the leaves long, dark green, changing as winter hastens away to a lighter "drier" tone. It may be

*The Gladwin (Iris fetidissima). From a water-colour drawing by Agnes Cook.*

presents the family in Britain, is not the least charming in a lovely race, but the Gladwin represented in the accompanying sketch has no flower beauty. Its value is in its brilliance in the winter months, with the delicate brown capsules burst open to display the rows of orange-red berries enclosed within. One can get a winter picture with a group of the Gladwin, the leafage remaining with the stems and displaying glaucous shades, passing to a light brown at the tips. In the early winter months bunches of its berry-bearing stems are sold in the shops, and as pretty a bouquet as may be

naturalised in open places and should be in the garden proper, one use for it being to clothe a dry bank, whilst even under the shade of trees it is happy. A group of it is worth planting if only for cutting for the winter. We may mention the variegated variety as worth consideration. Variegated plants as a rule are things to avoid, but this is pretty and useful.

**Alstroemerias.**—I observe that my note on the above created a smile, but whether "North Cheshire" was amused at my inability to grow *Alstroemerias* when treated as ordinary border

plants or because they are so rarely seen in gardens, "at least in this county," or because he is so very successful with them, he does not state. "North Cheshire" has the soil for *Alstromerias* which at once accounts for his success. I have just the contrary, as, in fact, most of the gardeners have in this county. I did not say that it was owing to their tenderness that these plants failed to grow in the open border. Neither could I think this to be the case, at least with *aurantiaca*, knowing the depth to which the tubers descend. "North Cheshire" must remember that all the species are not hardy. For instance, *A. chilensis* is of doubtful hardiness; so is *pelegrina*, also *p. alba*; *pulchra* is safer when protected a little. I am able to grow the more tender varieties under the conditions I mentioned in my note of December 15. Even *aurantiaca* does not flourish on these hills under ordinary border treatment. The subsoil is altogether unsuitable for it, being too cold. Of course there are exceptions I have no doubt. Cancn Ellacombe, of Bitton, can grow it in almost any spot in his garden. If "North Cheshire" does not possess or know *pelegrina*, I can strongly recommend it.—THOS. ARNOLD, *The Gardens, Cirencester House.*

**Puschkinia scilloides.**—This lovely Squill-like spring-flowering plant has not taken that place in our spring gardens its merits deserve. Probably the price at which it is sold is to some extent a prohibitive one, as this militates against its being employed in masses, when it can be seen to great advantage. It is so employed at Belvoir in the adornment of the spring garden. At Belvoir, in common with *Chionodoxa* and some others of a like character, the plants seed freely. In the large trial garden the late Mr. Ingram used to grow large patches as a reserve.—R. D.

**Primrose culture.**—When at Belvoir Castle in the spring of 1893 I was much interested in the method adopted by the late Mr. W. Ingram in preparing his plants of coloured Primroses for planting out in the beds in his spring garden. He always had a succession of strong seedlings coming on, and they were planted out on a bed made up of manure and leaves 2½ feet deep, and then covered with rich soil, in which the seedlings were planted. Here they made a vigorous growth, and the advantage was seen in the wealth of bloom given when the plants were transferred to the spring beds. In the case of beds of Primroses and also plantations of *Polyanthuses* this condition of things is well worthy of being imitated. The roots enjoy a bed of manure below; coolness, moisture and food are thus furnished, and reproduced in superb heads of bloom. Some of the choicer varieties of double Primroses could be better grown and kept through the summer if treated in this way.—R. D.

**Verbascum phœniceum.**—You may not think the correction of sufficient importance to allow it a space in your paper, but there can, I think, be no doubt that the description of the plant (engraved on page 519 in your issue, December 22) does not apply to *Verbascum phœniceum*, but to *Verbascum nigrum-album*. The latter is a native of England, and is well described by your correspondent "J. E. N.," and it reproduces itself in endless quantity by seed. *V. phœniceum* comes from Southern Europe and is a hardy perennial. I have long grown both kinds, but during a period of more than fifty years the latter has never ripened seed in my garden, though I am aware it has occasionally, but rarely, done so elsewhere. Neither did I ever meet with a white variety.—J. H. ARCHER-HIND, *South Devon.*

**The weather in West Herts.**—All the last ten days have been unseasonably cold, and on each night the exposed thermometer has shown more or less frost. The coldest day, however, of the present winter was the 7th, when the temperature in the shade at no time exceeded 39°. The coldest night also occurred during the past week, being that preceding the 6th, the exposed thermometer then indicating 15° of frost. At 2 feet

deep the temperature of the ground is now only 5°, and at 1 foot deep only 3° above freezing. These are low readings even for midwinter, but, nevertheless, not as low as those recorded at the same period last year, when the ground at both depths was about 1° colder. Snow has already fallen on six days this month, but on only two of these was the ground completely covered, and then to the average depth of less than 1 inch. The last few Rose blooms of the past season were destroyed by frost during the night preceding the 31st of December, which is fully a month later than the average date for the last Rose in the previous nine years, and later than in any year since 1886, when there was still a bloom to be had on January 6.—E. M., *Berkhamsted.*

ABSURD GARDENING IN CHICAGO.

WE see in Mr. Falconer's very pretty little paper *Gardening*, published in Chicago, a horrible example of carpet gardening, in which large vases, bandaged over with black and white lines, are made to spring up from the ground, and in the middle of all a fearful representation of the globe, belted round with dark lines. This remarkable object—"the crowning feature of the design," as it is styled in the accompanying letterpress—is thus described:—

The globe is 12 feet in diameter and rests on a circular pedestal 12 feet across, that slopes from 2 feet in height at the sides to 3½ feet in the middle. It is planted on the sides with the purple-leaved *Oxalis* and on the top with *Othonna crassifolia*. On the globe the water is represented by *Echeveria secunda glauca*, the continents and islands by the purple *Oxalis*, the equator by yellow, and the meridians by red *Alternanthera*. The globe has been used several years, and sometimes the equator and meridians are made with *Sempervivum tectorum*. The globe, being so large, is made secure in its place by a strong timber running down through the south pole and passing on through the pedestal into the firm earth beneath, like a long, well-set fence post. The pedestal is made in much the same way, except that the upright posts of the frame are set in the ground, and common lath (instead of wire) are nailed on, leaving spaces 1 inch in width. A sufficient space at the top of the globe is left unwired until the soil is packed in up to that point, after that wiring and filling go on little by little until the globe is a solid ball of earth. The soil used is heavy clay loam with a little sand, and it is made very wet and then tamped into position. The vases and all the pedestals are filled in the same way. The equator and meridians are planted, and after being outlined with pegs and string, the continents and oceans are also planted. The planting is done by the aid of a small pointed stick with which holes of a suitable size for the various plants are made in the spaces between the wires, and into each hole, as made, the roots of a plant are dextrously twisted, the soil pressed closely about them, and so on, until "the mighty ocean and the pleasant land" are all simulated in growing things. The plants are set so rarely touch each other, which allows some room for growth, but sometimes they pile themselves up in odd groups that give a somewhat stormy appearance to the ocean, and cruminate the vases in a rather decorative fashion.

The "world" is watered as any carpet plant would be, possibly requiring a little more than the average amount of moisture to make up for the rapid evaporation due to the exposed position. The vases are treated likewise, the water being usually applied, in their case, by means of a garden syringe that is used daily. Watering with a fine rose nozzle on an ordinary hose is, however, not at all injurious to plants in such positions. The blossoms of *Echeverias* are generally kept cut from the plants, although in some cases they are left and prove quite ornamental. After frost ends the out-of-doors flower season the plants are all removed from the globe, vases, pedestals and beds of this design, the soil is worked out of the vases, and they are stored indoors until spring, when they are repaired, refilled and used again wherever needed. The globe, however, is usually left in position, and in spring it also is repaired and refilled.

This is the sort of thing that makes flower gardening ridiculous in the eyes of all educated and artistic people. No human being could find so ugly a thing to draw among natural and artistic things, and the utmost that can be said for such rubbish is, that it may go along with the

minor work of the so-called decorative artist, wall-papern, pastry-cooks, and other folk who call themselves artists while doing mostly ugly things. We regret to see public gardening in America, where there have been such good gardens and parks made by Mr. Olmsted, degraded by a wholly needless and inartistic mode of setting out plants, unnatural and contemptible in every way.

NOTES OF THE WEEK.

**Catalpas and Tulip trees in Yorkshire.**—Can any reader tell me if *Catalpas* and *Tulip trees* would succeed and flower in sheltered positions as far north as the West Riding? I have seen none in this district. Persons whom I have asked about them cannot give me any information.—J. EASTER, *Nostell Priory Gardens.*

**Meconopsis Wallichii.**—I see Mr. Wood says *Meconopsis Wallichii* likes as much sun as it can get. My experience is quite the opposite. It does perfectly here now in total shade; whereas it used to flag in a wet, shady place and lose colour. The only protection wanted is from strong winds, which destroy the foliage.—F. PAGE-ROBERTS, *Scots Rectory.*

**Coreopsis grandiflora.**—Your picture of this is so well done, that no one looking at it would mistake it for *Coreopsis lanceolata*, as many do when seeing it in a cut state. The difference is not in its greater size of bloom, for a well-grown *C. lanceolata* is quite as large, but in its shape and colour, and yet many who know have a difficulty in dividing the two when mixed in a bunch. The foliage of seedlings is very distinct. I find it quite hardy and perennial, but it is better treated as an annual; the flowers are much finer. Seedlings self-sown spring up and grow well in my garden.—F. PAGE-ROBERTS, *Scots Rectory.*

**Almonds fruiting in Ireland.**—Under the above heading a note appeared in a recent number of THE GARDEN. Surely this cannot be of such rare occurrence in a country where flowering and ornamental trees and shrubs, as a rule, do so remarkably well. But is it not more unusual for the Almond to perfect its fruit in this part of Yorkshire? Some fruit I enclose you will see appears to be perfectly ripe and of fair size. The tree on which the fruits were grown was covered with its handsome bloom in early spring, and was a conspicuous object at a considerable distance.—J. EASTER, *Nostell Priory Gardens.*

**What's in a name.**—I am relieved by knowing, on good authority, that the name *Imro-glossa albescens* does not exist in botany. It certainly does not exist in any respectable spoken or written language, for one thing at least which there ought to be in this name is the letter H. The Greek for "a longing desire" is not "imeros," but "himeros." So, too, the Greek compound adjective meaning "strap-leaved" is not "imantophyllum," but "himantophyllum," and it is just as barbarous and execrating to drop the H in this word as it would be to call a Sunflower an *Elianthus*. If it is necessary to coin these terrible yard-long words, let them be coined by scholars, at all events.—G. H. ENGLEHEART.

**Gomphia decora.**—The genus *Gomphia*, although calculated by botanists to contain about four-score species, natives for the most part of South America, is only represented by one species in English stoves that can be described as at all well known. This species is *G. decora*, also known as *G. oliva-formis*. Flowering, as it does, more than once during the year, but rarely missing the two darkest months of winter—November and December—its value is greater than that of many plants which are more grown. It has large, shining, deep green leaves not unlike those of the Cherry Laurel. The flowers are produced in erect racemes measuring 4 inches or more high, and about half as much through. On these racemes the blossoms are closely packed, each one being

about 1 inch across, the five spatulate petals being of a rich bright yellow. The plant is not a fast grower, and does not need the pruning that so many other stove plants do to keep them in proper bounds. It was introduced from Brazil in 1868.—B.

**Chrysanthemum King of Plumea.**—I send you a spray of bloom of *Chrysanthemum King of Plumes*. The plant was in bloom on the 10th of December. The sprays exhibited on the 11th at the Drill Hall were cut from the same plant as those sent. I left one spray to see how long it would remain fresh on the plant, and I leave you to judge as to the value of the flowers for keeping. Cut blooms as a rule keep longer when cut and placed in a sitting-room than on the plants.—ROBT. OWEN, *Maidenhead*.

\* \* A delightfully interesting kind, finely cut and varied in the shape of its petals, evidently very late, and as a decorative plant (as the phrase is now-a-days) would be charming.—ED.

**Rose Mrs. Grant.**—We have sent you a few specimen blooms of our new Rose the Belle Siebrecht (H.T.), which was at first named Mrs. Grant, and exhibited under that name by the raisers, Messrs. Alexander Dickson and Sons, Newtownards, Ireland, from whom we bought the entire stock some two and a half years ago. We have grown this Rose under glass in this country, and find it not only one of the best for forcing, but it also does splendidly out-of-doors here, and has proved perfectly hardy. Dean Hole pronounces the colour a true pink, without any combination colours. It is a free bloomer and a strong grower, not subject to mildew. It promises to be one of the finest Roses for cutting ever offered.—SIEBRECHT AND WADLEY, *New York*.

\* \* Large and handsome buds, but not in sufficiently good condition to enable us to see the true colour. If this Rose was first named Mrs. Grant, and won prizes under that name in England, it is perhaps a pity to change it.—ED.

**Bambusa mitis.**—It may interest the readers of THE GARDEN to see a copy of a record which I made of the growth of a young shoot of *Bambusa mitis*. On Sunday, June 25, 1893, at 7 p.m. the shoot was 3 feet 6 inches out of the ground: on June 26, 10.30 a.m., it had grown 3.2 inches, and at 7 p.m., June 26, 2 inches more. Total for the 24 hours, 5.2 inches. Growth to June 27, 10.30 a.m., 4.2 inches, and June 27, 7 p.m., 2.6 inches. Total for 24 hours, 6.8 inches. Growth to June 28, 10.30 a.m., 3.3 inches, and to June 28, 7 p.m., 1.6 inches. Total for the 24 hours, 4.9 inches. Growth to June 29, 10.30 a.m., 3.3 inches, and to June 29, 7 p.m., 1.75 inches. Total for the 24 hours, 5.05 inches. Growth to June 30, 10.30 a.m., 2.25 inches, and to June 30, 7 p.m., 2.5 inches. Total for the 24 hours, 4.75 inches. Growth to July 1, 10.30 a.m., 3.25 inches, and to July 1, 7 p.m., 2.5 inches. Total for the 24 hours, 5.75 inches. Growth to July 2, 10.30 a.m., 5.2 inches, and to July 2, 7 p.m., 5.85 inches. Total for the 24 hours, 11.05 inches. Total for the 7 days, 43.1 inches. Unfortunately, I was obliged to leave home on July 3, and further measurements were not taken. The circumference of the cane is 4 inches.—E. G. LODER, *Leonardslee, Horsham*.

**The Williams Memorial Fund.**—At a recent meeting of the Williams Memorial trustees it was decided to offer large silver medals at the following shows, to be held during 1895: Newcastle-on-Tyne, for the most meritorious specimen flowering plant; Richmond, for the best collection of vegetables; Crystal Palace autumn fruit show, for the most meritorious collection of fruit; Trentham, for the most meritorious collection of fruit. A sum of two guineas was also voted to the fund being raised for the benefit of the Lindley Library.

**Royal Horticultural Society.**—The next meeting of the R.H.S. will be held in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, January 15. The new committees will assemble at 12 o'clock noon precisely.

## PUBLIC GARDENS.

**Bournemouth pleasure grounds.**—At a recent meeting of the Bournemouth Town Council the Mayor read a letter from Sir George Meyrick's solicitors, in which it was stated that Sir George would be willing to hand over the cliffs to the borough as pleasure grounds provided the question of an undercliff drive was finally settled, including the approval of plans and estimates showing the scheme to be feasible, and further, that he was prepared to contribute to the cost, but to what extent would depend very much upon what the cost of the scheme would be. The cost has been estimated at from £60,000 to £100,000.

**Metropolitan Public Gardens Association.**—At the monthly meeting of the Metropolitan Public Gardens Association, held at 83, Lancaster Gate, Lord Dorchester, vice-chairman, presiding, the Bishop of Southwark was elected a vice-chairman. A draft of the twelfth annual report was laid on the table and adopted, together with the audited statement of accounts for the year 1894, showing an income of £4300, against £6600 in 1893, and an expenditure reaching £5400, necessitating a considerable call upon the reserve fund to make good the deficit. It was announced that grants of £20 and £10 10s. had been received from the Grocers and Salters' Companies, and that a lady had sent £25 for a drinking fountain; that trees had been planted at the suggestion of the Association in Exhibition Road, and that the Association was in negotiation for the purchase of a site for a playground in Deptford. It was agreed to give £160 and seats towards the laying out of Bartholomew Square, to make inquiries about a site in Hornsey Road offered to the Association, to communicate with the Commons Preservation Society respecting the alleged threatened enclosure of Ham Common, and to lay out the eastern end of the churchyard of All Hallows, London Wall, if the rector would maintain it as a public garden. Letters were read respecting many schemes on hand, and it was announced that the New River Company declined to allow their ground in Canonbury to be thrown open, that the London County Council was no longer prepared to purchase a site in Flower and Dean Street, a small portion of which had been built on, and that the residents in Munster Square and Clarence Gardens and the promoters of the Gliddon Recreation Ground declined to entertain the proposals of the Association for the opening of these enclosures.

**The Yorkshire Gala.**—The thirty-seventh annual meeting of the guarantors and life members of the Grand Yorkshire Gala was lately held at Harker's York Hotel. The chairman, Alderman Sir Joseph Terry, J.P., presided, and there was a large attendance of members. The chairman congratulated those present on having again met under encouraging auspices, and proposed the election of the Mayor (Mr. Alderman W. McKay) as president for the present year. Mr. Councillor Border seconded, and the proposition was unanimously carried. Mr. Alderman Milward then proposed the re-election of Sir Joseph Terry as chairman. Mr. M. Cooper seconded the proposition, which was unanimously carried. Mr. Joseph Wilkinson was re-elected treasurer and Mr. Chas. W. Simmons was unanimously re-elected secretary. The floral, financial and entertainment committees were elected, and the following grants were made: For prizes to the floral exhibition, £600; for music, £120; for fireworks, £100; for balloon, £60; and for amusements, £175. The amounts are similar to those of last year, with the exception of the last, which is increased.

**Sciadopitys verticillata** (the Umbrella Pine of Japan).—I have often wondered why this distinct and handsome conifer has not been planted more extensively, considering that it has now been introduced close on thirty years. Possibly it has been planted in too dry positions; if so, this one fact alone would be sufficient to account for

failure. Like many other of the Coniferae, it delights in moisture at the roots. I well remember a fine plant several years ago in a well-known Surrey garden. This was planted on rather elevated, but moist, swampy ground where *Rhododendrons* grew most luxuriantly. Here the Umbrella Pine was quite at home. The position, it should be stated, faced east, thus of its hardness there could be little doubt. In the Lake districts and in North Wales also it should find a congenial home, note having been taken of how surprisingly well most of the choicest of the Coniferae thrive in these localities. Its close bushy growth and pyramidal outline are decidedly distinct.—G.

**"The English Flower Garden"** (A. T.).—This is being revised and reprinted, and will be issued in the spring. There are some advantages in delay, inasmuch as the book, not being stereotyped, admits of revision. The new edition will contain an account of the Bamboos, by Mr. A. B. Freeman-Mitford, and a revision of the hardy Water Lilies by Mons. Latour-Marliac, the Narcissi by Mr. Burbidge, the Lilies by Dr. Wallace, out-door Chrysanthemums by Mr. Molyneux, Tea Roses by Mr. Herrington, and many other additions. The first part, *i.e.*, that devoted to design, will have important additions and plans of showing planting of flowers as well as plan to scale.

**"The Garden" Index to the second 20 vols.**—Several friends having expressed a wish that an index of the second twenty volumes of THE GARDEN should be compiled and printed as a separate volume, we shall be happy to undertake its preparation if one hundred subscribers will put down their names for it. Without this we could not undertake it, as the labour of preparing and printing would be so heavy. The name of each subscriber would be printed in the volume. The price to subscribers will be one guinea, which will be increased on the day of publication. The following names have come to hand:—

*Mrs. Robb, 42, Rutland Gate, S.W.*  
*Mr. A. B. Freeman-Mitford, Batsford Park, Gloucester.*  
*Mr. W. E. Gumbleton, Belyroce, Queenstown, Co. Cork.*  
*Mr. E. H. Woodall, St. Nicholas House, Scarborough.*  
*Mr. Granville Ryder, 60, Ennismore Gardens, S.W.*  
*Mr. J. F. Bennet-Poë, 29, Ashley Place, S.W.*  
*Mr. Greenwood Pim, Dublin.*  
*Baron Von St. Paul, Silesia.*  
*Miss Hals, Shipley House, Carshalton.*  
*Mr. D. T. Fish, Bury St. Edmunds.*  
*Mr. W. Brockbank, Manchester.*  
*Mr. T. H. Archer-Hind, Norton Abbot.*  
*Mr. G. Muirhead, Hadido House, Aberdeen.*  
*Mr. F. W. Moore, Royal Botanic Gardens, Glasnevin (2 copies).*

## TRADE NOTES.

**Forestry honours.**—The "honours diploma" for the science and practice of forestry has been granted to Mr. James William Watt, eldest son of Mr. James Watt, by the Grand Ducal Forestry College at Eisenach, in the duchy of Saxe-Weimar, in which Government Academy of Forestry he has been studying. He will henceforth be associated with his father, the head of the seed and nursery firm of Messrs. Little and Ballantyne, Carlisle.

## BOOKS RECEIVED.

"The Rosarian's Year-book for 1895." By the Rev. H. H. D'Ombraim. Bearose and Sons, Old Bailey, E.C.

"Guide Élémentaire de Multiplication des Végétaux." With 85 illustrations. S. Mottet. Octave Doin, Paris.

**Names of plants.**—Edward Ingram.—*Cypripedium Dautliieri*.

**Names of fruit.**—Dunham Massey.—Pears: 1, *Bearré d'Arenberg*; 2, not recognised; Apple, specimen too poor.

No. 1209. SATURDAY, January 19, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHARD AND FRUIT GARDEN.

### GRAPES WITH ORNAMENTAL FOLIAGE.

THERE appears to be an increased demand for Vine leaves with beautiful tints during the early winter months, not only for dishing up dessert, but also for table decoration, and for dishing white Grapes or any other fruit that is pale in colour nothing sets it off to such advantage as finely marked Vine leaves, the red in them showing up the fruit beautifully and far better than is possible with green foliage by lamp-light. My ideas may perhaps be considered not up to date in preferring green leaves for dishing up black Grapes or any other fruit that is dark or red in colour, but my contention is that the green leaves form a better contrast than those that are strongly marked with red, which is too closely allied to the black or red in the fruit to show up in the best form. Again, unless the table is very large, I think Vine leaves, although splendidly coloured, have a somewhat heavy effect, and are neither so pretty nor effective as something smaller and lighter. However, in many gardens it does not signify much what the gardener may consider pretty or otherwise; he must do his best to try and meet the wishes of his employers, and whatever they require done, strive to do it well and thus give satisfaction. Some ladies and gentlemen have been so delighted with the use of coloured Vine leaves for the purposes named, that a good price has been paid for such foliage, and in one instance a gardener had trouble because he could not produce the same. Fortunately, evidence was brought forward to prove that soil and its constituents exercise an influence on the colouring, and also that certain varieties will produce lovely leaves in the autumn, while others fail to do so in spite of all efforts. Out of many varieties of Grapes grown in various parts and on different soils, I never found any sort that would equal West's St. Peter's for handsome foliage in the autumn. The red in the leaves is deeper and freely produced in both large and small ones. All gardeners who are anxious to have plenty of such foliage should make room for this variety in one of the late vineries, as it is a late Grape of good quality when well grown. On our sandy soil Gros Guillaume always colours well, the red running in lines up the ribs of the leaf, but I do not consider this Grape worth its room, as the flavour is at best only indifferent. It is scarcely fit to be compared to West's St. Peter's in either fruit or foliage. Black Alicante produces a large percentage of handsome foliage, not so deeply marked with red as the preceding, but covered with small blotches of red. Of late years these markings have been more pronounced, which I attribute to increased applications of potash. The same effect has been observed in Gros Colman, but why it is so much more apparent in some Vines than others by their side is a question that I cannot fathom. Another grand variety with beautiful light red foliage in a late house is Madresfield Court, every leaf being more or less tinted. As previously stated, the soil may have something to do with the colouring, especially as regards one or two of the last named, and manuring with chemical compounds may also bear on the matter, but if I had to plant a Vine

to produce both good fruit and foliage for decoration, I should rely on West's St. Peter's with a certainty of its answering expectations.

W. G. C.

### SHOULD VINE RODS BE SCRAPED?

VERY many gardeners would unhesitatingly answer this question in the negative, and so should I not so very long ago. Now, if asked the question, a more cautious reply would be given: in fact, the answer would be, It all depends upon circumstances. Personally, I have never advocated hard scraping, nor any extreme measure of the kind, but, on the contrary, have favoured the practice of reserving as much of Nature's covering as possible, without, however, going to the length of wholly avoiding touching the bark. It has been my misfortune to have mealy bug to contend with. In order to get rid of this disgusting pest I have been obliged to remove much of the loose bark and scaly pieces about the joints of Vine rods, or otherwise no amount of scrubbing with hot soapy water and no insecticide strong enough to destroy bug or its progeny would be of any avail. That, however, was very different from skinning and scraping the rods, the knife in some cases actually cutting into the inner layer. This, accompanied by addressing of some home-made mixture, or worse still petroleum in some form, is almost certain to have a paralysing effect upon the Vines, the rods breaking badly and also failing to make any further real progress. These much-skinned rods seem to shrink with age, and shanking of berries is only one of the evils attending this extreme practice. One set of rods that came under my care had been thus badly treated years before I saw them, and they had never formed any fresh layers of protecting bark, nor had they attained to half the dimensions they ought to have reached at their age. Nothing short of a complete change of rods, young ones taking the place of the old ones, proved of any avail against shanking, and in about six years the former were as large as the old ones, the age of which no one could determine. In a neighbouring garden the Vines stood out in strong contrast to these. Such extraordinary stems and rods of the same age were rarely if ever seen, and the gardener in charge was very proud of them and their produce, as well he might be. Much of the vigour and grand appearance of the rods was attributed to the fact that they had never been skinned nor even cleaned in any way, the bark actually hanging loosely at places, and being of an extraordinary thickness generally. That gardener would have laughed derisively had I or anyone else insisted that the time might come when even he would find it necessary to clear his rods of much of the outer or old bark, or otherwise fail to produce high-class Grapes in quantity. Yet that time has come, though not in the case of the Vines already alluded to or in the same garden. In the fresh locality the position was much hotter, the soil much lighter, and the trees in the open generally were usually more infested with insect pests than is the case in cooler localities. Red spider soon proved a great scourge, and in spite of sponging the leaves repeatedly, sulphuring the hot-water pipes, changing the surface soil, and frequently drenching the borders, this pest gradually gained the upper hand, the first broods appearing almost simultaneously with the young leaves. After vainly contending against this tenacious enemy, my friend has been obliged to change his ideas and practices with regard to cleaning the stems and rods. Last year they were skinned moderately hard and red spider removed wholesale with the bark, this being followed with a dressing of Gishurst compound mixed with clayey water. It was hoped that enough had been done to get rid of, or at any rate to check the attacks of red spider, but the remedy was only partial. This winter the bark has been taken off still more closely and red spider again found hidden in shoals, and those Vines are actually and of necessity being scraped very hard with a view to clearing out every pos-

sible lurking place. Scrubbing with hot soapy water and a dressing in which flowers of sulphur is freely used follow upon the cleaning, while lay is being very freely added to the border with a view to rendering this far more retentive of moisture than formerly. A more striking instance of the necessity for a change of front I never met with, and, to my friend's credit, he makes no attempt to excuse himself for having at one time held to the opinion and preached the doctrine of the wisdom of letting Nature have its proper course. So long as leaving the whole of the bark on the rods is not the means of creating trouble in the shape of insect attack, by all means let the natural covering of the rods alone; but when the day comes that the bark must be sacrificed, or else the value of the crops will be very greatly lessened, there should be no hesitation as to which course to pursue. It does not matter much if the rods do in time fail to do their work properly, as they are very easily replaced by young ones, and the change may be advantageous in various ways.

W. L.

### NOTES ON PEARS.

IT would be well if more readers of THE GARDEN would do as "Southron" has done, and give some account of the ripening of the different varieties of Pears, &c., from walls, pyramids, and other positions. "Southron's" lot is evidently cast in some favourable position in the southern districts of England. A gardener in Kent, Surrey, Essex, Sussex, &c., has altogether a very great advantage over those placed in more northern districts. In Essex at least, near Ilford, about seven or eight miles east of London, I was much favoured last year. For instance, during the severe visitation of frost in May, when some gardeners in Surrey and Kent had to contend with 10 to 12 of frost, I had 1° only; consequently no blossoms were touched, nor any leaves injured. I fancy the thorough drainage and good cultivation of the land upon which the trees are planted have something to do with their liability to suffer from the effects of frost, and even to a greater extent in improving the quality of the fruit. To what extent good cultivation might influence the time of ripening of the fruit I am not prepared to say. I can confirm to some extent the experience of "Southron" as to the effect of wall culture on some Pears. I grow that best of all Pears, Doyenné du Comice, planted out in the open garden, and also planted against a wall with a southern aspect. The pyramid trees in the open are grafted on the Quince, the wall trees on the Pear stock. The wall trees produce very much larger fruit, but, what is remarkable, it was later in ripening and not nearly equal in flavour to the smaller fruit gathered in the open garden. Josephine de Malines I have never grown on the wall, but have obtained splendid fruit from pot trees grown in the orchard house. It is also grown on the Quince as a pyramid in the open garden. The trees bore rather too much fruit this year; consequently it was neither large nor first-rate as regards quality. The fruit ripened early for that variety, as I had not a single fruit left at Christmas which was not decayed at the centre. I gave up the culture of Beurré Rance even when double grafted, as recommended by a famous fruit grower, the fruit never being good enough. Beurré d'Arenberg is a free-bearing Pear of medium size; I rather like it as a pyramid on the Quince. This season it ripened as Beurré Superfin and Doyenné du Comice went out, and it does not seem decay at the core like some others. I like Pitmaston Duchess to last as long as possible. There is nothing to boast about as regards flavour, but the fruit is juicy and of fair quality. I have been informed that it is one of the most profitable Pears for market.

It is certainly not more than second-rate for flavour, but the large size of the fruit, the noble appearance of the trees when in full bearing, and the almost certain prospects of a crop annually tell in its favour. It does best on the Pear stock. I pick the fruit at three different periods and at intervals of about ten days. Brockworth Park as a pyramid on the Pear stock has done good service for the past fifteen years; it has also the merit of producing large handsome fruit. Louise Bonne of Jersey does not seem to hold the high position it did twenty-five years ago, when Mr. G. F. Wilson used to produce such splendid specimens from his pot trees. It does best at any rate on free soil when worked on the Quince, but I find even on medium clay soils the trees make but poor growths on the Quince, and if the soil is clayey, certainly they ought to be on the free stock. *Beurré Hardy* and *Beurré d'Amanlis* have gradually lost their popularity; in fact, any Pears ripening with *Beurré Superfin* and *Doyenné du Comice* are at a great disadvantage. *Williams' Bon Chrétien* is best as a pyramid on the Quince; it is not worth a wall, but it will ever be grown for its earliness, and the flavour is fairly good if the fruit is not allowed to hang too long upon the trees. I am not sure whether *Uvedale's St. Germain* and *Catillac* are the best kitchen Pears; *Verulam* is a better cooking Pear than either. *Bellissime d'Hiver* is a good cooking Pear. *Directeur Alphan* I bought when it first came out, expecting it to be a good late Pear, ripening in March, but it has never yet come in for dessert, although an excellent kind for cooking.

I have but little experience of the newer Pears. Conference and others of the English-raised varieties seem to have been sufficiently tested, and it would be interesting to know how they have done in different soils and various districts. I notice another variety alluded to at p. 2 which certainly ought to be in every collection—*Marie Louise*, but I have never been able to obtain good fruits from trees in the open garden, but wall fruit is always excellent. The best *Jargonelles* this year, or indeed in any season, I obtained from a wall with a northern aspect. The fruit from standard trees is of small size, but of very good quality. *Jargonelle* when grown on a wall in the south-eastern districts of Scotland surpasses all Pears.

As to the reason why certain Pears are inferior one season and of good quality the next, something, perhaps a great deal, depends upon the season, but something also on the culture. Some persons cannot be induced to drain the ground as it ought to be, nor can they see the value of trenching some soils or bastard trenching others. When the ground is waterlogged for four or five months of the year the temperature is lowered to a greater extent than some people are aware of. Draining raises the temperature and aerates the soil. Another great point in culture is to encourage the roots to come near the surface by summer mulchings and working the hoe well over the roots early in the year. It has been proved that the variation of temperature in the soil is from 61° in summer 6 inches below the surface to 44° at the depth of 3 feet; between these temperatures it was 57° at 9 inches and 50° at 18 inches deep. We can cure canker by draining the soil and raising the roots up to this surface warmth, as I proved over and over again when all superficial remedies had failed. Fungoid growths of various kinds may often be traced to undrained soils and bad cultivation. A healthy tree is not so likely to suffer as one which has become enfeebled by bad culture, and when disease appears upon the leaves or

fruits superficial remedies are applied, while the root of the evil is untouched. Another evil to be avoided by those who would have healthy trees and good fruit is not to purchase badly cultivated trees to begin with. Many persons go to the dealer who will sell for least money, and the inexperienced amateur is often deceived by the appearance of the trees, which may have made plenty of strong shoots owing to their growing too long in one position. When such trees are lifted, or rather torn out of the ground, there are scarcely any fibrous roots, and the thick main roots are usually torn and broken badly. Many of such trees die, and those that live take years to recover, so that this supposed economy of buying in the cheapest market proves to be the most expensive in the end. My advice is, purchase the best trees to begin with; see that a good foundation is laid by well preparing the ground; plant the trees well, and attend to their subsequent culture through the summer months. J. DOUGLAS.

**Lady Downe's Seedling Grape.**—I was glad to see Mr. Douglas (p. 1) recommending this excellent Grape. Owing to its modest appearance as compared with more showy varieties, it is not so much planted as its merits deserve. As a market Grape it is not to be compared with *Gros Colman*, but in private gardens the latter ought not to find a place. Lady Downe's will produce the size of bunch specially adapted for dessert, with a crispness and flavour all its own, and particularly agreeable to the palate. I think the tide of opinion is beginning to turn in favour of higher quality in fruit, as demands have been very good this season for Grapes of good flavour.—W. G. C.

**Melons.**—The small green and scarlet-fleshed Melons mainly grown in this country are all very well in their way, but they are a costly luxury, and only suitable for large gardens where all the appliances are first-rate. In small places, if the fruit can be raised at all, the family may get a mouthful of it at a cost of a pound or so. The large field Melons of the south of France are grown with the help of hotbeds right up to the neighbourhood of Boulogne. These large fruits would surely be much more satisfactory and give a better and more appreciative return in ordinary gardens in this country. The fruit may not be so delicate in flavour as our choicest tender kinds, but it is nevertheless delicious when ripe, and a family can make a meal of one if so disposed. Any one who can grow Cucumbers could apparently grow these Melons. Failing a supply of the seeds from our usual seedsmen, a stock can be easily got by buying a Melon.—J. I. R.

**Apple Barnack Beauty.**—The question is frequently asked why fruit growers, especially those who grow for market, do not plant more late Apples which they could sell at satisfactory prices. In the future I believe that more late varieties of Apples will be planted, as so many growers have planted comparatively early sorts, that when they attain a sufficient size to bear good crops the markets will be glutted, and only those men who grow the finest fruit and carefully pack it will be able to obtain high prices, and even those will be lowered by the mass of Apples put on the market. An Apple that I feel sure will prove a favourite with planters in the future is *Barnack Beauty*; the fruit is of nice size, beautifully coloured on the sunny side, heavy and firm, and will keep perfectly sound into May or later if the seasons have been favourable for well ripening. Even in a season like the past one, in which Apples have kept very badly, some varieties rotting in a wholesale manner, scarcely a fruit of the above has decayed. I have not grown *Barnack Beauty* yet as a standard, but I believe it would answer admirably, as the growth is strong, short-jointed, and upright. As a bush tree it is all that could be desired both on the Crab and Paradise stocks, and commences to crop freely the

second year after planting, being as free as *Lane's Prince Albert* in that respect on our light soil. Its upright growth renders it very suitable for growing in bush form, as it does not require so much room as those more diffuse in habit. The trees if planted at 9 feet apart each way will not become crowded for a number of years if properly pruned and otherwise carefully attended to. This Apple is not only likely to prove an acquisition to market men, but also to private gardeners, who generally have none too many varieties that will keep up the supply late in the spring. That able fruit grower, Mr. Woodward, of Barham Court Gardens, has a very high opinion of *Barnack Beauty*, as it does remarkably well with him in Kent as well as with me in Herefordshire.—G. C. R.

**Mistakes in gardening.**—Mr. Douglas probably has good cause for asserting (January 5, p. 2) that an over-dry condition of the soil "is a fertile source of cracking in Grapes." Possibly he may at some time have had an unpleasant experience similar to that recorded by me. We may, however, be consoled by the fact that the most skilful gardeners are liable to err. Here is a case in point. One of the most noted London market growers had about 1000 Fuchsias coming on for early bloom. Wishing to get them along quickly, he ordered the man in charge to give them a top-dressing of artificial manure. The man thought the plants were hardly forward enough to take it, but was over-ruled by his employer. The result was most disastrous, and instead of these plants being worth 12s. per dozen, they were not worth so many pence. This was a grave error, and one which Mr. Douglas would probably say no good gardener would have committed. I should, however, be sorry to make such an assertion, for no more than "one swallow does not make a summer" does one failure make a man a bad gardener.—J. C. B.

#### UNFRUITFUL TREES.

If the greater portion of fruit trees grown in this country only produced half a crop annually, there would be nearly or quite enough to meet all our requirements, while if they actually bore full crops in years of plenty, then there would be great gluts and much wasted fruit. As it happens, there are great numbers of trees that do not by any chance bear a good crop, and not a few might be termed positively barren. In some instances this unfruitfulness is traceable to faulty treatment of either the branches or roots, but in others it is very difficult to determine what is wrong. More often than not, however, it may be attributed to the worn-out state of both the trees and the borders, and, according to what I have seen lately, it is in town and suburban gardens where this is most apparent. Those in charge cannot, as a rule, be accused of neglecting the trees, but their efforts have been ill-directed. They commence by allowing the trees to assume all manner of forms, while the laterals or spurs are rarely shortened back hard enough for the walls to afford an appreciable amount of warmth or protection. Instead of the spurs standing out from 6 inches to 12 inches from the walls, they ought really to be almost close up to them, or say not more than 3 inches away. Those long, ugly spurs on Apricots, Plums, and Pears rarely produce fruit freely, or if they do, the quality is never what it ought to be. If fruit can be grown 'as well or, perhaps, better in the open than on the so-called wall trees, why go to the great expense of constructing garden walls? The latter are certainly of service, inasmuch as they shut out all intruders, but as good vegetables can be grown without their aid as with. The same, however, cannot be said of fruit, as that grown on properly managed trees against walls will always surpass any of the same kind

or variety grown quite in the open. The most ought then to be made of every inch of wall space. Instead of keeping trees year after year in the hope they will eventually produce remunerative crops of fruit, but which never come, the better plan would be to root a few of them out every season, their places being filled with young trees of varieties of known all-round excellence. Exceptions may be made in favour of trees that are constantly growing most vigorously, as the chances are these may soon receive a check sufficient to bring them into a more productive state, or this can also be effected by root-pruning. Giving a tree its head, that is to say, allowing the branches a far greater spread than formerly, and, in particular, avoiding shortening the leading growths, is a good way out of the difficulty; but too often walls surrounding small gardens are less than 10 feet high, and the trees have to be pruned harder than is good for them accordingly. Whoever saw a tree of Jargonelle Pear cropping freely against a low wall? To see this delicious variety at its best the tree must have plenty of head room, the front or sunny end of a dwelling-house suiting it admirably. Other varieties of Pears, and also Plums, generally succeed remarkably well under similar conditions, a freely-grown, irregular fan-shaped Plum tree frequently producing enormous crops of fine fruit. Let the trees then cover as much wall space as possible, but do not allow them to form heads above a wall, as these soon rob all the rest of the tree of their share of food supply, and much impoverished branches never yet produced good crops of fruit. Excessive vigour must not be met by light pruning, as far as the lateral shoots are concerned, spurring these back to within 1 inch or so of their starting point being imperative for reasons already given, and the remedy (root-pruning) has also been alluded to. When, however, the trees are unproductive, owing to their weakly impoverished condition, something ought to be done in the way of restoring them to a more vigorous habit of growth. In many instances (I am still thinking of town, suburban and other small gardens) the trees, or others before them, have so long occupied the same site without any attempt being made to restore any portion of the fertility the roots have drawn out of the soil, that it is nothing to be surprised at if the occupants simply dwindle away, for that is what it amounts to, thousands of trees being at the present time in a half-dead state. What is wanted is a thorough change of soil, and if fresh fibrous loam or the best portion of the top spit of good pasture land could be had, with perhaps some charred soil and mortar rubbish added, nothing would better suit the trees. Unfortunately, very few gardeners in charge of small places can get enough of this for their Vines and potting even, and supplying it to the ordinary wall trees is out of the question. The next best thing would be the substitution of good kitchen garden soil, or any in which few or no tree roots are found for the old border soil. It is not merely the surface soil that should be used, but in many cases the addition of the next 3 inches of that underneath would greatly improve the mass. Naturally, soils vary largely in their composition, not a little depending upon the way they have been treated during the past few years. According to my experience, small gardens are rarely trenched, and, in fact, many of them are only very slightly dug. Then, again, lime is strange to most of them, and its use at the rate of one half-bushel to the rod has been known to work wonders where used for the first time within the memory of those in charge. The mixture of lime, or, better still, mortar

rubbish freely, as well as of good subsoil, is most desirable for fruit trees, while if the soil is naturally poor some good solid manure may be added, and pulverised clay would greatly improve the character of the lighter or non-retentive soils. All this is suggested with a view to showing that it is possible for energetic men to grow fruit without so many loads of fresh loam for their borders. The latter is desirable, but not indispensable. Where young trees take the place of old ones, they ought to have wholly fresh soil, or compost as suggested, to root in, and not merely a small quantity; while if older trees are to be resuscitated, a good-sized trench should be opened in front of them at a distance of 4 feet or rather more from the stems, some of the roots traced out to nearer the trees, these latter pruned and then relaid, and the trench refilled with fresh compost. Some of the surface soil ought also to be forked away till the roots are found, and this also be replaced with fresh soil. Not much alteration for the better would be apparent during the first season following upon root "doctoring," but the fresh soil would be promoting and sustaining the spread of roots and the formation of root-fibres, and this would not go on long without a corresponding improvement in the top growth and productiveness of the trees. Much in many cases might be done by baring the top roots to a distance of 4 feet from the walls, surfacing heavily with good half-decayed manure and covering this with soil. I have known this greatly benefit Pear trees that previously had failed repeatedly to produce presentable fruit. Watering during the winter whenever there is no frost in the ground with strong liquid manure, such as the drainings from farmyards, stables, and piggeries, only diluting where little water runs into the cesspools, is a very simple and inexpensive way of enriching a border, and cottagers whom I have induced to try this remedy for starved, unproductive trees have had good reasons for being grateful for the suggestion. Unfruitful

TREES IN THE OPEN

are also far too plentiful. Espalier-trained and cordons may be treated much as advised in the case of trees against walls, not a few of the former proving little better than cumberers of the ground. Some of them are suffering from lack of food at the roots, but the great majority are either deriving more than they require from ground about them that has been heavily manured for vegetables, or else are being driven to root deeply, owing to a reckless use of the spade close up to the stems, excessive top-growth being the consequence in either case. Root-lifting and pruning and more rational treatment afterwards are the remedies for this state of affairs. Cordons badly managed are the least productive of all trees at any rate they produce little else than rank growth. Unless these are lifted and root-pruned every second or third year they cannot often be kept from forming too much wood, and in numerous instances might well have their trained branches cut away and the strong central growths allowed to grow naturally and freely, productive bushes or pyramids resulting in the course of three or four years. Those standards, pyramids and bushes that fail to bear fruit owing to their excessively vigorous growth ought for the next two or three seasons to be much more lightly pruned than formerly, those in charge contenting themselves with thinning out young growths where crowded, leaving those best placed to their full length. If shortened, however lightly, little else but wood-growth at the ends will result; whereas if left to their full length there

is every likelihood of fruit-buds forming along their entire length. Those standards, pyramids and bushes that fail to bear satisfactorily, owing to their stunted state, should be assisted at the roots, much as advised in the case of starvelings against walls, liquid manure in particular being desirable for any too large to be easily partially lifted and given a liberal supply of fresh compost at the roots. Chemical manures wash down readily into and are absorbed by cultivated ground, and a dressing of 2½ lbs. of superphosphate of lime mixed with 1½ lbs. of nitrate of soda to every square rod of ground occupied by the fruit tree roots would soon benefit the trees, greatly improving the quality of what fruit does form and promoting more vigorous wood growth. It is the latter that is required to put new life into old trees, and if a good sprinkling of shoots can be forced out of any that have previously failed to grow satisfactorily, this will be found a step in the right direction. Either leave such shoots to their full length or else (in the case of trained trees) cut away about one-half. Eventually these young branches should take the place of some of the worn-out older ones. SELWOOD.

**Dry fruit borders.**—I have this season had occasion to lift a number of young fruit trees planted four years ago, and was surprised to find the soil at 2 feet from the surface quite dry. Doubtless the drought of 1893 in many soils caused a lot of dropping of fruit last season, also small fruit. In my case there was a heavy mulch of decayed manure, the trees were well watered twice a week, and yet the soil was dust-dry. I admit the border was sloping and the trees vigorous, being cordon Pears, but one would scarcely think after the excessive rainfall last year such a state of things would exist. I noted the failure of some large Morello Cherries last season. There was plenty of fruit, but it was very small. On removing the soil between the trees it was equally dry. These trees are at the back of fruit houses and not watered much, being on a north wall, but even here the rainfall had not got under the large mass of fibrous roots.—G. W.

**Flavour in Pears.**—I was much interested in the observations of "Southron" (p. 2) on the premature ripening and flavour of Pears. Although not an advocate for planting any variety of Pear away from the influence of walls, I quite agree that the flavour of many varieties is much improved by growing the trees in the open. Bauré Rance and Josephine de Malines, if grown in the open, never get beyond the tough stage; grown on a western aspect they are not much better. Such early varieties, however, as Williams' Bon Chrétien, Bauré d'Amanlis, Mme. Treve, and Louise Bonne of Jersey are decidedly better in flavour when grown in the open, a freer circulation of air and more direct sunshine reaching the fruits. Such varieties as I have named, on account of their earliness, are very often planted against walls with an eastern aspect. The trees crop freely, and the fruit also grows to a good size, but this is no criterion that the flavour is equally satisfactory. Marie Louise with me is too tender for growing in the open, as also is Bauré Supertin. Not a mile away the varieties named succeed admirably, but the soil, overlying the old red sandstone, is much warmer and lighter, the position also being lower.—Y. A. H.

**Hunt's Tawny Nectarine.**—I think it would be difficult to find a better Nectarine for early forcing than this old variety. True, it is not so large as many, but it is a never-failing cropper and possesses a hardy constitution. I have heard it said that it is liable to mildew, but I have never found this to be the case. The flavour is average, the flesh yellow, and the outward appearance similar to that of Humboldt and Pine-apple. There is a tree at Guntton which has been forced for many years. D. T. Fish referred to it in THE GARDEN some years ago, and in spite of the intro-

duction of so many newer and larger varieties. Hunt's Tawny is still retained. Were I furnishing an early house of Peaches and Nectarines I should certainly include Hunt's Tawny.—J. C.

**Peach Desse Tardive.**—My experience of this is that it is a very uncertain variety, although large and, for a late Peach, of good flavour. It is not altogether a new Peach, as I first saw it some twenty years ago in the gardens at Coombe Lodge, Winkley, Essex. It grew on a back wall of a lean-to house and produced fruit in plenty, of enormous size and extra good appearance. Since then I have seen it in various places, but never in a satisfactory condition. It is grown at Gunton and Bickling, but does not, I think, crop well. I had a healthy tree under glass for five years, but have now rooted it up.—C. H. N.

#### NOTES ON GRAPES.

THE leading article by Mr. J. Douglas on p. 1 (Jan. 5) will have been read with interest by those who have to produce Grapes for home consumption or the market, and few, if any, will be found to differ from his opinion respecting quality and appearance as affecting market and home consumption. I could not help, however, being struck with the decidedly inferior position Alicante holds in his estimation as regards quality and the limited assortment advised for a large establishment, and I venture to think, whether rightly or wrongly, that there are not so many large gardens in which so few are represented as Mr. Douglas advises. If Mrs. Pince could be produced in such perfection as was noticed at the great Crystal Palace fruit show last autumn with the same certainty as Alicante, there would not be any doubt about its value for any purpose, but, most unfortunately, it is seldom seen in such perfection, and it has a decidedly bad reputation among growers generally by reason of its indifferent colour. Mr. Young, of Abberley Hall, is, I believe, among the few who can claim the secret of growing Mrs. Pince Muscat to perfection. I was once shown a photograph of some noble bunches of this Grape grown by Mr. Young, and I remember on being asked what I should consider them to be, remarking that I should suppose them to be good Alicante, such bunches, colour, and berries I had never before seen represented in Mrs. Pince. Those referred to at the Palace show last autumn were, judging from memory, very similar to Mr. Young's, the bunches, berries, and particularly the colour being especially fine. No doubt Mr. Douglas and Mr. Young have both discoursed on the treatment of the Vine in question in THE GARDEN, but to new readers the "secrets" of producing perfect examples would be especially valuable, and possibly to older readers too, for there are without doubt a great many who for some reason or other fail to make a reputation by growing it imperfectly. In its usual "foxy" skin it does not look very tempting in appearance, and where this is so much studied, Alicante as well as Gros Colman displace it. There may be nothing singular in it, but I think it is a fact that gardeners' ideas are moulded very much by the likes and dislikes of their employers, on these two points in particular—appearance and quality—and I cannot help thinking that Mr. Douglas has been in touch with those of very superior taste, because it is clearly apparent that quality has a decidedly prominent tendency in the selection of sorts recommended by him in his notes.

For late keeping, Lady Downe's has no rival, and of its quality I have never heard any complaint. Is it possible for Grapes to vary in quality from one season to another—that is,

when given the same treatment and under good culture? A gardener of Grape-growing fame lately remarked to me that his Lady Downe's were really better this year than he can ever remember them before, and I know his are always first class in every respect. The difference is, perhaps, more a question of fancy than reality, yet at the same time the season and minor differences in the matter of treatment might effect a variation. I am, of course, speaking of the comparison at a corresponding date from one season to another. There is usually a standard from which there is loss or gain in keeping, more or less, but it would be interesting to learn the views of other readers on the point. The garden in which Venn's Muscat originated I know very well, and I have heard the late Mr. Sweeting, its raiser, often speak of the favourable impression it created in its earliest days, but the long house built especially for it has ere this been planted with other and more easily grown varieties, as it developed the same trait as in other gardens—stoneless berries and shanking. Venn's Muscat would appear to be gone almost out of cultivation; seldom is the name mentioned or the variety noticed. There is not much doubt of its identity with Muscat Hamburgh, and that which gained for it its name and former reputation is attributable only to the vigour derived from the seedling stage of life. Large sums were offered the raiser for his stock at the time when it was first exhibited, but it was respectfully declined, he having decided to distribute it himself, and a large structure was built purposely for growing it as a market Grape. In one of Mr. Venn's vineries was a Muscat of Alexandria grafted on a Syrian stock, and although the character of the Muscat was perfect as a natural consequence, the flavour was changed, and resembled that of the Syrian. I tasted berries myself from the Vine in question, and have never met with a similar incident. I saw last year two rods of Muscat of Alexandria. One had been inarched on a Lady Downe's and the other on Gros Maroc, and the difference in the crop was very marked, that on Lady Downe's not being nearly so good as on the other. The object in this case was to convert a house planted with a mixed variety into a Muscat house alone, other Vines being Alicante, Black Hamburgh, and Gros Colman. All these were doing particularly well, but were not in such a forward state in fruit bearing as the two first-named. All the Vines were young and wonderfully vigorous, and it was thus the more remarkable that the Muscat was fruiting so indifferently on the Lady Downe's stock.

WILTSHIRE GARDENER.

#### SHORT NOTES.—FRUIT.

**Peach Dymond.**—The late Mr. Wildsmith spoke highly of this Peach for open-air culture. I, too, think it is one of the best Peaches grown. It succeeds here against a west wall, giving a full crop of large, highly coloured fruit of excellent flavour. I always recommend this Peach now when asked as to the best sorts to plant.—E. M.

**Peach Dr. Hogg.**—I am not much surprised to hear that this Peach forces well. Twenty years since I grew it with much satisfaction, having previously heard it well spoken of by a capable fruit grower. The growth is vigorous, the fruit large and richly coloured. In spite of these points in its favour it is not grown so largely as it deserves.—E. M.

**Apple Lane's Prince Albert.**—I was somewhat surprised to find from the remark of "S. W. F." (p. 23) that this variety is liable to canker. It is the first time I have heard the faintest suspicion of such a thing. Here I grow over 100 trees of this Apple and in strong soil, and still there are no signs of canker. Some constitutional element in the soil seems to point strikingly to the cause of canker in Apple trees.—E. M.

## ORCHIDS.

### POTTING ORCHIDS.

ALTHOUGH there are not many Orchids that require repotting now, the busiest time of the year is not far distant, and a good supply of materials should be got in readiness for the purpose. The plants in baskets, on blocks, and in cylinders should be looked over in order to estimate what number and sizes of these will be required, and these should be procured without delay. A good stock of pots of various sizes should also be washed ready for use, as it is bad management to have to wait for pots when the work of repotting should be in full swing. If new pots are to be used, they should be soaked in water for a day beforehand. Much time will be saved by having the Sphagnum Moss picked over and washed ready for use, a good lot of points being reserved for surfacing. The rougher parts may be kept for covering the drainage and for chopping up, to be mixed with the compost for terrestrial Orchids, as Cypripediums and Calanthes. Some dealers now supply Orchid peat ready for use by having all sand and earthy particles removed. This effects a great saving in labour and also in carriage when it has to be sent a long distance by rail. Although rather higher in price, it is for this reason cheaper than buying peat in turves, unless the residue can be used for Rhododendrons or other rough purposes. Terrestrial Orchids such as named above need a good proportion of loam in the compost, and this should be obtained of as fibrous a character as possible, and have most of the fine soil sifted out in the same manner as the peat. These, with a stock of clean crocks and charcoal broken to various sizes, will be the chief requisites for Orchid potting. Sand I have not mentioned, as I think it very bad for the great majority of Orchids, and one that may easily be dispensed with for any. With regard to the quantity of each material required, this will depend upon the class of Orchids to be potted. For the purpose of this note Orchids may be roughly divided into three groups. The first would be the distichous-leaved plants with upright stems, as Aerides, Saccolabium, and Vandas. None of these show any great liking for peat, but take well to layers of living Sphagnum with charcoal or potsberds freely intermixed to ensure aération and prevent the too rapid decay and consequent souring of the mass. The second—and this constitutes by far the majority of Orchids in general cultivation—is the pseudo-bulbous division of epiphytes, as Cattleyas, Dendrobies, Odontoglots, and a host of others. A mixture of peat and Sphagnum will be the basis of the compost for all these, the quantities of each varying a little according to the habit and liking of the individual species. The third group would consist of terrestrial Orchids and those which, though naturally epiphytal, are found under cultivation to thrive best in a compost similar to that used for the terrestrial group. This, as mentioned above, will consist partly of fibrous loam, with peat and chopped Sphagnum added in varying quantities. From the above an idea may be formed of the proportionate amount of each requisite, and if these are all prepared, together with a few neat stakes and labels during the dull season, the pressure of work later on will be considerably lessened.

H. R.

**Dendrobium Wardianum.**—This well-known Orchid is among the most beautiful and showy now in flower. The Burmese form grows much more strongly than the type, and also appears to flower earlier. [This is known as *D. Wardianum*

Lowi and also as *giganteum*. The flowers of the best varieties are 5 inches across and produced upon the leafless pseudo-bulbs of the previous year's growth in twos and threes, as many as thirty being sometimes produced upon a single stem. In the culture of this species the chief point is to get the growth well ripened as early as possible in autumn and to give the plants a decided period of rest before being introduced again to heat. Large pots are not required, as the more crowded the roots are the better the plants thrive. I remember being very much struck by a plant some years ago grown by Mr. E. S. Cole when gardener at Woodside, Stoke Bishop. This had several pseudo-bulbs at least 1 yard in length, and was growing in a piece of cocoa-nut shell about 2½ inches or 3 inches across, the natural apertures in the shell allowing the surplus water to escape. At this time of the year, when the young growths are appearing at the base of the pseudo-bulbs, great care must be exercised in watering, or the young shoots will damp off wholesale. On dull cold days the plants will be much better without any water, giving a good soaking when the weather is fine and allowing them to get quite dry before being again watered. They must be allowed to grow quite naturally and not be staked or tied in any way, or the beauty of the plants when in flower will be spoilt.—H. R.

**Cypripedium callosum superbum.**—One of the best forms of this fine *Cypripedium* I lately noted in bloom. The flower is borne upon an erect scape about a foot in height, and is well set off by the finely tessellated, deep green foliage. In this variety the dorsal sepal is large and very broad, pure white over two-thirds of its surface, with long and short veins of a rich vinous purple colour. The petals are broad, heavily shaded with purplish rose, and spotted on the upper margins only, with several large blackish warts. The typical form of this species was introduced from Siam ten years ago by M. Regnier, of Paris, and is a decided acquisition. It flowers during the early months of the year, and equals, and in some instances surpasses, in the size and beauty of the dorsal sepal any other kind yet seen.—W.

**Cypripedium Lathamianum** is a very pretty hybrid, raised by Mr. Latham, curator of the Birmingham Botanic Gardens, between *C. Spicerianum* and *C. villosum*. A flower of this is sent by "C. W.," but it appears to me to be a very pale variety, and might be said to be near the *C. Leo* raised by Mr. Lee, and which may be described as a very pale form of this kind. I recently noticed in Messrs. Peed and Sons' nurseries at Tulse Hill a very nice variety, the dark purple line in the upper sepal as well as the central stripe down each petal being very pronounced.—G.

**Oncidium tigrinum** (*W. Macbr.*)—From this correspondent comes a bloom of this Orchid. He says he bought it under the name of *Oncidium Barkeri*, and is disappointed that it has turned out different from his expectations. Both these names are identical, and it is rarely that it is called at the present day *O. Barkeri*, it being too well known by its proper name. This, one of the finest Mexican Orchids we have, was discovered early in the present century and described in 1825 as *O. tigrinum*, but upon its being introduced in a living state about 1840 it received the name of *O. Barkeri* from Dr. Lindley, who did not identify it with the herbarium specimens.—W.

**Lælia anceps.**—From Mr. James Cypher, of the Queen's Road Nurseries, Cheltenham, comes a box containing some beautiful white varieties of *Lælia anceps*. Amongst them the following kinds are decidedly worthy of notice: *L. a. alba*, a flower of fine form, being entirely pure white, excepting the yellow crest on the lip and a few purple lines on the interior of the side lobes; *L. a. Hilliana*, a very distinct form with white sepals and petals, the side lobes of the lip flushed and margined with amethyst-purple, whilst the acute front lobe is bright purple at the tip, and with a large orange-yellow disc. *L. a. Percivaliana* is a very delicate

and pretty kind, the lip being pale rose and the other segments pure white. The best flower in the whole was one unnamed. This measured about 5 inches across and much resembled the rare *L. a. Dawsoni* both in shape and markings. The sepals and petals are of the purest white, the latter very broad; the side lobes of the lip large, beautifully expanded and streaked with purple lines; whilst the front lobe is of a bright rich purple, margined with white. This is one of the finest varieties I have seen. These white forms of this popular *Lælia* are amongst the most beautiful kinds we have, and require a somewhat warmer temperature than the typical and dark-coloured varieties.—H.

**Odontoglossum bictonense.**—It appears rather late in the season for this interesting plant to be in bloom, but some flowers have just come to hand from "C. W." The usual time for this species to bloom is from about September until the end of November. The flowers before me are very small, and I would advise "C. W." not to allow large spikes to remain upon newly-imported plants, as this materially weakens the constitution of the plant and very often kills it. A far better plan is to allow only one or two flowers to develop upon the first spike produced, and as soon as these are fully open, so that the variety may be determined, the spike should be removed. This will enable all the strength to be thrown into the plant, it thus becoming better established before flowering next season. *O. bictonense* is a native of Guatemala, and was first introduced into cultivation just sixty years ago. The flowers, borne upon an erect spike, are yellowish-green, blotched with brown, the lip pale rose. This is the typical form, but many varieties have since appeared, among them being *roseum*, with a deep rose lip, the other segments reddish-brown; *album*, with brownish segments and a clear white lip; and *sulphureum*, with yellow sepals and petals and a white lip.—W.

#### ODONTOGLOSSUM PULCHELLUM.

This pretty species appears to have been scarce for many years after its introduction, which was about fifty-four years ago. It was first discovered by Mr. Ure-Skinner in Guatemala, and deserves a place in every collection. The cultivation of this plant is by no means difficult, as it is found in a wild state at considerable elevation, and will therefore thrive with the other *Odontoglossums* in the cool house. Whilst the plants are in flower, which will be during the present and the next two or three months, it will be found beneficial to remove them to a drier atmosphere, where the blooms will continue longer in perfection. *O. pulchellum* should be potted in fibrous peat and Sphagnum Moss, with good drainage, the plants being well elevated above the rim, and at no time must they be allowed to get dry at the roots. The flowers are borne upon erect scapes, which are longer than the leaves, and the blooms generally number from five to a dozen upon a spike. These are very distinct and very fragrant. The individual flowers appear upside down, that is, the lip is the uppermost portion of the flower. The flowers are pure white, with the exception of the large yellow disc of the lip, where it is finely spotted with reddish crimson. Amongst the importations which have from time to time arrived there have appeared several fine varieties, one being

*O. PULCHELLUM MAJUS*, a decided improvement on the typical form. In this variety the pseudo-bulbs are larger and the plant of more robust growth, the flower-spike also stronger and more thickly set with blooms, which are as large again as in the type. It is also known in our gardens as *O. pulchellum grandiflorum*. During more recent years, however, a still more beautiful variety has appeared, and which is named

*O. PULCHELLUM DORMANIANUM*. This is no doubt the finest form of *O. pulchellum*, a nice specimen of which I recently saw in the collection of the gentleman whose name it bears. The pseudo-bulbs are not so long as in the typical kind and the flowers are much larger, the segments broader even than in the form *majus*.

WM. HUGH GOWER.

**Cattleya speciosissima.**—This fine *Cattleya* belongs to the "labiate" section, and is one of the largest flowering kinds known. It usually produces its blooms during the latter part of the year upon the young growths which may be just completed, and without any decided period of rest; therefore if "W. J. T.'s" plant has not yet shown any signs of flowering he must wait until new bulbs are formed, for it will not bloom from old bulbs. It has been known in our gardens for a number of years, and should be grown in the *Cattleya* house suspended near the light. It is a native of Venezuela, and was first introduced in quantity by Messrs. Low and Co.—W. H. G.

**Cypripedium Vesta.**—This is a cross between *C. Harrisianum* and *C. Spicerianum*. From these two kinds we have several fine hybrids, including *C. Pitcherianum* and its varieties, *C. Adonis*, *C. Savageanum*, and the reverse, *C. Seegerianum*, &c., all of which, however, are totally distinct from *C. Vesta*. This was raised by Mr. Norman in The Firs collection, Laurie Park, Sydenham, *C. Harrisianum* being the seed-bearing parent. It was hybridised in December, 1889, and the seed was sown exactly twelve months later. The foliage is reticulated and much like that of the seed-bearing parent, and the bloom is borne upon an erect stout stem. This is bold, and a charming combination between the two kinds above mentioned. The dorsal sepal is large, pure white, slightly green at the base, where it is shaded rose and has a highly-coloured central line. The petals are very broad, slightly wavy, and measure nearly 5 inches across, with a well-defined mid-line of purple colour, the upper half soft light brown, the lower part light green and finely spotted at the base. The lip is pale green, flushed with brown.—W.

#### SHORT NOTES.—ORCHIDS.

**Dendrobium Dominicanum.**—This is a cross between *D. nobile* and *D. Linawianum*, and intermediate in character. The blooms are mauve-purple at the tips, almost white at the base, the petals of a brighter shade than the sepals, whilst the lip is white, with a maroon-purple disc.—G.

**Dendrobium nobile nobilium** (*Ed. Ingram*).—The flowers to hand under this name are not of this fine variety, but of a good form of the type. The true *D. nobile nobilium* is still a rare plant. The sepals and petals are heavily suffused with rosy purple, deeper towards the tips, whilst the blotch on the lip is intense crimson-maroon.—W.

**Cypripedium insigne.**—It is astonishing what a large quantity of this fine old plant is now grown for cut blooms, a large number of flowers finding their way daily into Covent Garden Market. For decoration of all kinds there is no better kind than this species, for its blooms are of a pleasing shade of yellow, and will last for a considerable time in perfection.—G.

**Cypripedium Goultenianum.**—I recently noticed this pretty hybrid in flower at Sydenham. It is the result of crossing *C. callosum* with *C. Curtisii*, and forms a nice combination. It has a fine dorsal sepal, heavily veined and shaded with bright rose, and long drooping petals, light at the base, but changing to rose at the tips, and spotted with large blackish spots, the lip more resembling that of *C. Curtisii*.—H.

**Calanthe Veitchii.**—A fine display of this charming winter-blooming plant is now to be seen in Messrs. Laing and Sons' nurseries at Forest Hill. The bright rose-coloured flowers, which are produced freely, are very welcome during these dull days, and with a little care a good succession of blooms may be maintained for a considerable time. This fine old hybrid *Calanthe* is of great service where cut blooms are in demand.—W.

### ART IN RELATION TO FLOWER-GARDENING AND GARDEN DESIGN.

THERE is no reason why we should not have true art in the garden, and there is much reason why we should have it. There is no reason why a garden should be ugly, bare, conventional, or stereotyped, though most gardens are so. The word "art" being used in its highest sense here, it may perhaps be well to justify its use. As good a definition of the word as any perhaps is "To see and give form to beautiful things." We see it in its highest expression in Greek sculpture and in the works of the great old masters of painting, and in good landscape painting. But art is of many kinds, and the word is frequently applied in our own time to trifling ornament often overdone. Owing to the loose, "critical" talk of the day, it is not easy for everyone to get hold of the central truth of art, *i.e.*, clear-eyed study and love for Nature rather than invention and the bringing of the "personality" of the artist into the work of which we hear so much. We should understand first of all that the work of the true artist is always marked by its fidelity to Nature. Proof of it may be seen in many places, in our National Gallery and the Louvre; and the greatest art galleries being now open to all, there is little to prevent the simplest person proving what is said here about pictorial art in its highest expression.

But as a number of people unfortunately write much about art in the magazines and papers without having first received any training which enables them to see its laws, there is consequently infinite confusion in many minds about it. One may read book after book and essay after essay about art without being brought a bit nearer to the simple truth. Artists, brush in hand, will urge the false idea that it is not by observing, but by inventing and supplementing that success is arrived at. The strong man must be there certainly, but his true work is to see the whole beauty of the subject and to help us to see it, not to distort it in any way for the sake of making it merely singular. This, it is true, is often done as an easy way to popularity, but in the end it means bad work, and only the good work lasts. Other work may be the fashion for a season, owing to some one quality; but it is soon found out, and we have again to return to the great masters of all ages, who are always distinguished for truth to Nature.

The truth of the thing in all its fulness is almost the whole of the question, but the critics of the day will not take the trouble to see this. Artists, men of education,

and gentlemen write essays on art in which many unmeaning and misused words occur, but in which we may not once meet with the word *truth*. "Realism" and "idealism" are words freely used, and thoroughly bad pictures and examples are shown us as examples of realism when they are only remarkable for leaving out all the refinement, subtlety, truth of tone, and perhaps even the very light and shade in which all things we see are set. They leave out all the refined charms visible to those who look at Nature as well as at pictures, and then condemn the result as "realism." The man who will not take the trouble to see the beauty of the real is sure to go astray in quest of the "ideal."

There are men so blind to the beauty of the things set before their eyes in sky, sea, or earth, that they would seek to idealise the eyes of a beautiful child or the clouds of heaven; while all real students of natural beauty in landscape know that no imagining can come near to the beauty of

*Last expression of carpet gardening at Chicago.*

things seen, art being powerless to seize their full beauty, and the artist has often to let the brush fall in despair. Only a little, indeed, of the beauty that concerns us most—that of the landscape—can be seized for us except by the very greatest masters. Of things visible to us—flower, tree, landscape, sky, or sea—to see the full and every varied beauty is to be saved for ever from any Will-o'-the-wisp of the imaginary. The real is the fullest beauty.

But many people do not judge pictures by Nature, but judge them by pictures, and therefore they miss the subtleties of Nature, and all those delicate facts of light and shade on which all true work so largely depends. Many of them sneer at those who "copy Nature," but the answer to such critics is for ever there in the great work of the great men, be they Greeks, Dutchmen, Italians, French, or English.

It is essential to remember that part of the work of the artist is choice of subject—the selection of beautiful or memorable things, not necessarily the first things that come in his way. The Venus of Milo is from noble

type of woman—not a mean Greek. The horses of the Parthenon are the best types of Eastern breed, full of life and beauty. Great landscape painters, like Crome, Corot, and Turner, seek not ugly things because they are natural, but beautiful combinations of field, and hill, wood, water, tree, and flower, and grass, selecting views which are good in composition, and then waiting for the most beautiful effects of morning, evening, or whatever light suits the chosen subject best, to give us lovely and true pictures! But they work always from faithful study of Nature and from stores of knowledge gathered from her, and that is the only true path for the gardener, all true art being based on her eternal laws. All deviation from the truth of Nature, whether it be from the hands of Greek, Italian, or other artist, though it may pass for a time, is in the end found out and, it may be ages after the artist is dead, classed as *debased* art.

Why need so much be said about art? Because once we see the meaning of true "art" we can have no patience with what is ugly and false in art, and it becomes impossible for us to have the foregrounds of the fairest of cultivated landscape scenery dandied with a flower garden like a coloured lithograph. Many feel the right way from their own sense being true, but others will be better for seeing proofs of what is urged here as to the true source of lasting work in art in the work of the great artists of all time. And we may be as true artists in the garden as anywhere else.

So far we have spoken of the great work of the true artist, which is always distinguished by respect for Nature and by keen study of her. But apart from such we have a great many men who do what is called "decorative" work of a wholly different kind, useful it may be, but still not art in the high sense of delight and study in things as they are. I mean the whole class of decorative artists, who make our carpets, tiles, our curtains, and many other things of the kind. Skill in this way may be considerable without any attention whatever being paid to the greater and the higher art of which we have spoken, that art being concerned with life in all its fulness, the decorative "art" being the adapting of conventional or geometric forms mostly to flat surfaces.

This it is necessary to clearly understand, because for the flower gardener it is everything on which side he stands. Unhappily, our gardeners for ages have suffered at the hands of the decorative artist, who applies his conventional art to the garden, for which it is clearly unfit. Patterns which may be quite right on a flat sur-

face like a carpet or wall paper have been applied a thousand times to the surface of the reluctant earth. We see this in many gardens and in many books; it is, indeed, this adapting of absurd knots and patterns from old books to any surface where a flower garden has to be made that leads to deplorable design—wrong in plan and impossible as an abode for plants. It is so easy for anyone asked for a plan to furnish one of this sort without the slightest knowledge of the life of a garden, the needs of the plants of which should govern the design.

For ages the poor gardener has been troubled by trying to adapt himself to absurdities of this kind of work as regards plan, and for ages the beds in these plans were adorned with flowers in more or less simple and natural ways. But in our own time the same "decorative" idea has come to be carried out in the planting of the beds themselves under the name of "bedding out," carpet bedding, or "mosaic culture," of which, notwithstanding the many changes for the better of recent years, we see so many examples everywhere. In this the beautiful forms of flowers are degraded to the level of crude colour just to make a design and without reference to the form or beauty of the plants. When these tracery gardens were made, often by people without any knowledge of the plants of a garden, they were found to be difficult to plant; hence the desire to do without the gardener altogether and get colour by the use of broken brick, white sand, and painted stone, as at Kensington and various private places in our own day. All such work is wholly wrong and degrading to the art of gardening, and in its extreme expressions is ridiculous, as we see from this illustration of a garden at Chicago made during the past year.

Why are such designs bad and hateful? The good sense of all is the final court of appeal for even artistic things, and to many people these things need not be said, but the stereotyped gardens that abound in many

places show us how much has to be learnt by others. The men whose taste we should respect as judges are those whose life-work it is to study and portray beautiful, natural forms. To these men the modern garden is no more interesting than an oilcloth pattern, because instead of beautiful things we see emphasis given to mere pattern-work and flowers very

rest his eyes on a cottage garden, and may make a beautiful picture of it, because the cottage garden is itself a picture in thousands of cases. Why should the cottage garden be a picture when the gentleman's garden is not? The reason is, that one sees the plants and the vegetation not set out in any offensive, geometrical or conventional plan.

A simple plan is necessary, but in the making of a garden the plan should be subordinate to the living things. Here is an engraving of a very small cottage garden in Oxfordshire to show what is an artistic garden in its simplest expression. There was very little in this beyond the Monthly Rose and a few Pansies and the tree beyond, and yet it was right and beautiful. There are many better in every county in England. May the large gardens be as good in proportion to the money spent upon them and their size as this poor little cottage garden? Most certainly, and many charming gardens described and figured in THE GARDEN prove it; although it is rarely that a large garden possesses anything like the charm of simplicity and directness that many cottage gardens do. But there is no reason why such pictures may not be seen on a larger scale.

The gardener must follow the true artist, however modestly, in his respect for things as they are, in delight in natural form and beauty of flower and tree, if we are to be free from barren geometry, and if our gardens are ever to be true pictures. The gardener has not the strenuous work of eye and hand that the artist has, but he has to choose from ten thousand beautiful living things; to study their nature and adapt them to the soil and conditions that surround him to get the full expression of their

often denuded of their grace of growth and form. Then where shall we seek the artistic garden—one in which Nature is so far allowed to have her way, that nobody is frightened out of the garden or led to abhor it as absolutely an unclean thing? Now, while the artist may be driven from the common garden, he will perhaps go to

beauty; to place them rightly and in right relation to other things, which is a life study in itself, considering the great numbers of the flowers and flowering trees of the world. And as the artist's work is to see for us and preserve in pictures some of the beauty of landscape, tree or flower, so the gardener's should be to keep for us as far as may be,

An English cottage garden. Simplest expression of the beautiful garden.

in the fulness of their natural beauty, the living things themselves.

## KITCHEN GARDEN.

### CELERY CULTURE.

ALTHOUGH a good supply of Celery has always been regarded as indispensable in all private gardens, its importance seems to be more fully realised every year. Formerly Celery was rarely used in a cooked state except in soups, but since its extremely valuable medicinal properties have been discovered it is frequently served up as an ordinary dish. Moreover, where there is plenty of ground and good breadths of Celery can be grown, its frequent use in the dining-room is advantageous to the gardener, enabling him to make the most of other crops, and in periods of severe frost, when winter Broccoli is killed, the use of cooked Celery prevents the too frequent recurrence of ordinary greens on the table. As a rule much very early Celery is a loss rather than otherwise, as if more arrives at maturity, say at the middle of October, than can be used between then and the same time in November, wholesale rotting often occurs, especially with the white varieties, should the weather be wet and foggy; whereas successional rows being still in a growing state are able to assimilate the moisture and so escape the scourge. Some growers sow both their early and main crops of Celery in heat and afterwards prick the seedlings out into shallow boxes similar to those used for Geranium cuttings, but unless for an early row, which can be got out as soon as ready and protected, I do not care for the system. When large quantities of main-crop red varieties are brought forward in boxes and delay in transferring to the trenches (either through inclement weather or press of other work) occurs, the roots of healthy plants become so interwoven, that removal with a fair amount of soil attached becomes impracticable, flagging and a severe check follow, not unfrequently ending in a dogged refusal to grow, or its equivalent—bolting to seed.

The end of March or first week in April is a good time for sowing the seed of the main crop. I prefer raised beds in frames having a due south aspect and a sheltered situation. The soil, which may consist of a fairly rich friable loam previously passed through a coarse sieve and rendered porous by the addition of a little leaf-mould, should be made firm and have a gentle slope towards the sun. Sow broadcast, shallow, and thinly, finally making the surface firm with the back of the rake. Moisten with a fine rose and keep the frame close till the seedlings appear, covering with mats should the nights be cold. As soon as the plants are fit to handle they should be freely thinned, pressing those that are left to develop well into the soil with the finger and thumb in order to make them firm. Free ventilation by day in fine weather and early closing, so as to husband sun-heat, will best conduce to a sturdy growth and hasten on the plants to a transplanting size. Nothing surpasses shallow pits or frames for pricking the plants into, and as Celery enjoys a rich larder, they should be furnished with 8 inches or 9 inches of loamy soil overlying a good thickness of spent manure. Where ordinary frames are not at command, rough home-made ones composed of 12-inch deals and covered with mats at night will answer the purpose, lights being dispensed with. Nine inches between the rows and 4 inches from plant to plant is a suitable

distance, this allowing plenty of room to work in the trowel at lifting time. As the season advances and the plants gain strength, more air will be necessary until at length the lights are entirely removed. The less coddling Celery plants are subjected to the better, this being amply proved in the neighbourhood of Retford, where it is largely grown for market, and where thousands of plants are annually pricked out into sheltered nooks and corners with very little after protection.

In regard to the final trenches, I prefer those holding only one row of plants to those holding two, three, or more, and would always adopt them except where ground was scarce, as, independent of the difficulty of earthing up on the many-rowed system, the flat beds of soil, which in that case cannot be avoided, act as a receptacle for rain water, and in wet winters induce rotting, the reverse of what is the case with single rows earthed up in sharp ridge form and rendered almost rain-proof by the free use of the back of the spade. This I have proved over and over again. Where practicable Celery trenches ought always to be prepared some little time before they are wanted; the soil then has time to settle and holds moisture better. Where this is postponed to actual planting time, the trenches should be well trodden, raked over, and, if necessary, well watered and allowed to stand for a few days. Good spit manure suits Celery well, and when in full growth, about three copious drenchings, first with liquid manure and afterwards with clear water, will work wonders. I am, however, opposed to excessive feeding, as although healthy roots will assimilate almost any quantity of nourishment, the use of blood, night soil, or similar manures produces a rank, sappy growth totally unfit for eating and terribly prone to decay. Except in the case of very early rows wanted for use in September, earthing up ought not to be taken in hand until the plants are three parts grown, otherwise the sticks do not attain to a normal size. All suckers should be drawn away from the base, and if one man only performs the work, each stick should be tightly tied round with bass or soft string to prevent the soil from getting into the hearts. If two men can be spared so much the better, as one can then walk backward and grasp the plant with both hands, while the second man, walking forwards, brings the soil well up to the plants. In regard to the Celery maggot, sprinkling the foliage over with soot and wood ashes during showery weather, or sprinkling first with a rose, may keep the fly from striking it, but when once the mischief has commenced nothing but determined and repeated hand-pickings will conquer it. The common Bracken is the best material for covering the ridges in time of frost, this being less unsightly than straw, and where only a row or two is grown, oiled canvas, now sold at a cheap rate, answers well. With regard to varieties, Sandringham White is hard to beat for early work, but for main crop Wright's Grove White is a grand variety. Of reds, there are many strains almost equally good, but I prefer Leicester Red, this being of first-rate quality. The old Ivory's Nonsuch is a good pink variety.

J. CRAWFORD.

**Trenching.**—Those gardeners who left the work of preparing the soil for the ensuing season's crops until it had recovered somewhat from the heavy rains of autumn have done wisely. It is surprising, given a few weeks of dry weather, how soon the ground will get back to its normal condition after a long spell of wet, and how rapidly work can be caught up. The past week or two

has been singularly favourable for trenching. There have so far been no frosts to interfere with the operation, and now it is found that ground is being very rapidly prepared for crops. As to the benefit to crops of trenching, it seems hardly needful to refer to it at this time of day, yet there are thousands who garden and who are as neglectful of trenching soil as of any essential in garden work. The benefit is indeed immense. How many gardeners of a sort are there who are constantly calling out for more cropping space who could practically double their crop produce did they but regularly and deeply trench ground, as is done in all good gardens. With these an ordinary digging of some 10 inches or 12 inches depth is thought to be ample, simply because it is so much better than ploughing. The addition of some 3 inches more in worked depth of soil every few years until from 30 inches to 36 inches of depth is obtained is eventually productive of wonderful results.—A. D.

**The season and Celery.**—This is one of the best seasons I ever remember for Celery, the heads being heavy, solid, with a crisp and nutty flavour. A few weeks since I noted a correspondent referred to an early batch which had been seriously injured by over-feeding. This is an error of culture which I have previously called attention to. As long as Celery has a fairly rich root-run provided when the plants are first set out, very little manure water or other artificial dressings are seldom needed; certainly not during such a cool and dripping season as we have now passed through. I give the Celery two light dressings of salt, which just give the stimulus needed, the growth being solid and devoid of pithiness. Celery which is over-fed quickly goes to decay. There is now-a-days too much of a tendency to force vegetables into a coarse growth by gorging the roots with liquid manure and surface dressings of artificial manures, and Celery is no exception. On cutting several heads through lately at a Chrysanthemum show to test their quality every one of them had either started to decay or were soft.—A. Y. A.

**A good keeping Onion.**—For many years I have grown Bedfordshire Champion, and have never found a better keeper. I first saw the above variety largely grown for market at Sandy and the district around, and was informed it was the best keeping Onion, even superior to James's Keeping. I have found it so, and for many years have grown none other for late use. I admit it does not attain a huge size without special culture, but for keeping, size is not required. This old, but good form is well worth growing where Onions are required late in the spring.—W. M.

**Cabbage Winnigstadt.**—This is one of the best varieties for autumn use. The greatest difficulty is to get it true. By making two sowings there is no lack of good Cabbage from September to December. The useful St. John Day's Cabbage runs the Winnigstadt very hard for quality and usefulness for autumn cutting. I can also strongly recommend the Winnigstadt for light soils. I have also sown it in July and August for spring cutting, but with such really good spring varieties as Ellam's, there is no need to sow at these dates.—G. W.

**When to dig heavy soils.**—Gardeners who have a heavy soil find it more difficult to select favourable opportunities for digging than those who have sandy soils to deal with. Especially is this noticeable in a season like the present. The moisture from light land drains away quickly, and after a couple of dry days the digging may be proceeded with. But not so on heavy land, as at this period of the year a week or two is needed to bring it into condition for working, and very likely several weeks have to elapse before such an opportunity occurs. It seems good advice to recommend the digging of all heavy land in the autumn so that the winter's frosts and snow can act upon it. Unfortunately, there are heavy soils that cannot be so dealt with even during the most favourable periods for autumn digging. The best period I have found to operate on such heavy soils

is to wait until February is in, and then if a dry period occurs commence digging in earnest. Turn the soil up roughly with digging forks—not spades upon any consideration—and the frosts and drying winds will act upon it, and by the time it is wanted for spring cropping it will work very freely. The result will be a good depth of pulverised soil, which may quickly be prepared for cropping.—KITCHEN GARDENER.

**Tomato cuttings.**—In October I advised the insertion of cuttings of any favourite variety—several in one moderately sized pot—and the wintering of them in an intermediate house close to the glass. These should now be topped and the cuttings inserted singly in very small pots, and plunged in a mild bottom heat in the Cucumbers house. These will soon root, and may then be potted on, finally fruiting them in 9-inch pots. By this system early fruit is obtained, the supply being kept up by spring-sown plants. Seed may now be sown of any hardy prolific variety, two seeds being placed in each  $2\frac{1}{2}$ -inch pot, the strongest plant being retained. Plants that have been bearing fruit throughout the winter may with increasing length of days be fed more liberally, top-dressing being repeated as often as new feeders appear on the surface; attend also to fertilisation at noon on fine days. J. C.

EARLY SEAKALE.

In order to have Seakale fit for use early in the winter the crowns must be well matured and the leaves falling away from them in October. If the leaves have to be dragged from them as they are lifted for forcing we cannot reasonably anticipate a strong early growth. Whether we expect it or not, strong growths are not had from plants thus treated, but, on the contrary, nothing but spindly shoots are forthcoming. As a rule, fresh plantations are formed too late. By starting the plants early there is not only a good prospect of their becoming extra strong, but they also mature earlier, and as a consequence are more suitable for early or hard forcing. The old-fashioned plan of forcing the plants where they are grown with the aid of earthenware or other coverings and hotbeds undoubtedly answered well, and is still practised with good results in many gardens, but it is a slow, rubbishy, and cumbersome proceeding, and is rapidly giving way to that of raising plants thickly, lifting and forcing these in heated houses, including Mushroom houses and pits. It is not contended that such fine produce is had by the newer method as by the old, but far greater quantities of good well-blanching Seakale are forthcoming now-a-days without much trouble. There is, however, room for an extension of the practice, more especially in the direction of growing a thousand plants where less than half that number is now considered sufficient or, rather, has to be enough. Instead of devoting so much garden room to the uncertain crops of Broccoli as formerly, or to Brussels Sprouts, Savoys, and such like, only to spoil half these, owing to their not being sufficiently appreciated in the dining room, why not grow more of a class of vegetables that invariably meet with favour? In the latter category Seakale must be placed.

Now is the time to decide upon taking this step, as it also is the time for commencing the propagation of a fresh stock. According as the roots, or rather plants, are lifted for forcing, they are usually trimmed to admit of packing them thickly in soil in pots, boxes, or beds prior to being forced. This means cutting off a number of clean straight thongs about the size of a man's little finger, and it is these which are most suitable for propagating. They should be cut straight across at the thickest and which is always to be the upper end, and a slanting cut made at the other end, the cuttings not exceeding a length of 5 inches. It is far too soon to trust these in the open ground, but instead of this all should be dibbled in closely into beds of soil in pans or boxes, only just showing above the soil. They can then be stored in a shed or outhouse out of the reach of very severe frosts,

and the soil about them ought to be kept moist. If the present is not a convenient time for placing in boxes, the cuttings should yet be made soon and stored roughly in sand or fine moist soil for a few weeks. By the end of March all should have sprouted and also commenced root action; but if they were put in late or are backward, place them for a few days in a gentle moist heat, and this will bring them forward quickly. When the stock of Lily White was still small I had all the stouter thongs cut from plants that had been forced and made into cuttings, not a few of them being freely split up, and yet all started well in heat. In any case all ought to be hardened off and planted out not later than the second or third week in April, and, the state of the ground permitting, they should be got out at the end of March, an early start, as before hinted, being of the greatest importance. Seakale requires, and should have, a freely-matured, well-worked breadth of ground devoted to it, and this should be selected and prepared at once, as it is very certain the cuttings will not start well in lumpy soil. Plant with a dibber firmly and just deep enough to bury the tops of the cuttings, disposing them from 12 inches to 15 inches apart in rows not less than 18 inches apart. Hand-picking early in the morning is the best remedy in the case of small black slugs attacking the cuttings, and the shoots on the latter ought to be reduced to one in each case, as if more are left to grow, the chances are the crowns will be small. Failures may be made up by transplanting. Should dry weather set in before the plants are well established, give an occasional watering, while surface hoeing will be needed during the early part of the season to keep the ground loose and free of weeds. Raising from cuttings is far better than sowing seed, as seedlings rarely attain a serviceable size in one season.

SELWOOD.

**Huge Onions.**—Some years back it was thought that 1 dozen Onions that weighed 1 dozen lbs. were good. Then Mr. Clarke (Earl Ellesmere's gardener), Mr. Wingrove (Rousham Park), and Mr. Doherty showed Onions, a dozen of which weighed 18 lbs. and 20 lbs. After them came Messrs. Wilkins, Pope, Lye, Kneller, and Bowerman, who have amongst them secured the latest prizes. The weight went up to 24 lbs., 28 lbs., and 30 lbs. Then Mr. Kneller grew a dozen Ailsa Craig 34 lbs., and now last year Mr. Wilkins has topped it with 39 lbs. to the dozen. Messrs. Carter, of High Holborn, showed some bulbs over 4 lbs. each. Messrs. Peter Henderson, of New York, have even eclipsed that. They possess an Onion that has been grown to the following weight: New Mammoth Pompeii, between 4 lbs. and 5 lbs.—A. W. CREWS, *Banbury*.

**Kingsholm Cos Lettuce.**—I have grown the Kingsholm Lettuce for many years. I like it best for summer use, as I find it stands drought better than many of the newer kinds. I was advised some fifteen years ago to give the above variety a trial, and having a poor gravelly soil to deal with had a deal of trouble with Lettuces owing to the plants bolting in hot weather. This variety is, however, free from that defect, and in hot, dry summers is invaluable for its good keeping qualities. It may be described as a white Cos, perfectly solid, with folding leaves, which require no tying, this being a great advantage, as some of the Cos varieties decay badly when tied in wet weather. I have not seen this variety grown much in the London district.—W. M.

**Pea Criterion.**—For the past three seasons I have grown this Pea in quantity, and find it one of the best for second sowing. It may be termed a main-crop variety. I sow it to follow those planted out or sown early on warm, sheltered borders. I have a liking for the old well-known Champion of England Pea when it can be obtained true. Criterion may be termed an earlier form of that variety, but it is larger and partakes much of the character of Ne Plus Ultra in size and colour. Last summer this variety cropped splendidly, and did not suffer from mildew. It

grows from 5 feet to 6 feet high. In some gardens this height may not be desired, but where it can be grown it is much liked, as the haulm is covered with pods from the base to summit. It also keeps up a good succession of pods, these not coming in all at once, as in the case of many of the larger podded varieties.—G. WYTHES.

NOTES ON BROCCOLI.

Those gardeners who are expected to provide a daily supply of Cauliflower and Broccoli all the year round will have found the mild weather a great boon, as I think it will be acknowledged that it is one of the most difficult things in vegetable culture to have a full supply of Broccoli constantly all through the winter. Only those who are expected to do it are aware of the care and forethought required to prevent breaks in the supply, more especially when the garden is low and the soil heavy. Even on higher ground and with a light, sandy soil I find it no easy matter. One of the most important items is the selection of a limited number of proved varieties, planting out the strongest of each sort as soon as fit to handle, to be followed again a few weeks later by the weaker ones that will have grown and become stronger. My experience is that the last planted ones are often the most useful, as they come into use immediately after the first planted ones of the same sort, and continue the supply until another and later variety is ready. I have heard many complaints of spring Broccoli turning in now and causing anxiety as to what is to take their place in a month or two. If these had been planted at intervals as mentioned, I think they would not all be coming in now and forming a glut, to be followed by a scarcity later on. At the same time, it may be the varieties ordered were not true to name, and this explains the cause of their coming into use at an unseasonable period. The following are the sorts that I chiefly rely upon, and in both mild and severe winters they have proved their worth. For cutting, up to Christmas I have found none to equal Veitch's Self-protecting Autumn; when true to name it is all that its name implies. Following Autumn Giant Cauliflower it is one of the most useful varieties, and has never disappointed me. Snow's Winter White is a well-known and highly-esteemed sort, ready for use in mid-winter. The first planted batch of this is just over, and the next batch of the same variety is keeping up the supply in sufficient quantity to meet requirements. Backhouse's Winter White is a good successor to Snow's here, always ready when the latter is nearly finished; it is also one of the best to withstand wet and frost. Cooling's Matchless is an old variety, but one that I find extremely useful and reliable, and I should be sorry to discard it. Another advantage is its excellent flavour. Even when lifted and stored in sheds to protect from frost its flavour is superior to that of any others treated in a similar manner. April Queen is a variety that should be better known. It is very hardy, with lovely pure white heads ready in March and April; on a light soil it has proved first-class for some years. Veitch's Model will be ready by the time the last is over, and the value of this variety is proved by its greatly increased cultivation. Late Queen completes the list, and I have yet to see the winter that will seriously injure this variety, its season being May and June. Its keeps up a supply of large and tender heads until the Cauliflower is fit to cut. It is never advisable to be too conservative in selecting varieties, as novelties may, and do occasionally prove to be of extraordinary merit; but it is always safer to depend on well-tried

sorts that will not land the gardener in difficulties. We often see it advised that Broccoli should have the heads layered towards the north before frost sets in. Such a practice may be beneficial in some localities, but I must confess to not having discovered any advantage. Those plants not heeled over have passed through hard weather fully as well as those that were so treated. Of late years from the end of October onwards all Broccoli turning in has had the heads tied up, thus protecting them from wet and enabling them to pass safely through several degrees of frost: and if there has been any appearance of sharp weather, the plants have been taken up with a good ball of soil and placed in frost-proof structures.

W. G. C.

**Radish French Breakfast.**—As a good main crop and late Radish I doubt if there is a better variety than the French Breakfast. I have pulled roots daily from the open right up till the present time, but of course the mild weather has been the cause of this. If I had covered the roots with dry litter, I daresay I could have had them for a few weeks longer. A. Y.

**Flavour in Brussels Sprouts.**—I quite agree with the remarks of "E. J." on the bad flavour of some varieties of this useful vegetable this year. Several gigantic new varieties that were sent me for trial are so strongly flavoured on a light soil, that I have stopped sending them into the kitchen. The only really good and pleasantly flavoured sorts that I have are Matchless and Rosebery, the sprouts of both of medium size and very firm.—W. G. C.

**New Turnip Early White Milan.**—This is a valuable Turnip for sowing in frames or as a first early in the open ground. Last season it was very good and the earliest variety I have grown. In appearance it is much like Extra Early Milan and equally as early, if not earlier. Early White Milan is not large, and a distinct strap-leaved variety, coming into use ten days or a fortnight earlier than Snowball and other white varieties. The bulbs are pure white, not at all large, flesh sweet and of superior flavour. Its quick growth makes it a valuable addition to our list of none too many really good early kinds. For frame work the Milan type is unequalled, but for summer sowing in the open I do not advise it.—G. WYTHES.

**Salsafy.**—On the Continent, and especially in France, this vegetable is highly esteemed both by the rich and the working classes. It is delicious when properly prepared and so simple of culture, that one wonders why it should be so little grown in this country. In hard winters, when there is not too much variety in vegetables, Salsafy forms an agreeable change, and it is said to be one of the most nutritious vegetables cultivated in gardens. The seed should be sown early in April, but it is imperative that the ground be thoroughly prepared for its reception. It must be stirred a foot or more in depth. Ground that has been trenched a year or so previously will be just right and plenty of manure must be worked in. The seed drills will require to be about 1 foot apart and the plants thinned to some 8 inches from each other. Frequent surface stirrings will promote a free growth. On the approach of winter the roots should be stored in dry earth.—J. C. B.

**Selection of vegetables and new kinds.**—The seed catalogues now coming in fast remind us that the season of selection is close at hand. There will doubtless be the usual list of novelties and specialities which the older practitioner solemnly warns us to fight shy of. To the man who is interested in vegetables or flowers the growing of these novelties forms an agreeable change. I admit I have a failing for the new things. It may be said, Why spend money on novelties till one is sure of them? If the reports of trials or the awarding of certificates are noted, it will be seen how very few new fruits or vegetables, especially the latter, are awarded certificates, so that there need be little doubt as

to quality with such a rigid selection. We have more novelties now than in years gone by. Many appear as old friends with a new name, and I fear many are made improved selections merely to fasten a name upon them. In these days of cheap horticultural literature there is no need to solemnly abjure all new things, as was done in the old days when there was little chance of knowing the value of any new introduction. New things of any real value come to the front rapidly, so that one is soon able to know what to grow.—W.

#### WHAT'S IN A NAME?

FROM the letters that have lately appeared on the naming of plants, it is evident that there is a growing disposition to resent the crackjaw nomenclature that is now so much in vogue. The time is ripe for the return of that Peter Bell to whom a Primrose was "a common Primrose," and not "Primula vulgaris." Such an apostle would have many disciples, my humble self among the number.

We want, as "H. O. W." (p. 520) says, English substitutes for the erudite appellations that many of the lowly denizens of our gardens are now burdened with. Winter Flag is, I think, as good a name for *Schizostylis coccinea* as can be coined—better, certainly, than Flame Lily, as it is called by some, for neither is it a Lily nor is its flower of the hue of flame. Almond Cross for *Schizopetalon Walkeri* is undoubtedly well chosen.

Some of us are cursed (possibly there be those who will think I should have written blest) with a fatal facility for acquiring Latin polysyllables. If indulged in, this pernicious habit so blunts the moral feeling of those addicted to it, that there are men—and women, too, more's the pity—who will scarcely feel a pang of compunction when, after a pause (during which he or she has vainly endeavoured to assimilate a string of Latin words), one of those "good decent folk," alluded to by "H. O. W.," says with a sigh, "Dear me! what a very long name for such a little flower. Isn't there a simpler one?" Then, again, as "J. C. L." and "A. K." (pp. 550 and 13) point out, these Latin names are nothing if not inconstant. To-day *Hyacinthus*, to-morrow *Galtonia*; to-day *Tritoma*, to-morrow *Kniphofia*, in the correct pronunciation of which the "K" is, I understand, eliminated, the very name suggesting the wanton decapitation of the citizens of the parterre. *Aralia Sieboldi*, which we got to know so well, now masquerades as *Fatsia*. The *Belladonna Lily* has turned out to be the one and only *Amaryllis*, all the rest being now *Hippeastrums*, while the *Spiraea japonica* of our youth has been re-baptised *Hoteia*.

Then there are people who make matters worse by getting hold of a Latin name and mispronouncing it through what is really ignorance, though they consider it erudition. One often hears *Deutzia* called *Doitzia*, under the mistaken impression that it is a German word, and I once came across a linguist who, when talking of *Cactus Dahlias*, would persist in pronouncing Juarezi "Hooarezi," quite oblivious of the fact that although in the Spanish tongue Hooarezi is correct, the word directly it is Latinised is pronounced after the classic Latin fashion.

One can hardly leave the subject of nomenclature without deprecating the practice, yearly becoming more common, of christening novelties, especially in *Chrysanthemums*, with lengthy titles. The French raisers are the worst offenders in this respect, but Americans and our own countrymen are not blameless. *L'Enfant des deux Mondes* is a stumbling-block that

has brought many a good gardener to grief, and not only gardeners, but nurserymen as well, for I have at this moment two catalogues before me in which the name is mis-spelt. What excuse, too, can there be for Gaston Chandon de Brialles, Mons. Pynaert van Geert or Souvenir de Mme. Blandinières in *Chrysanthemums*, and Susanne Marie Rodocanachi or William Allen Richardson in *Roses*? All of these god-parents are doubtless very worthy people and quite undeserving of the odium which now attaches to their names through the misplaced obsequiousness of plant producers. S. W. F.

## GARDEN FLORA.

### PLATE 997.

#### THE GENUS LYCORIS.

(WITH A COLOURED PLATE OF *L. AUREA*.)

THERE are five species of *Lycoris*, and four of them are in cultivation in England. They are natives of Japan and China, and whilst botanically they are placed near to *Hippeastrum*, they more resemble in bulb, leaf, flower and habit some of the *Nerines*; indeed, two of the species, viz., *L. aurea* and *L. radiata*, are still called *Nerines* by nurserymen. All the species are sufficiently ornamental to rank with good garden bulbs, and they are probably easy enough to manage when their requirements are understood. Hitherto, however, we have not had much success with them, no doubt because the treatment they have had has not been suitable. At any rate, this is true of

*L. AUREA*, which has been in cultivation more than a century, having been introduced into English gardens by Dr. Fothergill in 1777, when it was called *Amaryllis aurea*. This is generally described as a greenhouse bulb, but I am now convinced that it requires warm house treatment. In July last we received from Hong Kong a box of bulbs of this plant. They were as large as the bulbs of Emperor Daffodil, and they nearly all looked promising for flower. Along with them came the following significant note—

I send you a box of *Lycoris aurea*, and I hope it will reach you all right. Is it not somewhat remarkable that these bulbs should remain dormant in the ground all summer in such a climate as this, with a temperature of 85° Fahr. in the shade and a rainfall of 100 inches in the year, heat and moisture sufficient, one would think, to start into feverish growth the most hide-bound of bulbs? The *Lycoris*, however, sleeps through it all, pushing up its tall scapes of yellow flowers at the end of our summer. Here it is one of the most popular of garden plants, ranking with *Crimmums*, *Pancreatium*, *Eucharis*, and *Lilium longiflorum*. I do not remember to have ever seen it in English gardens.

The bulbs sent flowered well at Kew, and they are now in full leaf in an intermediate house, a few of them having been placed in a hot stove as a test. The bulb is like that of a Daffodil; the leaves, which are numerous and start into growth along with the flower-scape, are like those of *Nerine sarniensis*, and the scape is 18 inches high, with an umbel of deep yellow flowers, like very large *Nerines*, strong bulbs producing twelve flowers in an umbel. Mr. Moon's drawing shows the beauty of the plant, and as bulbs of it are offered by Japanese nurserymen at a low price, it ought soon to become as popular as the Guernsey or the *Belladonna Lilies*.

*L. RADIATA*, often called *Nerine japonica*, is an old garden plant, for it was noticed by Kämpfer in 1712, and cultivated in England in 1750. It is a native of China and Japan, where it is commonly cultivated in gardens, and offered by the nursery-

\* DRAWN FOR THE GARDEN by H. G. MOON in the Royal Gardens, Kew. Lithographed and printed by Guillaume Severeys.

500-5000  
1000

men at about 2s. 6d. per hundred. It is very like a Nerine, Thunberg mistaking it for the Guernsey Lily, *N. sarniensis*, which it resembles in bulb and leaf, the scape being a foot long, with an umbel of from four to twelve red flowers, which are developed in early autumn. It generally flowers in October at Kew.

**L. SQUAMIGERA.**—In 1887 Herr Max Leichtlin and others distributed bulbs of this plant under the name of *Amaryllis Halli*. They flowered in several collections, notably that of Mr. Gumbleton in 1891, when he wrote that his plant had pushed up a flower-spike in July, which grew to a height of 2 feet, and resembled a strong-growing Nerine. It bore an umbel of five flowers each of about twice the size of the largest Nerine bloom and coloured lilac-pink, with a flush of blue down the centre of each petal. Mr. Gumbleton was disappointed with it. On the other hand, it has been described as a handsome plant, with a scape a yard high, an umbel of seven flowers, fragrant, 3 inches or 4 inches long, coloured light rose, shaded with a peculiar grey. It resembles the *Belladonna Lily* in bulb and leaf. It is said to be often planted by the Chinese in their cemeteries. According to *Garden and Forest*, it was introduced from Sanghai, China, by Dr. G. R. Hall, who cultivated it in China in 1860 and who sent it to Messrs. Hovey, of Boston, who distributed it a few years ago. It is said to be hardy, but the first bulb received at Kew perished in the winter, and since then it has been grown in an unheated frame.

**L. SANGUINEA.**—I saw a coloured drawing of this plant a short time since in the hands of a nurseryman, who said he had a consignment of bulbs of it on the way. It does not appear to have been cultivated in England, but from what I can gather it is likely to find favour with bulb growers. Its bulbs are about 1 inch in diameter, the leaves are linear, the scape  $1\frac{1}{2}$  feet long and the umbel six-flowered, the flowers being nearly erect and regular, over 2 inches long and coloured bright red. It is a native of Japan, where it is also cultivated in gardens.

**L. STRAMINEA** was introduced to Chiswick from China by Fortune in 1845, and was described by Dr. Lindley. I do not think it is in cultivation anywhere now. It is described as being very like *L. aurea*, but the flowers are pale straw-coloured, with pink streaks and red dots.

**L. SEWERZOWI**, a plant described and figured by Regel in his *Gartenflora*, t. 914, is now referred to *Ungermia trisphæra*, a large-bulbed plant with small red flowers. It is in cultivation at Kew, Dr. Aitchison having brought it from the Afghan boundary in 1886.—W. W.

—Owing to the difficulty that has been experienced in the past in flowering this very beautiful bulbous plant, the following note from a correspondent in China may be of interest:—

The temperature the *Lycoris* grows in varies from 93° in the height of summer, when the bulbs are resting, to 55°–60° in winter, when they are growing. Sometimes for a few days in January the thermometer falls to 40° or lower, but that is for but a short time. When the plants make their leaves there is absolutely no rainfall, or next to none. When they rest it is our wet season. It is a most lovely thing; I think it the most beautiful bulbous plant I have ever seen.

That the above treatment followed in this country will lead to success is, I think, most probable. At Kew last September a number of bulbs received when at rest from China flowered. These are now growing as freely as *Narcissi* in a temperature of 55°. I have also plants in a like temperature doing very well. When the foliage dies down I shall shut up the plants in a sunny frame and water sparingly. The beautiful *Lycoris squamigera* can, I fancy, be grown under the same conditions as *Amaryllis belladonna*; anyhow, it is quite hardy. *Lycoris sanguinea* is a comparatively unknown plant, I

believe, and a drawing I have shows a fine spike of very beautiful orange-red flowers.—R. W. WALLACE, *Colechester*.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**POT VINES.**—The canes started for early fruiting will now have made sufficient growth to be tied. In getting the rods into position it is necessary to use care to prevent the buds being rubbed off. If any Vine has not made sufficient progress it is better to allow the cane to remain in a bent position for a short time longer. The grower of these early forced plants must now determine which will be the fruiting growths. In some cases it will be necessary to remove some growths entirely. I am not an advocate for allowing a too great number of useless shoots, which rob the roots. With Vines now at the flowering period more warmth will be necessary and greater care in airing; indeed, very little air will be necessary. Up to this date little moisture at the roots will have been necessary where heating materials in the way of manures are used. If fresh heating material is required, it is better to place in position at once before the flowering period, so as to maintain a temperature of 80° at the roots. When adding new linings it is well to examine and test the roots as to dryness. In watering use tepid water. Much food will not be required till there is a liberal new root growth to absorb the food, which should be given in weak doses, the quantities being increased as soon as the fruit has set. With heated manure as the fermenting material the greatest care is necessary to prepare such before using, as when placed in heat the hot steam will greatly injure the tender growth in a close house. By using a liberal quantity of fresh leaves with the manure this is prevented, and a genial warmth is maintained for a longer time. Whilst the Vines are in bloom the evaporating pans should not be filled, and the glass of the house should be kept as clean as possible, as after fogs or near towns soot soon accumulates, causing a bad set and weakly foliage.

**VINES PLANTED OUT.**—Much the same treatment is necessary as with pot Vines. Those who force early and have a small well-built house will now have the growths on their Vines an inch long if ripe Grapes are required early next May. To get an even growth much better results are secured by covering the surface with warm manure as advised for the earlier pot Vines. Vines that have been forced for years may not require much to induce them to break freely, but young canes at this time of year often break irregularly if not assisted in this way. The night temperature for Vines at this stage should be 55°, with 5° to 10° higher by day, allowing the thermometer to run up freely by sun heat, disbudding as soon as possible to the required number of shoots when it can be ascertained which are required to fruit. During dull weather use the syringe sparingly, as the new growth just pushing will be injured if too wet. A safe plan is to get the canes dry by the time daylight ceases, there being sufficient moisture in the house after that time without syringing. With only a limited amount of daylight and little sun it is not wise to apply moisture too freely.

**MIDSEASON GRAPES.**—To have well-finished Grapes in quantity in July it is well to start the Vines at this date. The borders should ere this have been top-dressed, examined as to dryness, and the rods cleaned and prepared for forcing. Disbudding and syringing will be the principal work for a time. Old Vines show a great number of buds. These need thinning out as soon as the strongest can be selected. Where practicable a bed of leaves is of great assistance to the Vines, as it saves the syringing and a nice moist atmosphere is maintained. For houses just started the temperature may range from 45 to 50 by

night and 10° higher by day, but with young Vines in mild weather a few degrees higher may be necessary. Should the roots be outside, a good depth of warm leaves and litter will be beneficial, covering over the heating material to throw off heavy rains and snow.

**LATE VINERIES.**—All fruit should now be cleared from the Vines and bottled. It should be placed in a cool room, as if a suitable temperature is maintained and some small pieces of charcoal placed in the water, the bunches keep quite as well, indeed better than on the Vines. Pruning should be done as early as possible to give the Vines a rest. Cleansing the rods and all portions of the house should follow, removing all loose bark, but not scraping, as is at times practised. Any loose bark may be removed, the rods washed afterwards with warm soapy water and thoroughly scrubbed should mealy bug or other insect pests be troublesome. I attach more importance to thorough washing than painting, as the washing removes the insects, and if a strong solution of soft soap is used few escape. Painting over afterwards is necessary, a good mixture for this purpose being Gishurst compound, sulphur and clay, with a handful of fresh lime, making the mixture like thick paint, and taking care to freely cover the rough or knotty portion of the stem and crevices. The walls should be limewashed with fresh lime, and if mildew was present last season, use sulphur freely in the wash. Remove the loose surface soil and top-dress with good loam and some approved fertiliser. Previous to the surface dressing a thorough soaking of water should be given, as the roots will have got dry during the time the Grapes were hanging. Any additions to borders or renewal of same should be done.

**MELONS.**—Now is a good time to make a start with these, and if an early lot of plants was raised in December they will be in condition to plant out at this date. For very early fruit pot culture is best, as the roots being confined the plants make a short-jointed growth and soon mature fruit. For pot plants a certain amount of bottom heat is necessary. The pots may be plunged in manure, or, what is better, stood over hot-water pipes. Fourteen-inch or 16-inch pots will finish three or four nice sized fruits. The soil should be of a firm loamy nature, with such additions as burnt wood ashes, mortar rubble and bone-meal. If manure is the means of bottom heat it is well to place the pots on a firm base, as if on the manure there is a shrinkage, and when the plants are tied to the trellis they suffer in consequence. Much care is necessary at this early date. At the start, water must be sparingly given, and what little is required should be given in a warm state. A night temperature of 65° to 70° should be maintained, with a liberal rise during the day. The glass at night may with advantage be covered in severe weather. Another sowing should now be made, and in many gardens this will be the first. I prefer to sow in small pots, sowing a couple of seeds in each, thinning to the strongest when above the soil. No moisture will be required if the soil is damp till the seeds have germinated.

**STRAWBERRY FORCING.**—Now is a good time to introduce plants into heat for April fruiting. I rely upon *Vieomtesse H. de Thury* for first use, and those who have this variety and have not started forcing may now begin with every chance of success. If a slight start in the way of bottom-heat can be afforded the plants, so much the better. I use frames for this purpose, with a good depth of fresh leaves. Before introducing the plants into their forcing quarters it is well to make sure they are free of mildew. If not, a thorough dressing of sulphur should be given, dusting all parts of the plants, specially the under side of the foliage. Plants started early in December will now be showing their flower trusses, and as soon as they have pushed well above the foliage the plants may be removed to warmer shelves, as less moisture will be required. Care must, however, be taken not to give a check in any way, as doing this will cause abortive blooms. When removing from one house to another choose a warm day and do the work quickly. A higher temperature may

be given when the fruit has set. For succession crops such varieties as Royal Sovereign, La Grosse Sucrée, President, Auguste Nicaise, and the good old Keens' Seedling, where it is grown from a true stock, are valuable. The first named is a valuable addition to our early fruits and as early as Noble, with superior flavour. Shelves in fruit houses can often be utilised from this date. I do not recommend removal of surface soil or top-dressing when placing indoors, as this destroys the small roots. By the time the roots lay hold of the new soil the crop is cleared, so that the surface dressing is wasted. It is very easy to feed later on. G. WYTHES.

#### KITCHEN GARDEN.

**MAKING HOTBEDS.**—In the majority of gardens the middle of January is the best time for making up hotbeds for early vegetables. In the first place the frames should be measured and the site marked out, driving in a stout stake at each corner as a guide to the workmen, and allowing sufficient room for a 2½-foot or, better still, a 3-foot lining. Rank stable manure is best avoided, as it causes the bed to heat excessively for a short time and then to go cold. If sufficient leaves cannot be had, vegetable refuse or old garbage, usually found on the premises at this period, may be added. Let the bed be well trodden at intervals, using short litter for the outsides to bind it and finishing off with a good slope towards the sun. The frames should at once be placed in position and the soil thrown in. If soil is scarce, that used last year may again be used, adding a little leaf mould to keep it open and a sprinkling of some approved fertiliser.

**POTATOES.**—If an early variety, such as Ring-leader or Victor, had been placed in an intermediate heat a few weeks ago, sprouts a quarter of an inch long should now be formed. These should be reduced to a couple on each, these being left at the extremity of the tuber. They may be planted in rows 15 inches apart and 1 foot between the tubers, and about 4 inches deep. If no steam is engendered the lights may be kept closed until growth appears, when a little air must be given in mild and sunny weather.

**CARROTS.**—If these are sown in very shallow drills 8 inches apart, plenty of room will be left for intermediate rows of Radishes. These will be drawn before the Carrots are large enough to be shaded by them. A row of Ellam's Early Cabbage or the pickling variety, where autumn sowings failed, may also be sown. Carrots at this date liking plenty of heat, this may be increased and growth accelerated by keeping the frame well matted down by day as well as night till growth appears. A strict watch, however, must be kept, as if darkened after once through the soil the Carrots become drawn and blanched. A row or two of the old French Forcing may be sown, this being perhaps the quickest bulbing variety, also Nantes Horn and Market Favourite, the latter being about the best frame Carrot in existence.

**RADISHES.**—If a frame can be devoted to these, so much the better, as sown between rows of Potatoes they seldom do much good. Broadcast fashion is the best mode of sowing, raking the seed in a quarter of an inch deep and making the surface firm. Air must be regularly supplied when frost is absent, or the Radishes soon become leggy and useless. For quick growth the old variety Wood's Frame is still hard to beat, French Break, fast being also an excellent variety.

**SPROUTING POTATOES.**—Successional supplies of tubers should now be placed in boxes containing a little leaf-mould and removed to comfortable quarters to sprout; these will do duty in frames and pits without heat in February and also for the earliest borders in March. Ring-leader, Veitch's Ashleaf, Puritan, and Sutton's Seedling are all good for this purpose, the tops of the latter two being pinched when a foot high if grown in frames.

**FRENCH BEANS.**—January-sown batches of Osborn's Forcing and Syon House will make rapid progress, shallow boxes, where these can be accommodated, being the best receptacles. The

soil in these being only of moderate depth and not liable to become sour, a little artificial manure may be added, as the roots from the start will be able to assimilate it. Avoid earthing up, as it often causes wholesale rotting of the stems. Advancing crops must be supported by sprigs of Hazel or Birch.

**PROTECTING TENDER CROPS.**—Should sharp frost continue, dry Bracken or stable litter should be freely distributed along the tops of the Celery ridges, also between breaks of tender Broccoli, a portion of the same being laid on the tops of the latter and removed when a thaw occurs. Scotch and other Kales growing in isolated places must be inspected, as wood pigeons frequently do much damage before their presence is detected.

**JERUSALEM ARTHOCHOKES.**—Presuming that a sufficiency of these has been housed for present use, the remainder may all be lifted as soon as the frost goes and sorted. The smaller offsets may be covered with straw and ashes ready for planting in March, and the eating tubers stored away in soil in the root shed.

**AUTUMN-SOWN PEAS.**—In some gardens November sowing is still practised, and the growth will now need protection from cold frosty winds. Spruce or common Yew boughs form effectual screens if placed up each side of the rows. I have for years used troughs made of 12-inch deal boards, nailed together so as to form a span; these are placed quite over the rows in severe weather. A coat of tar every third season will prevent rot and preserve them for many years. Where early Peas were not sown in pots and placed in cold frames in December, they must now be sown; now, however, the pots must be placed in an early Peach house or similar structure, and there kept till growth is an inch high, after which they must be removed to a cold frame to harden off. Chelsea Gem and William Hurst as dwarf varieties, and Exonian and William the First in the taller section, are all good for early border work. A little seed of Stratagem may likewise be sown, as it is hardy and follows very closely on the heels of the first earlies, and there is no better Pea for quality or to fill the basket. Mice usually find out early sowings, whether in frames or in the open. The old-fashioned figure 4 brick or tile trap takes them sooner than anything else.

**DESTROYING WIREWORM.** In all gardens where wireworm is troublesome amongst Spinach or other crops, the present is a capital time to give a good dressing of gas-lime, the same being afterwards dug in. This will banish the pest, and allow sufficient time for its injurious properties to pass away before the spring crops are sown. While speaking of insecticides, I would add that the present time is favourable for burning up all sticks, fruit tree prunings and sundry garden rubbish, this affording a good supply of ashes for sowing in the drills of Onion and Carrot beds, for incorporating with heavy and unfavourable soils generally, and for sprinkling over Turnip and other crops when attacked by fly.

**ROOT ROOM.**—Inclement weather will afford an opportunity of overhauling the occupants of the root-shed. Carrots, being particularly liable to rot, must be first looked to, any that are partly decayed being laid aside for present use. Salsafy and Scorzoneria, if growing, should have the tops removed, or they will quickly rob the roots of vitality and cause shrivelling. The same may be said of Beet, but in removing the growth care must be taken not to injure the crown so as to cause bleeding. All seed Potatoes stored in cellars or outhouses must also be looked over and all sprouts removed; if lying thickly they should be spread out so as to avoid heating.

**HERBS.**—Roots of Mint and Tarragon should now be placed in boxes of soil or, failing these, large pots, as there is always a call for these in early spring. Some seed of Chervil may also be sown, so as to be on the safe side should it be asked for.

J. CRAWFORD.

**American Oaks.**—We have received the following from Mr. Meehan (once of the *Gardeners'*

*Monthly*) as regards seedling *PERNIX* grafted Oaks "The article you refer to was written by my brother Joseph, who has charge of one of the leading departments in our nursery, and has received very wide attention. There is something peculiar about grafted Oaks. Some of them do very well grafted; for instance, the upright variety of the English Oak will unite and thrive just as well on the ordinary English Oak stock as if it were raised from seed, but the blood-leaved Oak and several other varieties utterly refuse to live more than a year or two without becoming sickly. Undoubtedly it is best in all cases to raise them from seed. In this country, where it is so easy to get seeds of all kinds of Oak, there is, of course, no necessity for grafting, so that those we offer are seedling plants. Here in Pennsylvania, where we are between the most tropical and the more arctic parts of the continent, we never suffer much from heat or drought in summer or severe cold in winter; in fact, the climate of Pennsylvania more nearly resembles that of England than that of any other portion of the United States. It is only, as a general rule, from the middle of December until the middle of February that we are unable to do outdoor garden work, and very often we continue our tree planting until after Christmas."

#### BOOKS.

##### THE BOOK OF THE ROSE.\*

THE comprehensive title of this book is an illusion which its author very quickly dispels. A book of the Rose should surely treat of all the charming attributes of the flower, but Mr. Foster-Melliar looks upon the plant "only as a means of obtaining glorious Roses." As a decorative plant he does "not consider it pre-eminent," and to his mind "simpler, less beautiful flowers have greater value for general effect in the garden." From his own point of view, that of an exhibitor, he is able to teach, but, except in a few minor details of treatment, he has nothing new to tell us. There is plenty yet to tell about Roses, and though treatment from an exhibitor's standpoint has been dealt with, there is still room for a book about Roses which can be offered without apology, provided it appeals to and supplies the wants of the thousands of lovers of the queen of flowers who give it pride of place in their gardens and never trouble themselves about exhibiting. The Rose is unfortunate in its literature, because it is all one-sided and conveys the impression that the end of all Rose growing is the production of exhibition blooms. No one grudges the enthusiast his right to treat the flower as he likes, but the standard of requirements for show is so exclusive, that he who grows for this purpose alone has not a true idea of the varied beauty of the flower. So long as exhibitors of Roses alone teach Rose growing, their modes will be "erroneous and faulty," being altogether opposed to the development of the flower except as an individual bloom. Everything is restricted, and the few shoots and flowers, however fine in themselves, are but a miserable apology for the self-same Rose as grown as seen in the garden. To deify the flower on the ground of effect is absurd, as the commoner showy flowers only gave bright effects because they were massed in quantity, and if we take the best Tea, Monthly and other Roses and mass them accordingly, there is no other flower that will give more beauty in its season. Mr. Foster-Melliar is not without a good example in his vicinity, and if he had stood as I did one day last June on the terrace at Shrubland and looked upon those noble groups of Tea Roses that have replaced the wretched carpet bedding, I cannot but think in his introductory chapter he would have freely admitted that the Rose as a garden flower has great merits, and in its amazing profusion of bloom makes a picture.

\* "The Book of the Rose." By the Rev. A. Foster-Melliar. Macmillan and Co.

The second chapter deals with history and classification, and the author is guided by those who have gone before him, although there is much that is useless and confusing, owing to the retention of such groups as Boursault, which have no garden value. The statement (p. 21) that several other single species which bloom only once a year are only of value to the botanist or collector is quite in accordance with the erroneous ideas that the exhibitor puts forth, and a hindrance to the full realisation in our gardens of the varied types of Rose beauty. Thus the single Musk Rose, the sweetest and handsomest of climbing single Roses, is banished from gardens and beneath notice. 'Amongst Monthlies, Mrs. Bosanquet and Mme. Laurette Messimy are mentioned as about the only two worth growing, and this latter is condemned as a weak grower, when it is not. There is a bed of Monthly Roses and Lavender on the terrace at Shrubland that is gay for many months and brilliant at certain times. The bed does not contain either of the two kinds above mentioned, but those that are there are beyond question equal in beauty and effect to the best Teas, though less useful as cut flowers. Rosa lucida, a gem among single Roses, is classed on p. 26 along with R. microphylla and berberifolia as "not hardy, but evergreen where well protected," R. lucida being as hardy as the wild Bramble. The last paragraph of chapter 2 relating to garden Roses is not of much use, for it sums them up as "hardy, strong-growing, free-flowering sorts which do not require much care, but are defective as florists' flowers." This is curious considering that some of the very best Tea Roses for the garden are those that the exhibitor finds indispensable.

Situation and soil are fully treated of in chapter 3, but the ghost of tenderness once more stalks abroad, for "It is pretty well known that most of the Tea Roses are tender and likely to be injured or killed by severe frosts." After describing the various situations, and mentioning as worst of all one that lies low, near trees and water, and hardly above sea level, the author admits that it is in just such a situation he has to grow his Roses. In this valley of the Gipping the thermometer often falls to zero. The experience gained in such a place is surely not for general guidance, and the disasters that have followed are not lying in store for us all, as Mr. Foster-Melliar would have us believe. He calls Tea Roses "tender, delicate things." If they are, it is marvellous that the great growers around Colchester have any flowers to exhibit when the shows come round, and plants to sell later on. Yet there they are in countless thousands, in open fields exposed to all the winds that blow. Planting, manures and pruning are the subjects of the three next chapters, and are well and fully treated. Next comes one on stocks, and it is satisfactory to note that the Manetti is estimated at about its true worth. The Brier cutting is regarded with most favour, having less tendency to deep rooting; but as the seedling Brier stocks are once or twice transplanted before working when long roots are shortened and planting the plants after the directions given in the book, the differences must be more fancied than real. Propagation is the subject of chapter 8, and deals chiefly with the conventional methods, but we are told how to strike them, although this advice is preceded by the oft-repeated assertion that in the first place it takes longer to form plants, and, secondly, such Roses neither grow nor flower so well as those on stocks. With a few exceptions, they will grow and flower just as well on their own roots if we adapt our culture to the needs of the plant, one of the first of these being the need of a much lighter soil. As to the time occupied, if anyone will put in some Brier cuttings and Rose cuttings at the same time, he will certainly be cutting Roses from the own-root plants before there are any upon the plants that have been budded. This is a fair test of time, but not so when a cutting is compared with a bud put upon a crown of strong established roots. Easier and more rapid still is layering.

Shoots put down in early summer may be taken off in late autumn with quite an abundance of roots, the H.P.'s especially being of easy increase in this way.

Pests are well treated of and the best remedies suggested, whilst a short chapter follows on Roses under glass. Exhibiting has a special chapter, as the author thinks anyone who has followed his instructions previously given will be anxious to get an important judgment on his blooms. He exaggerates the views of those who are rather averse to Rose shows, for no one who knows anything at all about the flower would say that the "least lovely of Roses are most shown and encouraged." I fear the exhibitor takes a much narrower view of the whole matter by reason of his "high standard of excellence," for there are lovely Roses grown in gardens to-day that would never have been there if the shows and the showing people had been our sole guides and counsellors. The "manners and customs" of Roses form the subject of a very long chapter extending to nearly one hundred pages and illustrated with flowers of some of the best kinds, specimen flowers showing the form admirably, whilst the text treats of the merits and peculiarities of growth and flowering. A chapter follows on selections for various purposes, and though no two compilers might be expected to agree on this, it is surprising to find Bouquet d'Or placed sixth in the order of merit in a selection of twelve Roses for a wall, and precedence given to Maréchal Niel (ever uncertain) and Reine Marie Henriette. For perging down some advised are useless, as La France and Gloire de Margottin, whilst one of the very best, namely, Mme. G. Luizet, is not mentioned. The final chapter contains a calendar of operations for each month in the year. It is a useful book to put into the hands of a beginner, and will be an all-sufficient guide if his ultimate aim is prize-winning. The style and arrangement are admirable and the printing good, but the illustrations are processes of a poor sort. A. H.

FLORA ODORATA: OR, SWEET-SCENTED FLOWERS AND FRAGRANT LEAVES.\*

THE object which this little volume so well fulfils is to give concisely, and in the most convenient form for reference, what was greatly needed, namely, all necessary practical information about the sweet-smelling flowers, shrubs and plants which are found in our gardens, fields and hedges, not excluding those which come to us from other countries and climes from America, the East, Australasia, and are not hardy in these islands, like the Olearia, Eucalyptus and many others. In the "historical sketch" which precedes the main alphabetical list of sweet-smelling plants—which is the main purpose of the book—there is a great deal of interesting matter concerning the use of sweet-smelling flowers and herbs in the distillation and manufacture of perfumes from the earliest recorded times, and also the association of aromatic plants with the religious and social observances of the most ancient peoples. Thus in the East "scented flowers and the shade of perfumed trees were considered one of the most indispensable enjoyments of the higher classes of society," as they are now in fact; and again, "the luxurious and refined habits of the Assyrians involved the use of perfumed plants to an excess," and we read of one potentate who, driven to extremities by continuous defeat, "caused a pile of fragrant herbs to be lighted, and, placing himself with his wives and treasures upon it, all were swiftly suffocated with aromatic smoke." The Egyptians also made the most luxurious use of fragrant incenses, and the Greeks "ascribed a divine origin to perfumes." Sweet-smelling flowers—the Rose particularly—play a prominent part in Eastern fable. Later and in our own country the poets are seldom

\* "Flora Odorata: or, Sweet-scented Flowers and Fragrant Leaves." By Donald McDonald. With an Introduction by W. Robinson. Sampson Low, Marston and Co., Limited.

happier than when telling of the beauty of our native flowers. It is, perhaps, not generally known that the once much used, but now rather out-of-date, scented Patchouli comes from an Indian herb of that name, and from a tree found on the islands of the Indian Archipelago comes the perfume known as Ylang-Ylang, which name signifies "The Flower of Flowers." The attar of Ylang-Ylang is more costly than even the attar of Roses, and the odour of the tree is so powerful that it scents the air for miles around. The chapter on the sweet Violet is very interesting. American Violets, it seems, are scentless, though the flower "in all its fragrance blooms beneath the Palm trees in many lands. The sweet Violets of Palestine blossom with the Narcissus and the Hyacinth in the opening month of the year, and at that time, too, the women of Aleppo gather them to adorn their dark tresses." The book is well printed, and I heartily commend it to all interested in the subject. C. F.

A DICTIONARY OF HORTICULTURAL TERMS.\*

THE want of a good polyglot dictionary of horticultural terms is often felt by English readers of foreign horticultural journals when they meet with technical gardening terms the explanation of which is not to be found in any ordinary dictionary; and, similarly, foreign readers of our English horticultural papers must frequently be equally at a loss in this respect. Under these circumstances, we hailed the announcement and subsequent receipt of the present volume as of something to be thankful for.

The gratitude, however, which we had thus prospectively entertained was turned into disappointment when, having gone carefully through the book, we found that it is not of the slightest use to anyone who may want to ascertain the French, German, or Dutch equivalents for even such common horticultural terms as layering, mulching, standard, espalier, bell-glass, and many others, not one of which is mentioned in its pages. In fact, notwithstanding its title, the book is singularly deficient in horticultural terms, as in its eighty-three pages we have failed to discover more than thirteen of such terms, viz., cutting, fork, frame, fruit-garden, grafting, grafted, grafter, graft, greenhouse, hotbed, mattock, nursery, trellis. Instead of supplying useful information of this kind, the author gives us in the first of the five columns into which each page is divided an alphabetical list of such Latin and Latinised-Greek words (mostly adjectives) as occur in purely botanical descriptions of plants, and of which the bare and general meanings, as given by him, can be just as readily found in an ordinary Latin dictionary. Hence we fail to see the *raison d'être* of the present volume, and are utterly at a loss to know why it also contains such words as nitrum, saltpetre; statutum, statute; and vaccinatio, vaccination.

The task of compiling a good polyglot dictionary of horticultural terms is still open to anyone who has the courage to attempt it and the facilities for carrying it out. Books on the subject, if he can get them, will be only a partial aid to him, but a visit to some of the great continental horticultural establishments, with a complete list of our English horticultural terms and note-book in hand, would enable him to furnish himself with equally complete and correct lists of equivalent foreign horticultural terms.

The plan of such a dictionary, to be really useful, should be different from that of the present volume, which only gives an alphabetical vocabulary of the Latin words in the first column, followed by their meanings in English, French, &c., across the page. A proper polyglot dictionary of horticultural terms should be divided into as

\* "Dictionnaire Latin-(Grec)-Français-Anglais-Allemand-Hollandais des principaux termes employés en Botanique et en Horticulture." Par A. M. C. Jongkindt-Connex, horticulteur à Bussum, près d'Amsterdam. Haarlem. 1894.

many sections as there are languages represented in it, the terms of each language being arranged in alphabetical order in the first column of the pages devoted to the section of that language. It would then be easy for a Frenchman, say, to find in the alphabetical arrangement in the first column of his section any French term of which he wanted to know the equivalent in any of the other languages and which he would then find in a line with his own term in its proper column on the same page; and similarly in the case of an Englishman, German, &c.

Awaiting the advent of such a polyglot dictionary of horticultural terms as we have here endeavoured to give an outline of, we cannot conclude the present remarks without expressing our regret that the volume before us, the title of which had led us to expect much, should, upon examination, have turned out to be so lamentably deficient in technical horticultural terms and so unsatisfactory in its plan of arrangement. W. M.

## FLOWER GARDEN.

### AMARYLLIS BELLADONNA.

THERE are few more taking sights than a border with several hundred scapes of this lovely *Amaryllis* in bloom under an autumnal sun. Such an one, extending the length of a range of glasshouses and containing over a thousand bulbs, I saw in 1893. I was told that never before had the flowers been so abundant, and quite believed the statement, as the flower-heads formed a 2 feet high cushion of pink and white, unbroken throughout the length of the long narrow border. Whatever may have been the case in other parts of the kingdom—and from Mr. J. Wood's note (January 13, 1894) it would seem that in some districts the season of 1893 was not productive of much bloom—I believe that in the south-western counties, at any rate, bloom was exceptionally profuse, while in four cases that came under my notice the crop of flowers was admittedly a best on record. Last season the four borders in question produced but a scanty show.

There is more than one variety of the *Belladonna Lily*, that figured in the accompanying cut being an exceedingly beautiful form. Seven years ago I brought home from the Cape of Good Hope one bulb which has now increased to six. The individual blooms are very gracefully shaped, the petals recurving far more than

The *Belladonna Lily*. Engraved for THE GARDEN from a photograph sent by Mr. S. W. Fitzherbert, Torquay.

in the ordinary variety, and their colour, instead of white, with a well-defined dark pink edging, being of a uniform flesh colour. The individual flowers are also larger and borne in greater numbers on the scape, one scape this autumn carrying fourteen blooms, and two others thirteen each; the scent is also of a rarer fragrance.

The bulbs in question have always been in pots, being kept in a moderately warm house

whilst making their growth, transferred to a cold frame when the foliage has died down, and, finally, put into a cold greenhouse as soon as the flower-spike showed. When in flower these, or plants of the common form, are excellent for rooms, lasting in beauty from two to three weeks.

In its natural habitat this *Amaryllis* blooms from January till March, at which time *Vallota purpurea*, which is found in quantity in the same region, is also in bloom. On being imported it will often be found that the first flowering will take place in the spring, but gradually, owing to the insistence of a changed climate, the blooming period will be later until it becomes autumnal.

A soil composed of loam, leaf-mould and sand in equal quantities will be found most suitable, nutriment being supplied during the period of growth in a liquid form.—S. W. F., Torquay.

— Why so handsome a plant should be so seldom seen it is very difficult to say, the more so as we see species and varieties of plants far less ornamental and much more difficult to manage, taking up valuable space and time. When once planted in the proper position there is only one thing necessary to ensure success, and that is to let the bulbs alone. Some amount of patience is, however, necessary while the bulbs are becoming established, this taking from three to five years, and depending to a considerable extent on the size of the bulbs when planted. Once they are established they should not be disturbed for years, when they will each year be a source of pleasure and increased beauty in any garden. The position the bulbs should occupy is of considerable importance, and there is no better place than at the foot of a wall with a south aspect. In such a place they will be dry, warm, and well drained, which are the more important details to success. A good depth of soil also is of primary importance. The soil should if fairly good be dug to a depth of 3 feet, or, failing a sufficient depth of soil, it will be best excavated to this depth and replaced by suitable material. Rough, lumpy peat and good fibrous loam of a somewhat stiff character, in equal parts, may form the bulk. To two barrowfuls of the above add one bushel each of partly decayed leaves and old mortar rubbish. Six inches or thereabouts of brickbats to form a drain should be placed in first, laying some rough soils of turf cut thick over the drainage, then fill in the soil to about 18 inches of the surface. At this point turn in some partly decayed cow manure, adding 3 inches more soil and mixing the whole together in the trench. Now add another 3 inches of soil without manure, and having made the soil firm, plant the bulbs

—that is to say, the base of the bulbs should be from 10 inches to 12 inches below the surface, the bulbs themselves being of large size. Place a layer of sand at the base of each bulb and also surround the bulbs with the same material. In covering the bulbs make the soil quite firm. The best time in the year to replant this *Amaryllis* is the month of June, though bulbs in the dry state may be obtained at the present time from the best dealers. These should be planted at once. Some may think possibly that this plant requires a good deal of trouble, but no one who has seen the grand masses of it flowering beside one of the *Orchid* houses at Kew could ever regard any trouble too great to secure similar results. Here may be seen bulbs producing two, three and sometimes four spikes each, the latter rising to nearly or quite 2½ feet high, bearing as many as seven or nine flowers in an umbel.

Some of the rose-pink shaded flowers are extremely delicate, while others are equally showy in their purple-red tints, and others, again, are white, washed or suffused with satin-pink. Where healthy and good bulbs are planted at the start, these will become established in a year or two and give no more trouble beyond watering them in their growing season and occasionally with liquid manure.—E. J.

### ENOOTHERA MARGINATA.

THE illustration represents this charming variety of the Evening Primrose as growing on a sunny bank in Messrs. Veitch's nursery at Exeter. In spite of the past somewhat unfavourable summer the plant flowered most abundantly throughout the whole season, producing a fresh flower or two nearly every day. The individual flowers, fully 4 inches to 5 inches in diameter, are of the purest white, with just a faint touch of pink on the under side of the petals. The plant is rather

*Enothera marginata*. Engraved for THE GARDEN from a photograph sent by Mr. F. W. Meyer, Exeter.

susceptible to too much moisture on the foliage, and therefore succeeds best when planted on sloping ground. At Exeter, Torquay, Newton Abbot and other places *Enothera marginata* is growing in rather heavy loam, in which it seems to thrive remarkably well. It is a valuable plant for a sloping border or for the rock garden. It does not grow more than 8 inches or 9 inches in height, but spreads out sideways rather rapidly when once established, and should therefore not be associated with the smallest alpinists.—M.

— On the rockery at Carleon, Killiney, Co. Dublin, there is quite a remarkable colony of this fine plant. It was originally planted on a bed raised about 2 feet above the common level by supporting stones, and, probably pretty well planted at first, it has extended to the right and left, has gone backwards, come over the stones and crept down to the walk below, covering a space of about 8 feet square each way. In the genial climate of this neighbourhood it flowers in the freest possible manner all through the season, and is quite one of the most admired plants in this well-stocked garden. Another probably unique rockwork plant to be seen here is *Rhynchospermum jasmoides*, pegged down and covering quite a large space, much cleaner and more healthy than one generally sees in greenhouses.—T. SMITH, Newry.

**Lobelia fulgens.** — My plan is to take up the plants about the beginning of October and to put six or eight together in a seed-pan, some soil being left attached to the roots. They are put into a somewhat sheltered cool place and left there for three weeks; after this they are housed, and two weeks later the stems are cut or broken off close to the soil. The house is kept just above freezing

and moisture moderately given. Thus they remain until the middle of January, when they are divided, brought to the warmer house, and plunged in a border of coal ashes which is slightly warmed by a flue from underneath. In three weeks they are established, when they are hardened off and brought to the greenhouse. In this way I do not lose any by rot.—MAX LEICHTLIN, *Baden-Baden*.

**Corydalis cava var. albiflora.**—This is a very pleasing white form of the hollow-rooted Fumitory, and coming very early into bloom is very useful in spring gardens. It was a great favourite with the late Mr. William Ingram at Belvoir. It forms an excellent companion to the species which produces purple blossoms from February to May. Provided the soil be not too dry the *Corydalis* will flourish under trees. The yellow *Corydalis* (*C. lutea*) is a well-known plant, but it is later in blooming than *C. cava* and its white variety.—R. D.

#### WILD PRIMROSES.

THE early winter of 1894 has been exceedingly mild and pleasant. One marked peculiarity has been the abundance of wild Primroses. For some reason, which I can never quite understand, Primroses and Polyanthuses are generally fairly plentiful in our gardens through November and December—that is, if the weather is at all favourable to their development. But wild Primroses in the hedgerows and woodlands are usually not to be found till the warm sunshine of the end of February or March has brought them out timidly to greet us in our walks. I remember once when quite a lad out shooting on the cliffs near Fowey, in Cornwall, on New Year's Day, I came across a bank which was yellow with a mass of early Primroses; but that was in the far west in a sheltered nook, and I have never met with anything like it again till this year. This year the same thing has actually occurred in Gloucestershire. In a certain wood, protected from the north and east, Primroses have been flowering profusely all through November and December, so that not merely a few isolated blooms could be picked, but baskets have been filled with the delicious fragrant flowers. This is certainly a very strange phenomenon, quite unprecedented in the memory of anyone living in the neighbourhood, and therefore not to be explained merely by the fact of a mild winter, because we have had many mild winters, but no wild Primroses. I think possibly the explanation is to be found in the great drought of 1893. This is an exceedingly good country for Primroses usually, but last spring they were very scarce, so much so, as to strike one in walking through the country lanes, and still more in the woods and orchards, some of which are usually carpeted with a mass of Primroses. It seems to me that the great check thus experienced prepared the plants for an earlier bloom in the following season than is their wont; and when a mild November and December promoted growth, the pent-up vigour burst out into the extraordinary display of bloom we have lately had. If so, it might enable us to control the flowering of other things by keeping them without water. But drought was not the only peculiarity of 1893; the great heat has also to be taken into account. I lost quantities of Primrose plants in the beds in my garden. They withered with the heat and drought, recovered slightly after a summer shower, but only to fall off into a worse condition when the dry weather settled in again.

I must tell you that the cottagers who live in the wood from whence this strange crop of Primroses has been gathered have a different

theory to account for it. They say that the plants were trampled down by horses drawing wood last spring, and that promoted their growth at an unusual time. I do not think that this would account for it. I do not suppose that any of your readers have ever seen baskets of fine, healthy Primroses, such as we generally find at the end of March and beginning of April, gathered in the woods at Christmas. I have never heard of such a thing before, and I think it is worth while recording the fact.

I wonder what they would have thought of them at Covent Garden done up in sweet little button-holes, with tiny fronds of wild Fern just tinged with russet, but fresh and green otherwise, and nestling in a surrounding of beautiful Moss. I have plenty of *Odontoglossum Rossi majus* in flower at the present time in the greenhouse, but I would rather have a button-hole of these unexpected Primroses than even one made of that beautiful Orchid. There is nothing like the fresh scent of the wild flower from the woods, unless possibly it may be the peculiar and delicious fragrance from the curious little flowers which grow on the bare stems of *Chimonanthus fragrans* at this time of the year. I have a saucer full of these precious flowers by my side as I sit by the Christmas fire, and every draught caused by the slightest motion in the room wafts that wonderful scent across one's face. Yet how few people know of its existence.

#### A GLOUCESTERSHIRE PARSON.

#### THE QUILLED GERMAN ASTER.

I THINK the quilled German Aster is beginning to be more generally recognised as a valuable type for cutting than it was a few years ago. Of late years there has been a tendency to grow larger Asters, of which the Comet is the latest type, and a kind of reaction against these grosser forms is setting in. For beauty, symmetry, chasteness and variety, the quilled Aster—provided, of course, the strain is good (and there is a difficulty in obtaining one at the present day)—is unequalled, if we except the bouquet varieties among the flat petalled types. It may be objected to that the growth of the quilled Aster is rather tall and the flower-stems spreading, yet a line of plants of uniform height and quality is a very pleasing object in a garden. The stems are long, stout and rigid, and therefore particularly well adapted for cutting, and they endure fresh and bright for some time in a cut state.

As an exhibition flower the quilled Aster is very attractive. In the west of England one sees them at their best. The shows held at Taunton, Bath, Trowbridge and other western towns bring together superb stands of this flower, produced by means of good cultivation. The quilled Aster bunches well, as has been demonstrated at some of the meetings of the Royal Horticultural Society—much better indeed than some of the large flat-petalled types.

Those who grow for exhibition sow the seeds thinly in the month of April, using pans of very rich soil, with a mixture of leaf mould and a liberal allowance of sand. The pans are placed in a cold frame and the lights kept closed until the seedlings appear above the surface, and as they increase in size water has to be given carefully, with an abundance of air to make them stocky. When the plants show the second and third leaves it is the custom to prick them off into boxes of similar soil, the plants 2 inches apart, keeping them close for three or four days, and then exposing them by day, but protecting them from late frosts at night. Care is taken to get the plants as sturdy as possible, and when they are 3 inches in height, and before they show signs of sending up a stem, they are planted out where they are to flower, generally in lines 20 inches apart, the plants a foot apart in the lines. The

bed is made of rich soil, and some cultivators prefer strong pig manure to any other, as it appears to impart size to the flowers. Stakes are placed to the plants. In order to have fine blooms for exhibition, a covering of light canvas is employed, not only to ward off hot sun or rain, but to assist the flowers in developing gradually. Plants grown in this way will supply an abundance of bloom from the first week in August until the end of October. As a matter of course, the plants are freely watered when necessary.

The plants do not require continuous sunshine to flower well, but they may be said to revel in cloudy, dry days and abundant night dews. It may be added that under ordinary garden culture the plants should be in rich soil and have an occasional dressing of some artificial manure. It is astonishing how many blooms a plant will produce, and they last for a long time when placed in water. Of varieties there are many. Some are self-coloured, including the new yellow variety shown by Mr. Henry Cannell last summer: some are mottled in two or three colours, and some are rendered parti-coloured by having two distinct zones of colour, but all are very attractive and well deserving of culture. R. D.

#### FLOWER GARDEN NOTES.

HERBACEOUS PLANTS.—The exceptionally mild autumn and early winter, together with a heavy rainfall, have been answerable for early growth on nearly all herbaceous plants, and those who did the necessary amount of division and replanting towards the close of the year were well advised. Of course, such work may be continued, given open weather through January, and those things which most readily submit to division will grow and flower fairly well through the next summer if the work is carefully performed, but in the majority of cases it may be safely asserted that root-disturbance is not advisable when growth is moving strongly. Such things as *Pyrethrums*, perennial *Sunflowers* and *Starworts* will bear late division, for either the root massing is so pronounced that the severance is not severely felt, as with *Pyrethrums*, and in the case of late-flowering plants growth is as a rule proportionately late. In all planting of herbaceous things, especially in the case of late removals, a good surface mulching is necessary. Ground left quite unprotected will be so pulled about by frost as to check the quick formation of new roots, and it will also dry out very quickly given an early spell of sunshine and drying winds. In connection with the general planting of herbaceous things, it may be noted that the question of special places for different families is not always such an important point as suitability of soil and the endeavour when special requirements are mentioned to meet the necessities of the case by making the best of existing conditions. The planter need not despair of doing justice to some particular family even if he has in the ground he is working no place he may think naturally suited to its successful cultivation. It may mean the addition of a heavier or lighter compost to the natural soil, a little excavation, draining, something to raise the plants above the natural level, or a heavy winter mulching, but in any case the desired end is generally effected without a deal of trouble. I remember when starting the naturalisation of *Daffodils* in our pleasure grounds it was considered that the shallow soil resting on sand was likely to be against a long life for the bulbs. A careful examination, however, proved that the sand was of a damp, fairly holding nature, and as this formation is a characteristic only of the higher parts of the grounds, the incomparabilis family were planted here and have done fairly well, whilst the trumpets found a home in stiffer soil and in lower sites.

If any alterations are necessary on lawns they should be put in hand at once if not already done. They may possibly include the enlargement of some beds, the filling up of others, and the removal of any objectionable objects. In the latter case the absolute necessity of dispensing with anything in the way of tree or shrub that is

seraggy and unhealthy and never likely to develop into a nice specimen cannot be too strongly enforced. The argument is sometimes advanced that such things are valuable as rare plants. This, however, does not justify their retention in any prominent place; they should be removed to a hospital in some out-of-the-way corner where they may have a chance of recovering, and their places be filled with healthy plants. The enlargement of beds should be specially considered in connection with those parts of the garden that may lie at some distance from frequented paths and where it is deemed advisable to have a bright display, small beds and dwarf planting being under these conditions worse than useless, and a Grass bank or a belt of greenery decidedly preferable. Such places are suitable for the employment of high-class shrubs, possibly in connection with tall perennials, as, for instance, the double-flowering Deutzia with Delphiniums and Hydrangea paniculata with the hardy Fuchsias. Many of the Star-worts, also the Sunflowers, as Helianthus multiflorus plenus and Soleil d'Or, are also well suited for such positions. In connection with the enlargement of beds it may be noted that even on small lawns a few beds of fair size are always preferable to a host of little beds, the flower gardener can plant to much better advantage, and in all cases a goodly proportion of green carpet between the beds renders the planting all the more effective. If any trees of considerable size are removed from the lawn and it is not deemed advisable to replace them, a portion of the stump may remain to be clothed with some climbing plant, one of the Clematises or Ceanothuses, or a good rambling Rose like Aimée Vibert. The last named where it clothes an old stump of Pinus Cembra and forms a dense bush 7 feet high and 15 feet in diameter is in its season decidedly the most attractive feature in our flower garden. Formal geometrical gardens are now the exception rather than the rule, but if a new design is to be laid down or any alterations are proposed to plans that already exist, the work should be pushed forward when the weather is suitable. Whether the garden is to be cut out on turf or the edges of the beds are to be of Box, with intervening walks, the plan, if somewhat complicated, should be drawn to a scale, and then if the ground is marked out on similar lines the gardener has little difficulty in transferring even the most elaborate designs from paper to the soil. In cutting out and laying turf or Box the work should be accurately performed.

If a decision has not already been made as to the numbers and varieties of tender plants required for summer planting, no time should be lost in doing so; it is useless blaming the propagator for deficiencies unless he knows accurately what is required of him. It may be well at this time to recall the general aspect of the flower garden in 1894 with the view to remember success and failure. Personally I am inclined to give extra prominence this year to Antirrhinums, Fuchsias, and Violas, and to considerably reduce the number of zonal Pelargoniums. The stronger growing varieties of these were a failure in 1894, the damp summer being conducive to rank growth, but very little flower; in fact, all through the sunless time one might visit several beds without finding a properly developed truss. Begonias were considerably better than in 1894, except the very large-flowered varieties, which were much beaten down by the rain. E. BURRELL.

Claremont.

**Variiegated Sweet-scented Tobacco** (*Nicotiana glauca* var. *variegata*). This variegated form of the popular Sweet-scented Tobacco should prove a welcome addition to those who are fond of variegated foliage. It is equal in size to the green kind and the leaves are prettily variegated with white, which will contrast well with other plants.—W.

**Saxifraga ligulata**.—One is sometimes asked to name a plant that will do well under trees. It must be admitted that the choice is limited, and there are but few subjects which flourish under the shade of overhanging boughs. When I was at

Belvoir Castle in the spring of 1893 I could not help being struck with the appearance of *S. ligulata* doing so well under the shade of Yews. It was flowering with great freedom, as it usually does in this position, and it is worth noting as useful for such a purpose.—R. D.

## STOVE AND GREENHOUSE.

### RICHARDIA REHMANNI.

(THE ROSE-COLOURED ARUM LILY.)

A REALLY rose-coloured Arum Lily with flowers the size of those of the common *Richardia aethiopica* would certainly prove a most acceptable and serviceable addition, but, alas! this phenomenal plant still remains to be discovered, and for the present we shall have to be content with the subject of the accompanying engraving, which represents a vigorous example of the new *Richardia Rehmanni*, a true Arum Lily, although differing entirely in aspect and stature from the everywhere familiar Lily of the Nile

*Richardia Rehmanni*. Engraved for THE GARDEN from a photo sent by C. G. Van Tubergen, Jun.

(*Richardia aethiopica*). As shown in the engraving, the foliage of this plant is one of its most distinct characters, being lanceolate in form and resembling the foliage of some of the members of that group of plants, the Scitamineae, to which Cannas, &c., belong. The flowers of the *R. Rehmanni* are of about the size and shape of those of the well-known *R. albo maculata*; in my plants the buds were streaked with chocolate-brown, and the spathes on unfolding were in the inside of a shade of rose colour, as one sees in soft coloured forms of *Lycaste Skinneri*. Contrary to "W. W.'s" statement in his description of this plant on p. 447 of last year's issue of THE GARDEN, the flowers of my specimens retained their rosy colour to the last, the spathes turning to a greenish colour on reaching maturity. This difference is perhaps due to the fact that the plants which flowered at Kew and at Cambridge had been introduced from Natal (between 28° and 30° of latitude); whereas I received my bulbs from a friend living as far north as 24° latitude. My plants are now ripening seed freely, and as the flowers were all

fertilised artificially, I am not without hope of eventually raising some more highly coloured forms. C. G. VAN TUBERGEN, JUN.

**Roman Hyacinths.**—It is very gratifying to find "Grower"—see page 12—referring to the very satisfactory flowering of his bulbs this season, a fact alone which speaks volumes for their general culture. So satisfactory a state of things could not possibly have resulted from anything but thoroughly matured bulbs, in the first place, and, secondly, from none but bulbs of first quality. I had almost said bulbs of "first size," but too frequently in these things mere size does not denote quality. "Grower" thinks it possible to over-estimate the importance of thorough ripening. Here I cannot agree with him. He must remember that though the year 1894 was by no means noteworthy for sun or heat in England, we have not to depend on our own season for the growth of these Roman Hyacinths which we receive each year from naturally warmer and sunnier climes. The very early date at which we receive supplies each year fully illustrates the greater natural warmth and a much earlier season than our own. The all-important period for these bulbous plants resolves itself into the narrow limits of about three weeks, during which the germ of the ensuing season's flower is laid. Provided there is at this particular season a sufficiency of sun and warmth, then all is well, but if this essential—and I regard it as absolute—is wanting, so will the flower-spikes also be wanting in quantity and quality. If "Grower" doubts this, let him secure some of the best Roman Hyacinth bulbs another season as soon as they come to hand, plant them in an English garden and grow them there a full season. In the following year let him force these beside the annually imported ones, and see for himself the difference.—E. J.

**Wallflowers under glass.**—Those who have cold frames to spare during the winter might do worse than fill them with Wallflowers. If the plants are well grown, such early blooming varieties as Harbinger and Early Paris Market will form buds early in the autumn, and with protection will open their flowers during the winter and early spring. After some winters a few dozen Wallflowers cared for in this way are of great use. It not infrequently happens that a severe winter very much retards and sometimes kills Wallflowers in the open air, and then one is glad to be able to gather a few nice heads of bloom from sheltered plants. Bitter winds with bright sun are also apt to prevail in March, and plants protected will then give blooms fine in colour and rich in fragrance. Seed should be sown early in March in the open ground, setting out the young plants as soon as large enough to handle in the most exposed position in the garden. Give them ample space to enable them to make a sturdy growth and well ripen it and lift them carefully early in November. The old-fashioned double yellow Golden Drop is as worthy of a place under glass as many things more in fashion at the present time. Cuttings of this variety root readily. The plants should be grown along in pots in the open air, getting them into 7-inch pots in early summer. They will in this condition bear a little forcing, and will produce large fragrant spikes of bloom quite early in spring.—J. C. B.

**Bouvardias.**—At one time Bouvardias could be well grown within the London district, but now with the great increase in bricks and mortar the fogs experienced during the autumn and winter are far more sulphur-laden than they were formerly, and as a class Bouvardias are the first to suffer under such conditions. They will grow well enough during the summer months, and consequently in the early autumn good flowering examples may be had, which will behave in a satisfactory manner till the fogs come, when a few hours will suffice to transform a house of thriving plants into a mere wreck. The flowers do not suffer to anything like the same extent as the foliage, for every leaf presents such a burnt appearance as if it had been exposed to a fire.

Even on plants that have been so injured the flowers will open fairly well, so that a few years ago when Bouvardias were grown in quantity by our market growers almost in London itself, I have seen a house of them yield a fair return in the shape of cut bloom, while nearly all the leaves had been killed. The difficulty attending plant cultivation in or around London increases every year, and it is no easy matter to keep some plants alive which a few years ago could be grown in a satisfactory manner. Besides Bouvardias, such plants as Pelargoniums will lose a great many leaves, Indian Azaleas will often become nearly bare, and many of the flowers refuse to open properly. Rhododendrons of the Javan group will, if a suitable temperature is maintained, flower well in the winter despite the fogs, but the numerous garden varieties claiming parentage chiefly from the Himalayan *R. ciliatum* and *R. Edgeworthii* cannot always be so thoroughly depended upon, for though in most seasons they bloom well, yet a fog of unusual density will sometimes cause many of the hard prominent flower-buds to drop.—H. P.

SHORT NOTES.—STOVE & GREENHOUSE.

**Bambusa Fortunei foliis aureo-variegatis.**—In Messrs. Peed and Sons' nursery at Tulse Hill this pretty ornamental little plant is grown in quantity, and is very attractive in such a small state. The bright golden variegation is very fine and contrasts well with small Ferns and other plants when used in small rustic vases. For this work and other indoor decorations it is admirably adapted.—W.

**Lapageria rosea** (Nash Court variety).—Undoubtedly the finest variety of this magnificent climber is the one known as the Nash Court variety. In the nurseries of Messrs. Laing at Forest Hill a magnificent specimen in full flower covers a large portion of the roof of one of the houses. It is very free-flowering and robust in growth, the individual blooms being very large and of an intense deep shade of colour.—G.

**Begonia Arthur Malet.**—This Begonia, belonging to the class with ornamental foliage, is very effective for greenhouse decoration. It is of easy culture, requiring during the winter months a temperature of about 55°. In addition to the brilliant display made by the foliage, the plants when in good condition continue to flower as long as they are kept growing. It appears to be a great favourite and likely to hold its own for some time to come.—W. H. G.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 15.

THIS, the first meeting of the year, was not an extensive one; in fact, its extent was appreciably below that of several of its more immediate predecessors. What was lacking, however, in this respect was amply compensated for in the several features of interest amongst the Orchids and other exhibits, notably the Primulas shown by the Reading firm, which gave abundant proof of the care bestowed upon the selection and hybridisation of this most useful winter flower. Of the Orchids, as far as certificates were concerned, it was almost entirely a field day for hybrid *Cypripediums*. Eight of the hybrid Slippers received awards of merit, and others were shown which a few years ago would have easily won that distinction. Several fine forms of *Lælia anceps* were shown from various sources, whilst the earlier of the spring-flowering Dendrobates were present, prominent amongst which were some of the choice hybrids raised at Burford Lodge. A very good plant of *Cymbidium Traceyanum* was exhibited with a spike of about ten of its scented flowers. This is the first plant that has been shown of this Orchid since that from The Dell collection, although one other from the same source as the present one was lately sold by auction in the City. The work of both the floral and the fruit com-

mittees was comparatively light, particularly that of the latter, by whom no awards were made to any new productions.

Orchid Committee.

Numbers of small exhibits were exhibited here several of which were cut examples, regard being had no doubt to the wintry weather of the past week or two.

A first class certificate was awarded to—

**LÆLIA ANCEPS CRAWSHAYANA**, of which a very fine spike of half a dozen blooms was exhibited. It is quite a major form of the type, having large flowers with unusually broad petals and long sepals, which were suffused with a deep rosy purple tint, deeper than in the species, the lip at the same time being well marked with rich violet-crimson. From Mr. De Barri Crawshay, Rosefield, Sevenoaks.

Awards of merit were voted to—

**CYPRIPEDIUM J. H. BERRY.**—A cross between *C. Harrisianum* superbians and *C. concolor*, the influence of the latter parent being most apparent in the contour of the flower, the petals of which are very broad, the lip large, also the dorsal sepal, the markings being rich purple of divers shades, the darkest colour being seen in the upper sepal, a shading of pale green helping to set the flower off to better advantage. From Messrs. Sander and Co., St. Albans.

**CYPRIPEDIUM MME. JULES HYE.**—Undoubtedly a hybrid, although the parentage was not given. It has the character of *C. Leeanum* in a measure, also of *C. Spicerianum* in the form of the dorsal sepal; the flower was remarkable for its bold and massive appearance, as well as its rich colouring. The lip was extra large and of a dark bronzy shade, the dorsal sepal also large, reflexed at the base and marked with dark vinous purple, a darker line of which ran through the centre, the base being green; the petals were broad and rounded at the extremities, bronzy green, with darker lines. From M. Jules Hye, Ghent.

**CYPRIPEDIUM NITENS SUPERBUM**, of which hybrid it is a very superior form with larger and brighter flowers, the dorsal sepal being finer and more distinctly marked, whilst both the sepals and petals were of a deeper colour. The plant to which this award was made bore five large flowers, the growth being vigorous. From Mr. W. Cobb, Dulcote, Tunbridge Wells. A smaller plant was also shown by Messrs. Sander and Co.

**CYPRIPEDIUM NORMA** (*C. Niobe* × *C. Spicerianum*).—From such a cross this could scarcely fail to be a very handsome and distinct seedling; the dorsal sepal showed the influence of the latter parent in shape, being shaded with vinous purple and darker lines on a white ground; the petals resemble those of *C. Niobe*, being drooping, as in *C. Fairricanum*, one of the parents of the latter hybrid. These are shaded and veined with dark purple; the lip is of a dark bronzy shade. From Messrs. J. Veitch and Sons, Chelsea.

**CYPRIPEDIUM MIMOSA SUPERBIENS** (*C. Arthurianum* × *C. Spicerianum*), in which hybrid *C. Fairricanum* was again traceable, it being one of the parents of *C. Arthurianum*, the petals possessing the characteristic drooping tendency, but much darker in colour, a dark bronze-purple on a light yellow ground; the lip is that of *C. Spicerianum*, so also is the dorsal sepal in shape, being large and marked with dark purple in spots and lines, the base being green, the broad margin white. From Messrs. J. Veitch and Sons.

**CYPRIPEDIUM HENRY GRAVES, JUNR.** (*C. Lawrenceanum* × *C. Marshallianum*?).—A very distinct and in some respects singular hybrid, the lip creamy yellow and rather small; the dorsal sepal has the features of the former parent, with much of its colouring, but more diffused, the petals being darker and sparsely spotted. The plant shown bore evidence of a vigorous constitution. From Mr. Henry Graves, Orange, New Jersey, U.S.A.

**CYPRIPEDIUM MRS. FRED HARDY** (*C. superbians* × *C. bellatulum*), to which in a measure been imparted the form of the latter parent, with

its broad petals and spottings of a similar colour; the lip is that of *C. superbians*, but if anything smaller, with bronzy veins and greenish white base; the dorsal sepal is very distinct, with dark veins and lines, a sturdy looking and very promising hybrid. From Messrs. Sander and Co.

**CYPRIPEDIUM MADAME GEORGES TRUFFAUT** (*C. ciliolare* × *C. Stonei*).—A noble-looking and very fine hybrid, with much of the features of *C. Morganæ*, but darker in colour throughout. The spike bore two well-developed flowers. The influence of *C. ciliolare* is most apparent in the lip and in the deeper colour, whilst *C. Stonei* is clearly seen in the pointed dorsal sepal which is of a dark bronzy-purple in lines and spots on a light ground. The petals are broader than in *C. Stonei*, but of the same character, being also much darker in colour. From Messrs. Sander & Co.

**ODONTOGLOSSUM NEBULOSUM CANDIDULUM.**—A very beautiful form of this good old Odontoglossum, being most distinct with its milky white flowers. From Mr. Frederick Hardy, Tyntesfield, Ashton-on-Mersey.

Botanical certificates were awarded to *Maxillaria ochroleuca*, a very pretty species with narrow sepals and petals creamy white in colour, with a deep golden lip, and to *Dendrobium hursigerum* album, a white form with small flowers densely packed in the short spikes. Both of these were shown by Messrs. Sander & Co. *Dendrobium Wattianum*, a very pretty species of extremely slender, but erect growth, with numbers of terminal spikes of transparent white flowers some 3 inches in width, with a golden blotch on the lip which is deeply serrated (worth an award of merit), and *Dendrobium dicuphum*, a very beautiful Orchid, and one that is quite a miniature of *D. Phalaenopsis Schroderianum*, having all its features and growth, the flowers being about 1 inch across, pure white, with deep purple veins in the throat, were also given botanical certificates. Both came from Sir Trevor Lawrence. *Cypripedium Boissierianum*, one of the *Selenipedium* group, with pale greenish-yellow flowers, more singular than beautiful, was also given a botanical certificate. From Mr. Thomas Statter.

Other Orchid exhibits were numerous, although not of an extensive character. Mr. F. Hardy had a good variety of *Odontoglossum crispum*, with a long spike of light-coloured flowers; also cut blooms of *Lælia Cattleya Pallas superba*, one of the finest of the recent Veitchian hybrids, clearly showing its relationship to both *Lælia crispa* and *Cattleya Dowiana*. Also from the same source came a hybrid *Cypripedium* (*C. Boxalli* × *C. villosum*) of intermediate character, but darker; *Cattleya Percivaliana*, of which an extra fine variety was shown, with broad petals and a dark crimson-purple blotch on the lip (a fine form); *Cypripedium Swinburnei magnificum*, a recently certificated hybrid, better in this instance than when the award was made; and *Cypripedium Bellina*, another hybrid, but not sufficiently distinct. Mr. Ingram, Elstead, Godalming, showed *Cattleya Percivaliana* (?) alba, which bore more resemblance to *C. Trianae* in the formation of the lip; nevertheless, a beautiful variety. From Mr. Cobb came *Cypripedium Boxalli* (Cobb's var.), and one with much darker colouring, with lustrous, almost black markings, notably in the dorsal sepal. Sir Trevor Lawrence had a small, but choice selection, chief amongst which were several hybrid Dendrobates, the result of crossing *D. Ainsworthii* and *D. Fendlyanum*, in all of which the colouring was much softened through the influence of the latter. These comprised *D. chrysoideum*, with large flowers with a golden disc upon the labellum, further enhanced by a dark crimson centre; *D. xanthocentrum*, having more old gold colour on the lip, otherwise paler; also *D. xanthocentrum* var., with even less colour, but with broader sepals and petals, a distinctly beautiful form; *D. Hebe*, having extra large blossoms, the lip being broad, with pale golden centre and tipped with palest purple, the sepals and petals white, with similar shading at the points; and *D. pallens*, a particularly fine form, with pure white sepals and petals, very

faintly tipped with pale purple. These hybrids showed their more distinct relationship to *D. nobile*, one of the parents of *D. Ainsworthii*. *D. burfordense* (*D. Linawianum* × *D. aureum*), the flowers of which were suffused with lilac-purple, was included. The Burford Lodge var. of *D. nobile*, with dark blotches on the two lower sepals as upon the lip, was also included; also *Epidendrum polybulbon*, a small, but very interesting species to which a cultural commendation was awarded. *Laelia autumnalis alba* was represented by two fine spikes of its charming white flowers, showing the faintest flush of palest purple. *Phalanopsis Aphrodite*, *P. leucorrhoda*, with faint flush of rosy pink, and *P. Schilleriana* were present in cut spikes, and of *Masdevallia Courtauldiana*, a small, but profusely flowered example was shown, its pale lilac-purple flowers being very distinct. Mr. Lutwyche, Beckenham, staged *Cypripedium sylvetense majus*, one of the *insigne* race, but with smaller, although distinctly marked flowers, also *Cypripedium insigne montanum*.

From Lord Rothschild's collection at Tring Mr. Hill brought a marvellously fine spike of *Phalanopsis F. L. Ames*, one of the finest of hybrids, with seven expanded flowers and as many buds to open. The sepals and petals are pure white, the lip suffused with reddish purple. To this a cultural commendation was most deservedly awarded. From Mr. Forster Alcock came a plant of that singularly coloured Slipper, *Cypripedium tonsum*, a pale-coloured species with a bold, well-formed flower. Messrs. J. Veitch and Sons showed another hybrid *Cypripedium* in *C. Eson* (*C. Druryi* × *C. insigne*), the former parent having tended to deepen the colouring to the flower, the form of which partook of *C. insigne*. Mr. Ashworth, Harefield Hall, Wilmslow, Cheshire, had cut flowers of several fine forms of *Laelia anceps*, notably *L. a. Amesiana*, an extra fine form, with broad petals and distinct markings. *Zygopetalum Mackayi superbum* came from the same source, and that fine old hybrid Orchid, *Laelia exoniensis*, of which four good flowers were shown. It is not often one sees this one of the first hybrids. Messrs. Sander and Co., in addition to their certificated plants, had several others, chief amongst which were some very choice forms of *Laelia anceps*, the white varieties in particular, the best amongst which was *L. a. Sanderiana*, with the purest of white sepals and petals, the lip having a rich violet-purple blotch with dark lines in the throat, the flowers of extra substance. *L. a. Hollidayana*, another fine white form, has the lip with lighter markings and only a faint trace of purple; this is evidently a very distinct and free variety. *Pescatorea Klabochorum* was represented by one plant bearing a fine large flower. *Platyclinis pallida*, with very sweetly-scented creamy white flowers on large slender spikes, most attractive by reason of its perfume; *Cycnoches peruvianum*, a small growing species, both singular and interesting; *Odontoglossum mirandum*, with pale chocolate sepals and petals margined with greenish yellow; the distinct and fine hybrid *Cymbidium Winnianum*, bearing three spikes of considerable length, the sepals and petals of a soft light yellow or straw colour, the lip white with pale crimson spots, and *Phaio-Calanthe Arnoldia*, a bi-generic cross of distinct features, the flowers creamy white and rosy purple, were also included. *Cypripediums* were represented by very fine forms of *C. Leeanum*, as *C. L. James Hamilton*, with its large pure white dorsal sepal, quite in contrast to the darker sepals and deep bronzy lip; *C. L. virginale* is another very superior form with light coloured flowers of large size; *C. Lynchianum*, with some of the features of *C. Lathamianum*, but with more old gold suffusion in the flowers, had fine large flowers, the dorsal sepal reflexed with incurved edges. *C. nitens superbum* was also shown here (see certificated plants). *C. Calypso* (Oakwood var.) was shown well. This is a markedly superior form, with darker dorsal sepal and a fine lip; *C. miniatum*, quite intermediate between *C. Curtisii* and *C. insigne*, its parents, is very distinct in its features; *C. Ridolfianum*, another distinct hybrid, with pale greenish-yellow ground and dark bronzy-

crimson lines on sepals and petals, has the dorsal edged with white. *Odontoglossum crispum* and *O. Pescatorei* were both included. Mr. Statter had *Cypripedium nitens* in good condition, *C. Pariesianum* (*C. Boxalli atratum* × *C. Argus*), the petals retaining the fine distinct spotting of *C. Argus*, the lip bronzy-green, and the dorsal sepal very dark maroon, with light green edges; *C. Euphrosyne*, a form of *C. Lathamianum*; also *C. Leeanum aureum*, with much more of the golden colour apparent in the flower, a fine variety. This was the result of crossing *C. Spicerianum* with a yellow *C. insigne*. From Mr. Prewett, Swiss Nursery, Hammersmith, came a very healthy plant of the at present extremely rare *Cymbidium Traceyanum*. The plant in question bore one good spike with fine blooms, not so large or so vigorous as Baron Schroder's example shown late in 1894, but identical with it. This is the second plant that has flowered with Mr. Prewett, being part of a purchase that was presumably *C. Lowianum*, the growth being but slightly different therefrom. *Cymbidium Traceyanum* does not, it is stated, come from the same locality as *C. Lowianum*; hence it is possible some more of the former may yet be forthcoming. A grand spike of *Phalanopsis Aphrodite* from an unknown contributor was shown with fourteen large blooms.

#### Floral Committee.

There were not many exhibits before this committee.

A first-class certificate went to each of the following:—

**LACHENALIA QUADRICOLOR MACULATA.**—Flower-spikes of this very charming *Lachenalia* came from Mr. F. W. Moore, of the Glasnevin Botanic Gardens. It is a robust and handsome variety, the flowers produced freely on the scape and individually rich in colour. The extreme base is orange, varying to a reddish tone, the sepals deep green, also the petals, which have an apex of deep purple-crimson. *L. quadricolor*, the type, is a well-known species, synonymous with *L. tricolor*. It is a pity that *Lachenalias* are not more grown. There are many good kinds for colour in cultivation.

**RHODODENDRON PONTICUM FOLIOS-PURPUREIS.**—This is a very handsome shrub, similar to the type in growth, but the foliage is almost of a deep crimson-brown shade, very rich, decided and welcome. With the winter sun shining upon it such a shrub would create a rich colour picture in the garden. There is no doubt about its distinctness and the beauty of its colouring. From Messrs. Wm. Paul and Son, Waltham Cross, Herts.

An award of merit went to each of the following:—

**CHINESE PRIMULA GIANT ROSEY QUEEN.**—This was one of the many beautiful varieties in the collection of Primulas shown by Messrs. Sutton and Sons, of Reading. The present variety is very handsome, the individual flowers large, waxy and delicate rose, with greenish-yellow eye, the plant being free both in growth and bloom, with a well-built-up truss, whilst the leafage is distinctly Fern-like.

**PERSIAN CYCLAMENS.**—An award of merit was also given to Messrs. Sutton & Sons for their fine strain of Cyclamens, comprising a variety of colours. Purple Queen has, as its name suggests, purplish flowers, but we do not care for this so much as one named Salmon Queen, to which we think the award more directly applied. This is a sturdy, free-blooming plant, with neat, well-formed flowers of a carmine or salmon-rose shade, very clear and distinct.

**CHRYSANthemum JEANETTE SHEAHAM.**—This was given this award as a late decorative variety. It is very free, the flowers of the Japanese character, but of a yellow colour, deepening in the centre. It will doubtless be useful as a Japanese flowering kind, but is not particularly uncommon in other ways. Exhibited by Mr. D. Sheaham, Hartfield Road Nursery, Wimbledon.

**ROSE MRS. PIERPONT MORGAN.**—This is an American variety, the flowers exhibited having

been sent from America, this accounting for their damaged petals. It is described as a sport from Mme. Cusin, and has much the aspect of that beautiful Rose, the petals forming a bloom of charming expression, whilst the colour is deep rose. When, however, the blooms are fresh, the tint may be clearer and more, so to say, glistening. A great feature is its fragrance, even in the blooms shown, this being as delightful as in any Tea Rose we know, a precious trait not always considered by raisers of new kinds. Shown by Mr. John N. May, Summit, New Jersey, U.S.A.

**CHRYSANthemum L. CANNING.**—This was shown under the name of Heine's White or similar title, but the above is the correct designation. A lovely plant full of bloom was shown by Mr. Thomas, of the Royal Gardens, Frogmore. It is a Japanese variety, the flowers full, very freely produced and white, touched with rose.

There were very few miscellaneous exhibits. The only medal given was a silver one, which went to the large and interesting display of the various types of Chinese Primulas from Messrs. Sutton and Sons. The double varieties were extremely beautiful, the plants well grown and the flowers of refined colours. *Alba magnifica* is white, touched with rose, and the double *Heliotrope*, a soft heliotrope colour, less pronounced, but quite as pleasing as the double blue, which is a lovely shade, not slaty or purple, but clear and welcome. *Double Carnation Flake*, the flowers white, flaked with light purple, a very free-blooming variety, and such single kinds as *Pearl*, white, with yellow eye; *Giant Pink*, a large handsome flower, white, with suffusion of pink; *Grenadier*, brick-red, a bright telling colour, were also good. Messrs. H. Cannell and Sons, Swanley, Kent, showed a few of their fine single Chinese Primulas, as *Neatness*, a delicate rose and white flower; *Duchess of Fife*, soft rose; *Kentish Purple*, deep crimson-purple, the beautiful *Eynsford White*, Cannell's Pink, a distinct and attractive flower of this colour, and *Swanley Yellow*, a near approach to a true yellow variety, the flower of this colour save for a rather broad creamy white margin. Messrs. Cannell also had a bunch of that fine *Canna Queen Charlotte*, very good for this season. Messrs. J. Laing and Sons, Forest Hill, S.E., exhibited a basketful of *Nicotiana affinis variegata*. The leaves are abundant, glaucous, margined with creamy white. *Carnation Jane Collins*, shown by Messrs. Collins Bros. and Gabriel, Waterloo Road, S.E., appears the same as *Will Threlfall*. It is, we believe, supposed to be a cross with a tree variety and one of the Malmaison types, but there was nothing to indicate such relationship. The flower is of fair size, clear yellow, and scentless, the plant strong in growth. Mr. Moore sent from Glasnevin *Dematobotrys Saundersi*, an interesting plant with an umbel of tubular reddish flowers, and *Hippeastrum alicium grandiflorum*, which has far larger flowers than the type. Mr. H. Howell, Queen's Nursery, Hammersmith, had *Pteris tremula* Howelli, a very graceful Fern with dense pinnae.

#### Fruit Committee.

A large number of members was present at this the first meeting of the year. Messrs. Cheal and Sons, Crawley, Sussex, staged seventy dishes of Apples and about ten of Pears. The Apples were firm, well coloured, and not extra large. There were some very nice examples of *Frogmore Prolific*, *Lord Derby*, *Sandringham*, and *Mère de Menage* in baskets, with good single dishes of *Blenheim Orange*, *Schoolmaster*, *Cellini*, *Lord Burghley*, *Hollandbury*, and *Bismarek*, which appears to have done well in most places, a wet season suiting it. The *Crown Apple*, *Annie Elizabeth*, and *Prince Albert* were the best cooking varieties. Among the dessert kinds, *Claygate Pearmain*, *Cox's Orange*, several varieties of the *Russets*, *Ribston Pippin*, the new *Atalanta*, and *Swedish Reinette* were the best. The best Pears were *Chas. Cogne*, a large nice-looking fruit and very late, *Duchesse de Nemours*, *Catillac*, *Verulam*, and *Uvedale's St. Germain* (silver Knightian medal). Messrs. Laing and Sons,

Forest Hill, staged a smaller collection nicely arranged with Ferns in pots, the best fruits being Bismarck, Brabant Bellefleur, Tower of Glamis, Gloria Mundi, Lord Derby, Striped Beaufin, Sandringham, Flower of Kent, Lady Henniker, and Royal Russet (silver Banksian medal). A very nice dish of Tomatoes was sent by Mr. J. Gray, Bodorgan Gardens, Anglesey, N. Wales. It is a bright looking fruit, a cross between Prelude and Ham Green, and of good flavour. The committee would like to see it in March. Some very good Rhubarb named Tottenham Early came from Mr. W. Gradwill, Manor Road, Tottenham. This is a promising variety, bright pink with the colour running through the stalks, which are of a nice size. The committee thought it a good variety, and wished it to be sent to Chiswick for trial.

**Royal Botanic Society.**—At a meeting of this society on Saturday last, a motion by Mr. Rubinstein as to the admission of the public to the Gardens on payment was discussed. The motion on being put to the vote was lost by a large majority.

**United Horticultural Benefit and Provident Society.**—The quarterly meeting of this society was held at the Caledonian Hotel on Monday evening last. Mr. Joseph Wheeler presided. Twelve new members were elected and four others nominated. Two deaths have occurred during the quarter, one being that of Mr. Charles Collins, who died suddenly on December 26 at Forest Gate Railway Station. The widow being left in distressed circumstances and in very delicate health, the committee granted her £10 from the Benevolent Fund in addition to the small amount standing to her late husband's credit. The other member who died was Mr. Arthur Loeke, of Woking, after seventeen weeks on the sick fund. The amount standing to his credit was paid to the widow according to rule. The proposed increase of sick pay was discussed and a requisition signed by members present for a special meeting to be called in March for alteration of rule bearing on the point. The treasurer was instructed to invest £400 in West Bromwich Three per Cent. Stock.

NOTES OF THE WEEK.

**Anchusa Barrelieri variegata** will, I think, prove to be one of the best plants of this year, very free growing, in fact the new leaves are already well developed; they are ample in size, broadly margined with creamy white, the flowers of the most intense blue. From its habit of commencing to grow in the autumn, it has, as it were, two distinct seasons, which together form a long one. — T. SMITH.

**Cattleya exoniensis.**—A good many Orchid growers of the present day may not possibly remember when this extremely beautiful hybrid was first brought before the public. It is even now far from plentiful, and I note that its raisers, the Messrs. J. Veitch and Sons, although they catalogue, do not place a price against it. This is sufficient indication that there is not a large stock. It was shown in a cut state at the last R.H.S. meeting, also at a late meeting in the past year. I recollect a large plant of it being sold some twenty years or so back; this was afterwards broken up for stock, with what after results I do not know. In its labellum one can clearly see its affinity to *Laelia crispa*, the impress being left in the beautifully crisped edges — H. A.

**Hybrid Dendrobis.**—Anyone who was interested in these Orchids could not, I think, fail to note the very charming hybrids shown at the Drill Hall on Tuesday last by Sir Trevor Lawrence. I refer more particularly to those which have as their parents *D. Findleyanum* and *D. Ainsworthi*, the latter itself also a hybrid. There were several of these shown which were quite distinct, but in all the refinement and soft colouring of *D. Findleyanum* was most noticeable. The growth was also

more sturdy in the way of *D. nobile*, but of paler colour. This cross has beyond doubt proved to be a most satisfactory one; hence it is worth noting that *D. Findleyanum* should in the future be used in conjunction with other hybrids or species. The hybrids above noted are of very free growth. — H. A.

**Phalænopsis F. L. Ames** (hybrid).—With such a wealth of hybrid *Cypripediums*, *Lælias*, and *Cattleyas*, it is quite a pleasing change to note this hybrid *Moth Orchid*. The spike (a cut one) in question was an exceedingly fine one with fourteen flowers and buds, about half of which were expanded, the largest of these being quite 3 inches in diameter. The sepals and petals are pure white and more pointed than in *Phalænopsis Aphrodite* or *P. grandiflora*, from both of which it also differs in the colouring of the labellum, wherein reddish purple prevails. This fine spike came from the Tring Park collection, where for many years these Orchids have been grown most luxuriantly under the charge of Mr. Hill. It is named after the late Hon. F. L. Ames, who had a superb collection at North Easton, Massachusetts, U.S.A.—H. A.

**Olearia Haasti.**—"G. H. A." is quite right in supposing this to be a good seaside plant. For many years I gardened under difficulties in the storm-vexed Isle of Thanet. My cottage stood some 40 yards back from the sea, over which the wind came howling straight from the North Pole heavily laden with brine, which used to burn up even the Japanese *Enonymus*. The plants that best bore the attacks of this fierce enemy were *Olearia Haasti*, *Rosa rugosa* and *Escallonia macrantha*. Double *Gorse* stood well. The only tree that held its own was the evergreen Oak, which thrived splendidly. The possibilities in the way of trees and shrubs were few, but what compensation in the brilliancy of the flowers! Bloom and colour were splendid, and, above all, the *Carnations* stood out in peerless beauty.—M.

**Campanula Raineri.**—Surely many of your readers will agree with me in thinking that what has been a useful discussion in the way of clearing up some doubtful points of nomenclature is degenerating into personalities. If we are to have a discussion on the practice of uprooting wild plants for trade purposes, by all means let us have it kept clear from the strictly limited question at issue. We have already had a considerable amount of information regarding *C. Raineri* and the plant which passes in some gardens as such, and if no one has any more to tell us about it, another season may help to clear up any doubtful points which may remain. I do not want to introduce any names of trade dealers, but in justice to those abroad I should like to say that with me the losses among carefully packed plants from foreign nurseries do not exceed those among similar plants from English nurseries.—S. ARNOTT, *Carsethorn, Kirkcubbin*.

**Verbascum phœniceum.**—Mr. Archer-Hind in your last number speaks of this Mullein as never having ripened seed in his garden for more than fifty years and of his never having met with a white variety of it. Here, in my garden, it is, after *Chaixi* and *philomoides*, the most prolific of seedling Mulleins, numbers of self-sown plants coming up yearly in my borders, and amongst these, which vary very much in colour, are occasionally pure white forms. These latter, I notice, have only been produced on the stoniest parts of a rockery. With me *V. phœniceum* has never crossed with other species, although it has been in flower contiguous to other Mulleins over and over again. — F. M. BERTON, *Highfield, Gainsborough*.

— In all probability before this reaches you someone will have sent you a note regarding the remarks of Mr. Archer-Hind in THE GARDEN of January 12 (p. 31), but a few words may still be acceptable. On reading Mr. Archer-Hind's note, I referred to the illustration of *V. phœniceum* on p. 519, and for its size it is a faithful representation of that species, and not of *V. nigrum album*. Your correspondent, "J. E. N." is correct enough in speaking of a

white variety of *V. phœniceum*. I have had this in my garden for several years, my first plants having been raised from seed purchased as *V. phœniceum hybridum*. The seedlings varied considerably in colour, some pinkish coloured and the white ones being particularly pleasing. In form and habit they show no trace of hybrid origin, and only appear to be seminal varieties. These plants ripen seed here every year, and sow themselves so freely as to become rather troublesome in the garden. From the exposed position of my garden I find it difficult to stake this *Verbascum* in such a way that the sticks are hidden, so that its appearance is much spoiled. On the other hand, *V. nigrum album* stands up well with very little assistance in the way of staking.—S. ARNOTT, *Carsethorn by Dumfries, N.B.*

**Sweet Peas.**—I have very much pleasure in confirming what Mr. Burrell writes regarding the newer varieties of Sweet Peas. In addition to those mentioned by him I would strongly advise those who have the opportunity to try the following varieties: *Her Majesty*, a rich, rosy-pink variety, strong and robust in growth, one of the best for cutting; *Dorothy Tennant*, a beautiful shade of lilac-mauve; *Firefly*, the best of all scarlets; *Emily Henderson*, the well-known white of American origin; *Bronze King*, coppery bronze, with white wings; and *Blushing Beauty*, distinct, a soft pink shade. *Lady Penance*, a beautiful rose colour, and *Lady Beaconsfield*, a combination of yellow and rose, are two very recent introductions which are particularly charming. I made these notes last year after trying about thirty sorts. In Scotland it is my experience that Sweet Peas, if sown during January in pots, can be had in bloom quite a month earlier than those sown outside in the usual way. At planting-out time it is necessary to give the young plants slight protection until they become inured to the exposure.—W. M. CUTBERTSON, *Springfield, Rothsay*.

**Dendrobium Phalænopsis Schröderianum.**—The more we see of this most beautiful Dendrobe the more are we charmed with it. The great diversity of colours is one of its peculiar charms; these are exceedingly various, it being a difficult matter to know which to admire most, those with the deep richly coloured tints of purple and purplish rose or the delicately beautiful lighter tints wherein the ground colour of pure white is so softly suffused with rose or purple; there are also those with quite intermediate tints. It is most satisfactory to find that this *Dendrobium* is such a very free-growing plant, enjoying an abundance of moisture and heat, it is true, when growing. I recently noted at Messrs. Sander's establishment an immense importation, many of which had bulbs of unusual length, whilst nearly every one was crowned with three or four remnants of flower-spikes, sufficient indication of its free flowering. Not even the good old *Dendrobium nobile* can hope to hold its own against this formidable rival, which is already fully entitled to the topmost place. The flowers last for a long time in the best possible condition, whilst the spikes, by reason of their length, further extend the season. I find that a drier atmosphere and a slightly cooler temperature suit this Dendrobe when in flower. When in growth my plan is to suspend the plants from the roof. I note also that teak baskets seem to suit better than shallow pans. Abundance of water can be more safely given to basket plants than to those in pots. — ORCHIDS.

**The weather in West Herts.**—The recent cold spell lasted from December 30 to January 13, or for fifteen days. During this period the greatest cold experienced during the daytime occurred on the 11th inst., when the thermometer in the screen, 4 feet above grass, at no time rose above 26°. During the two previous nights a thermometer exposed on the surface of the snow registered 18 of frost. Both of these readings are the lowest recorded as yet this winter. Although the last three days have been comparatively mild, the ground both at 1 foot and 2 feet deep is at the

present time as cold as at any time during the frost. At 2 feet deep the temperature is now 4°, and at 1 foot deep 2° above the freezing-point. The latter reading is 2° colder than the January average for the previous nine years. On Saturday night the heaviest fall of snow of the present winter took place, the average depth on the ground on Sunday morning being 3½ inches. By Monday a great deal had melted, so that the ground was not even completely covered. During the past week sunshine was recorded on but one day (Sunday), and even then the sun shone out for only about an hour.—E. M., *Berkhamsted*.

#### Proposed national vegetable exhibition.

The report of the provisional committee was presented at a meeting of the general committee, Mr. Briscoe Ironside in the chair, at the Royal Aquarium on the 15th inst., about thirty members being present. The committee stated they had failed to obtain the consent of the Crystal Palace directors to hold the show there in September, and they had approached the Royal Aquarium directors with that object. The latter agreed to assist and grant space for a show the second week in September. Several leading firms had promised liberal sums to the prize list. Messrs. Sutton declined on the ground that their promise of help was conditional on the show being held at the Palace, and others wished for more information. The secretary *pro tem.*, Mr. A. Dean, stated that about £200 would be required to meet the expenses of such an exhibition, and of this about £40 was promised. Mr. A. Dean stated he must resign the office of secretary, as he found he could not give the time to the work, and he only accepted it at first with the intention of giving the movement a start. Mr. Richard Dean was then proposed, but was obliged to decline the office. Mr. Molyneux was finally selected, but when the duties had been defined, Mr. Harrison, Leicester, thought it would not do to have a secretary so far away from the work, and he thought it best to give up the exhibition this year and have a larger next. Mr. Millard, representing Messrs. Sharpe, Lincoln, suggested an adjournment for a month. Mr. Cannell, Swanley, seconded. It was considered that by that time the committee would be in a position to know how the various seed firms had replied to the circulars sent them.

#### GARDEN SCREENS.

SCREENS in London gardens are somewhat desirable, and especially so when the backs of one line of villa residences abut upon those of another, and where that is so anything like privacy is practically impossible. But it is possible to provide screens, and that, too, at no great cost. A wooden lattice fence can be put up with diamond shaped openings, and if the light framework does not touch the ground, and so contract rot from the wet soil, and it be painted with one or two coats of green paint, it will last for a considerable time, or a framework can be made by fixing two uprights, one at each end of the proposed line of screen, and then stretching a few lengths of galvanised wire between the two uprights. Other designs will no doubt suggest themselves.

Now comes the question what to plant against such a screen. Last year I saw one constructed with galvanised wire that had been planted alternately with the common Virginian Creeper and the blue Clematis Jackmani. When well established the shoots of the Clematis, with a little training, ran through those of the Virginian Creeper and made an excellent summer screen. Both subjects being deciduous, there was, of course, an absence of foliage during the winter, but there were many leafless shoots notwithstanding, and then the screen was not so much required in winter as in summer. The *Colchic Laurel* or *Aucuba japonica* will make a good evergreen covering, the shoots being loosely tied in and displayed so as to cover as much space as possible; or a vigorous growing common Ivy may be used, only that large plants in pots would be necessary to ensure a rapid covering, as young plants of Ivy are of somewhat slow growth until they get

well established. The fact that I am dealing with suburban villa gardens in London somewhat narrows the area of selection, as one has to consider what is likely to succeed in somewhat crowded districts. R. D.

#### REGISTERING FROST.

IN order to get the correct register of frost at night, should the thermometer be exposed or shaded in any way? I am in the habit of hanging mine horizontally about 3 feet above the surface of the ground without any covering whatever. Is this right?—G. J.

\* \* On a clear calm night the greater the amount of sky from which the bulb of a minimum thermometer is shielded and the greater the distance the instrument is from the ground the higher will the reading be. The nature of the surface over which the thermometer is suspended will also influence it. Therefore, meteorologists, in order to obtain comparable results, place their thermometers in a thermometer screen which, while admitting the air freely, shuts off entirely direct radiation both from the sky and ground. Moreover, the screen is always placed on an open lawn and the thermometers suspended 4 feet above the Grass. This plan does not of course give the degree of cold to which vegetation is subjected on a frosty night, but is the only way to obtain what "G. J." asks for—the correct register of frost. They also place an unmounted thermometer on the surface of an open piece of lawn, with the Grass kept at all seasons quite short. These are the readings I prefer quoting when writing for gardeners, but they are not as strictly comparable as those taken in the screen. But for all practical purposes, "G. J.'s" method would be almost equally satisfactory for comparing the lowest night temperatures between one place and another if all gardeners would agree to adopt precisely the same plan, and be careful to set their thermometers right when they found any spirit had evaporated into the upper part of the tube.—E. M., *Berkhamsted*.

**Granite dust for the garden.**—I notice that certain advertisers are recommending the use of granite dust for garden use. Will any of your readers tell me if they have any experience of it in this way?—J. E. I.

\* \* In making the rock garden at Chiswick some years ago we used this largely for mixing with the soil in which the various alpine plants were put. It seemed to suit them remarkably well, as they all did well in it, keeping as it did the soil porous, and admitting of plenty of water being given during a dry season. It also, when sprinkled over gravel that does not bind well, tends to solidify it.—Ed.

**Competition in garden design.**—The worst feature of nearly all our public parks and gardens is their winding belts of trees and shrubs. The competitive system of offering a substantial premium for the most picturesque plan wherever a new place has to be laid out and planted is a serious hindrance to reform. All sorts of pretty plans may be drawn on paper, but what is tolerable on an ordinary plan becomes impracticable when the ground comes to be dealt with. The proper place to design the ornamental features of park or garden is upon the ground itself, and there alone should they be determined with all the factors that influence the work before the eye. If there must be a plan for the guidance of those to whom the details of the work are entrusted—and this much is often necessary—it is easily prepared from the actual thing as arranged upon the ground itself. This conventional preparation of the garden on paper is beginning at the wrong end. The designer is so apt to be influenced by the things he thinks pretty as to apply them indiscriminately, and they become virtual trademarks which indicate plainly who was the author of the work. Next to simplicity as regards the arrangement of walks and roads the all-important point for consideration is the permanent growth of the trees and shrubs that are to adorn the

place. On the plan we see trees like beehives and sugar-cones, but the less there is of such ugly forms in gardens the better. The great fault, however, is that all go in for the same style of shrubbery, which begins by planting a medley of many things for immediate effect and ends in a confused tangle, in which the gross and common overpower the choice and pretty, or the pruning knife is brought to the rescue to perpetuate the beehives and cones.—A. H.

#### OBITUARY.

##### WILLIAM THOMSON.

WILLIAM THOMSON, of Clovenfords, whose death on Saturday, January 12, at the age of eighty-one I regret to announce, was, I believe, a native of Roxburgh, but settled early in life with his father in Mull. Afterwards he went to Bothwell Castle, then a noted place under the management of a well-known gardener, Mr. Turnbull. Mr. Marnock and Mr. Thomson were, I believe, at Bothwell together. From there Mr. Thomson went to Wrotham Park, Middlesex, where he grew fine fruit and carried out numerous improvements. From Wrotham he went to Dalkeith Palace, where he remained about sixteen years, when he left to manage the famous Clovenfords Vineyard, which he had founded and built. Mr. Thomson was a man of rare natural ability and force of character, kindly in all his personal relations, and a thoroughly practical and enthusiastic gardener. He was a very frequent contributor to the gardening press at one time, and his vigorous articles on heating by hot water in the *Scottish Gardener* about 1860 did much to awaken attention to the subject and improve the system of heating hothouses and other buildings. He was the inventor of the treble retort boiler, one of the best boilers for burning coal yet tried. He was, indeed, a competent hot-water engineer, and he taught some of the young men, whom he turned out, to be as competent as himself in that line. Thomson's book on the Vine has gone through several editions. He was a well-known figure at all horticultural exhibitions and meetings in Scotland up to the last, and will be greatly missed. He trained and sent out from Dalkeith and Clovenfords many young men as head gardeners to important places in different parts of the kingdom, and was presented with a handsome testimonial by a number of his earliest pupils some few years back. W.

**Mr. J. Simpson.**—The Société Nationale d'Acclimatation de France has, we understand, conferred its medal of the first class (Medaille de Première Classe) upon Mr. J. Simpson, Wortley Hall Gardens, for his book entitled "The Wild Rabbit in a New Aspect," published not long since by Messrs. Blackwood and Sons, Edinburgh.

**The late Mr. Chas. Collins.**—A meeting of horticultural pressmen was held recently at the Horticultural Club, Hotel Windsor, to take steps to raise a fund for the widow and children of the late Mr. Chas. Collins, whose sudden death was recorded in THE GARDEN. Subscriptions may be sent to any of the horticultural papers.

**Gardeners' Royal Benevolent Institution.**—The following are the names of the successful candidates, with the number of votes for each, at the election held on Thursday, January 17: James Clarren, 2824; Thomas Thomas, 2735; Emma A. Ivery, 2500; Henry Fielder, 2261; Clara E. Brown, 2188; Robert Pettitt, 2024.

**Names of plants.**—John Bennett.—Orchids correctly named, but not the best forms.

*The Wild Garden: or, the Naturalization and Natural Grouping of British Exotic Plants, with a chapter on the Garden of British Wild Flowers. Fourth edition, with wood engravings from drawings by Alfred Parsons revised and enlarged. Pemy 2vo, linen cloth. Price 12s.; well bound in half morocco, 18s. Through all booksellers.*

No. 1210. SATURDAY, January 26, 1885. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHIDS.

## PHALÆNOPSIS IN WINTER.

THE blooms of the Moth Orchid are always pleasing, more especially at the present time, when flowers are exceedingly scarce. These plants do not receive so much attention as they deserve, no doubt in consequence of the large amount of heat and moisture required to grow them to perfection. Occasionally one may notice a few kinds of Phalænopsis doing well under quite cool treatment, but I question if they continue in good health for many years. From personal experience I have known these plants thrive admirably during the summer months when given comparatively cool treatment, but in the winter the lower temperature and dryness of the atmosphere generally do much damage to the beautiful leaves and roots, and when so affected the plants take a long time to recover. Phalænopsis succeed best when grown in a house set apart for their cultivation, as in a state of Nature they grow where the atmosphere is nearly always saturated with moisture, and consequently they require similar conditions as far as possible in our houses. These plants mostly commence to make fresh growths in the early spring and continue growing until the autumn, when the resting period begins. During this season, however, they must be kept nice and moist, the Sphagnum being constantly kept in a fresh growing state. Care should be taken not to pour the water directly upon the leaves, only applying it to the Moss, and when fully open the flowers should not be sprinkled with water from the syringe, for this causes them to become spotted and soon decay. During the present season the thermometer should not fall much lower than about 70° in the daytime and 5° less in the night, but when the plants commence growing in March or April the temperature should gradually rise to between 75° and 80°, and during the night never fall below 70°. Much benefit may be derived by occasionally sprinkling upon the floor whilst the plants are in growth some soot and salt and also a little manure at intervals. Phalænopsis succeed well in either baskets, cylinders, or upon blocks, and require no other materials around their roots than good living Sphagnum Moss. These should be suspended from the roof or placed in a light position, and during the summer the plants must be protected from the sun's rays. One of the most beautiful kinds now in bloom is

*P. Schilleriana*, a charming species even when not in bloom, for its lovely variegated foliage contrasts well with the bright shining leaves of other sorts. This plant has been known to European gardens since 1860, having been introduced from the Philippine Islands the year previously. The leaves are large, deep green, and mottled with silvery grey, and it produces a long branching peduncle of many flowers. These individually are 3 inches and sometimes more in diameter, white, suffused with delicate rosy purple, and spotted minutely with red at the base of the lip. Amongst others in bloom at the present time is

*P. Aphrodite*, or, as it is better known in our gardens, *P. amabilis*, a grand variety, with deep green foliage above and purplish beneath. This also has fine large flowers, pure white, the side

lobes beautifully pencilled with purple and stained with yellow in the throat.

*P. Leucorrhoda* is also a beautiful kind and a supposed natural hybrid between the two previously mentioned species. Sometimes the foliage is quite green, and often slightly marbled as in *P. Schilleriana*; the sepals and petals are white, more or less suffused with rose, and the lip is intermediate in shape between those of the two supposed parents.

*P. Intermedia Portei*, also noticed in flower, is a rare and beautiful variety of the typical form. It has medium-sized, bright green leaves and flowers of exquisite form and colour; the sepals and petals are white, flushed with purple at the base; whilst the front lobe of the lip is a deep violet-purple, the side lobes light yellow, dotted with red.

*P. F. L. Ames* is also a very rare and distinct kind, being one of a few garden hybrids in this genus. It was raised by Mr. Seden in Messrs. Veitch's nursery between *P. amabilis* and *P. intermedia*. In this kind the sepals and petals are narrower, white, shaded with rose; the front lobe reddish purple with a yellow disc.

These by themselves make a very beautiful display during the dull months of winter, and well repay for any little extra attention bestowed upon them. WM. HUGH GOWER.

**Watering Calanthes.**—It is surprising what a small quantity of water the Veitchi and vestita varieties of *Calanthe* require while developing their flower spikes. Since the middle of November my plants have been watered only once. Many of the pseudo-bulbs are carrying spikes from 3 feet to 4 feet long—a proof that the treatment they receive is satisfactory. It may not be generally known that an excess of moisture at the root changes the colour of the flowers from that rich rose so pleasing to quite a pale pink. When these *Calanthes* are grown in a compost light in texture they may require, perhaps, more water, but I do not think soil of this character is the right kind for this useful winter-flowering Orchid. I employ a compost almost entirely composed of strong loam in a half-decayed condition, with sufficient charcoal to keep it porous and cow manure to sustain the growth.—E. M.

**Cymbidium Traceyanum.**—It is about four years since this beautiful plant first appeared with Mr. Tracey, of Twickenham, amongst an importation of *C. Lowianum*. I recently noticed in the collection of Mr. J. Prewett, of Hammersmith, a nice piece carrying a spike of several flowers. I suppose this has also been imported with a consignment of *C. Lowianum*, from which it is not distinguishable when not in bloom. It is closely allied to *C. giganteum* and *C. grandiflorum*, and it is to be hoped that some of our collectors may be fortunate enough to come across it in flower in its native country and send it home in quantity, for it is certainly a grand addition to this fine family of Orchids.—G.

**Lælia harpophylla.**—This is a handsome Orchid when well grown, and one which, on account of the bright and lively colour of its flowers, should be represented in all collections. It is somewhat early for this species to be in bloom, but I have noticed that several Orchids are flowering earlier than usual this season, perhaps owing to the very mild autumn and early winter. The flowers are produced from the top of the stem-like pseudo-bulbs in racemes of five or six. Each flower measures 3 inches across and is bright orange-red, with the exception of a whitish margin to the lip. This species is easily grown and very free-flowering; it is, moreover, a very accommodating plant as to temperature. It will thrive with the *Odontoglossums*, but the best position is in the intermediate or Cattleya house. Newly-imported plants certainly grow away with greater freedom in this warmer temperature. These when received should be carefully cleaned and suspended head downwards from the roof. When the pseudo-bulbs plump up and show signs of breaking into growth the plants should be placed in pots nearly

filled with clean crocks. A small stake must be placed in the centre of each, and one of the strongest pseudo-bulbs tied firmly to this; the others should be looped up neatly, using matting twisted up tightly. The plants will then look much tidier than if left loose, and as they cannot rock will also thrive better. A very thin surfacing of compost will suffice for the first year, and water must be sparingly applied until the roots have obtained a good hold of this. The syringe must, however, be freely plied between the pots, and on bright mornings in summer the plants may be lightly dewed overhead with tepid water. When the growth is complete the plants may with advantage be removed to a light sunny position in a cooler house and kept rather drier at the roots until the flower-sheaths begin to show, when they may be returned to the Cattleya house.—H. R.

## PROPAGATING ORCHIDS.

ORCHIDS of many popular and beautiful kinds are now so cheap and easily obtained that, from an economic point of view, artificial propagation of these is not worth the trouble involved. Still, sometimes one has a variety that it is desirable to propagate, and in such cases, slow though the process may be, the time and trouble will be well spent in the endeavour to increase the stock. Amateurs and others unacquainted with the culture of Orchids ought to gain some experience in growing them before attempting their propagation. The reason of this is obvious. Many plants that to the casual observer seem healthy and strong may, to a practical eye, be found wanting in some particular. The roots may not have a firm hold of their adopted home in pot or basket, or the leading growths or pseudo-bulbs may not be so robust as those preceding them. A careful cultivator will note these and other signs before commencing any operation that may possibly have a further weakening effect upon the plants. Given strong healthy plants, however, and skilful treatment, these experiments are very interesting. Some Orchids are quite easily propagated, as, for instance, the group of *Dendrobies* with long stem-like or terete pseudo-bulbs, as *D. mobile* or *D. Pierardi*. These frequently produce young plants upon the end of the pseudo-bulbs, or they may be induced to do so by cutting these off after flowering and laying them in boxes or pans of Sphagnum Moss kept constantly moist. If this is done in spring nice little plants are produced by autumn, and half-a-dozen of these placed in a 6-inch pot will soon make shapely specimens. Strong pseudo-bulbs of *Calanthe Veitchi* or *C. vestita* may be cut in four vertically, and with careful treatment each quarter will produce a new growth. This must not, however, be undertaken unless a brisk bottom heat is at command, on which to start the pseudo-bulbs after being placed in small pots of Moss. When new growth is well advanced and the young roots can be seen, the pieces may be pulled gently apart and potted separately, to be afterwards grown on in the usual way. *Thunias* are easily propagated by cutting the old pseudo-bulbs into lengths of about 6 inches, and inserting five or six of these around the edge of a 4½-inch pot. The best time to do this is as soon as the growths have attained their full size. A mixture of peat, chopped Sphagnum, and finely broken crocks is the best compost, and the pots should be well drained and kept regularly moist in a warm corner of the East India house. If carefully treated each cutting will break into growth at the base, and they should be left in the pots until these are full of roots. If the growth by this time is not quite finished, the plants may be carefully repotted into 6-inch pots, but if this is complete, they must be gradually

dried off and left until the following spring. Pseudo-bulbous Orchids of the Cattleya and Odontoglossum types do not in most cases lend themselves so readily to propagation. The mode usually practised is to cut through the rhizome with a view to obtaining back breaks, the lead being then removed and set growing on its own account. This plan does not, of course, allow of so rapid an increase as those described above. In the case of Cattleyas it is safer to notch a little more than half way through the rhizome at first, then when roots are emitted from the portions to be divided, cut right through, leaving them undisturbed until the pseudo-bulbs are formed, and dividing at next potting time. With some Orchids, however, this caution is unnecessary, *Lycaste Skinneri*, *Oncidium flexuosum*, *Burlingtonia decora*, and many others being easily propagated simply by dividing the plants as described and watering carefully until new roots are formed. *Cypripediums*, too, are easily increased by division of the plants. Each growth can be separately potted if desired, and will make a plant, although it is generally advisable to leave three or four together. *Vandas* and other Orchids of a similar habit frequently produce side breaks that may be taken off with a few roots attached and placed in small pots of Sphagnum and charcoal. These soon grow into neat little specimens in a suitable temperature, and no harm can accrue to the parent plants by their removal. It must not be forgotten that in all these operations a slight check is given to the plants, and this must be counteracted by extra attention until they recover. A kind of convalescent treatment is necessary, a little more heat than usual and a rather closer atmosphere being very recuperative.

H. R.

***Cypripedium Roezli*.**—I recently saw an exceedingly finely coloured variety of this old favourite. It belongs to the *Selenipedium* section and much resembles *C. longifolium*, of which species it is considered a variety by some authorities. The flowers are similar in shape to those of *C. longifolium*, having a large greenish lip and long pointed petals. In *C. Roezli*, however, they are of a much deeper colour than is ever seen in *C. longifolium*. This is almost a perpetual blooming species, with a long, erect spike which seldom has more than one flower open at a time. It was discovered about fifty years ago on the Andes of Ecuador, growing at about 4000 feet elevation, and first flowered in this country in 1874 with Messrs. Veitch and Sons, of Chelsea.—W.

#### SHORT NOTES.—ORCHIDS.

***Masdevallia Courtauldiana*.**—This was raised by Mr. Norman Cookson, of Wylam-on-Tyne, between *M. rosea* and *M. Shuttleworthii*. The scape is slender, rather longer than the leaves, and one-flowered, the flowers being of a uniform shade of light rose. It is now close on six years since this fine variety first bloomed. W.

***Cymbidium Winnianum*.**—Only two hybrids have appeared in this genus, *C. Winnianum* being one. It is certainly very distinct and a fine acquisition, being a cross between *C. giganteum* and *C. eburneum*. The plant appears to be very vigorous, and the fine ivory white blossoms, which are spotted with crimson at the base and borne on long arching spikes, last a considerable time in perfection.—W.

***Epidendrum polybulbon*.**—This is a native of Mexico, and, I believe, has also been found in the West Indies. It has been known for a considerable number of years, but was not seen in a living state in this country for a long time after its discovery. The blooms are each about an inch or more across; the sepals and petals, nearly equal in size, are yellowish green; the lip pure white, striped in the middle with yellow.—G.

***Cypripedium Mrs. F. Hardy*.**—This fine hybrid, recently shown at the Drill Hall, Westminster,

by Mr. Hardy, is the result of crossing *C. bellatulum* with *C. superbiens*. The flower is of pleasing appearance, with slightly drooping petals, and borne upon an erect stem from 9 inches to a foot in height. All the segments are pure white and heavily spotted, with the exception of the lip, which is shaded with brownish rose in front.—W.

***Dendrobium nobile elegans*.**—Under this name I have received some blooms from Mr. Cypher, the Queen's Road Nurseries, Cheltenham. In this form the flowers are of extra substance and also of fine size, measuring nearly 4 inches across the petals. The sepals and petals are broad, heavily tipped with rich rosy purple, lighter at the base; the lip is pale yellow, and has an exceedingly deep maroon blotch at the base, the tip being rosy purple.—W.

## TREES AND SHRUBS.

### NATIVE EVERGREENS.

WHEN after a very hard winter we see the evergreen trees of the garden in mourning, and perhaps many of them dead, as happens to Laurels, Laurustinuses, and often even the Bay, it is a good time to consider the hardiness and other good qualities of our British evergreens and the many forms raised from them. If we are fortunate enough to have old Yew trees near us, we do not find that a hard winter makes much difference to them, even winters that brown the evergreen Oak. We have collected within the past 200 years evergreen trees from all parts of the northern world, but it is doubtful if any of them are better than the common Yew, which when old is often picturesque, and which lives for over a thousand years. Of no other evergreen introduced to Britain can anything of the kind be said. Of this great tree we have many varieties, but none of them quite so good as the wild kind when old. In the garden little thought is given to it and it is crowded among shrubs, or in graveyards where the roots are cut by digging, so that one seldom sees it in its true character when old, which is very beautiful. The Golden Yew is a form of it, and there are other slight variegations which are interesting from a merely garden point of view. The Irish Yew is a well-known form, and its prim shape is too much seen. Other seedling variations of the common Yew are better than that kind.

After the ever-precious Yew, the best of our evergreen shrubs is the common Holly, which in no country attains the beauty it does in our own; certainly no evergreen brought over the sea is so valuable not only in its native form, often attaining 40 feet even on the hills, but in the almost innumerable varieties raised from it, many of them being the best of all variegated shrubs in their silver and gold variegation; in fruit, too, it is the most beautiful of all evergreens. Not merely as a garden tree is it precious, but as a most delightful shelter around fields for stock in paddocks and places which want shelter. A big wreath of old Holly unclipped on the cold sides of fields is the best protection, and a grove of Holly north of any place we want to shelter is the best thing we can plant; the only thing we have to fear being the rabbits, which when numerous make Holly difficult to establish by harking the newly-planted trees, and in hard winters even barking and killing many old trees. As to the garden, we may make beautiful evergreen gardens of the forms of Holly alone.

Notwithstanding the many conifers brought from other countries within the past few generations, as regards beauty, it is very doubtful if more than one or two equal our native Fir, which when old is so fine in its stem and head.

Few things in our country are more picturesque than old groups and groves of the Scotch Fir; few indeed of the conifers we treasure from other countries will ever give us anything so good as the ruddy stems and frost-proof crests of this northern and British tree.

Again, the best of evergreen climbers are our native Ivy, and the many beautiful forms allied to it or that have arisen from it. This in our woods arranges its own beautiful effects, but in gardens it might be made more delightful use of, and no other evergreen climber comes near it in value. The form most commonly used in Britain—the Irish Ivy—is by no means so graceful as some others, and there are a great number of delightful forms varying in form and even in colour. These for edging banks, screens, covering old trees, and forming summer-houses might be made far more use of. In many northern countries our Ivy will not live in the open air, and it is so happy with us, that we rarely take advantage of our privileges in such a possession in making both shelters, wreaths, and screens, and many beautiful things of it that would need little care. It requires care in trimming on our houses and on cottage roofs; but there are many pretty things to make of it away from buildings, and among them Ivy-clad and Ivy-covered wigwags, summer-houses, and covered ways, the Ivy supported on a strong open frame-work, and trained over sticks till it took hold.

The Box tree, which is a true native in certain dry hills in the south of England, is so crowded in gardens, that one seldom sees its beauty as one may on the hills full in the sun, and the branches take a charming plummy toss. To wander among natural groves of Box is a great pleasure, and there is no reason why we should not plant it in groups or colonies by itself full in the sun, so that one might enjoy the same charm of form that it shows wild on the hills. In some heavy soils in England it does not grow, but there are many of our soils that suit it perfectly. A bower of one of the handsome-leaved Ivies in a grove of Box would be charming, and its charms would last long.

Also among our native evergreens is the common Juniper, a scrubby thing in some places, but on heaths in Surrey, and favoured heaths elsewhere, often growing over 20 feet high and very picturesque, especially where mingled with Holly. There is an upright form, called the Irish Juniper, in gardens.

The Arbutus, which borders nearly all the streams in Greece, ventures into Ireland, and is abundant there in certain parts in the south. This beautiful shrub, though tender in midland counties, is very precious for the seashore and mild districts not only as an evergreen, but for the beauty of its flowers and fruit. Still, it is the one British evergreen which has to be planted with discrimination in places where the winters are severe in inland districts.

***Osmanthus ilicifolius*.**—Apart from its value as an evergreen shrub so well set forth on p. 17, this *Osmanthus* is decidedly pretty when in bloom, or rather when flowering as profusely as it did during the autumn of 1893, for the blooms are small, and consequently when produced in limited numbers they are not particularly attractive. The flowers are pure white and produced in clusters from the axils of the leaves. These clusters of blossoms extend for some distance along the shoots, so that when every twig is crowded with them they are very noticeable. Like those of a nearly allied plant, *Olea fragrans*, the blossoms of the *Osmanthus* are very pleasantly scented; indeed, in many features they bear a great resemblance to this *Olea*, but are much whiter. I never before saw the different kinds of

Osmanthus flower with anything like the freedom that they did in 1893, the result no doubt of the almost tropical summer. Last year, on the other hand, very few flowers made their appearance. Besides the forms mentioned in the above quoted article there is the variety *myrtifolius*, a plain dark green, unarmoured leaf, which undoubtedly originated as a sport from the typical kind, as it will occasionally show signs of reversion. This variety forms a neat, freely-branched little bush, not unlike a *Phillyrea*. A second form, *rotundifolius*, has rounder leaves, but the plant does not seem to grow so well as *myrtifolius*. Notwithstanding the great resemblance that some forms of this *Osmanthus* bear to a Holly, there is really no affinity between them, the genus *Osmanthus* being allied to the Olives. Such being the case, they were at one time often grafted on the Privet, and in this way were rarely satisfactory, but since the crusade has set in against useless grafting it has not been so much followed. There is really no reason why grafting should be employed for the propagation of the *Osmanthus*, as cuttings strike root readily enough. The best time to take them is at the end of the summer, when if kept in a frame they will be well rooted by the spring.—T.

EURYA LATIFOLIA VARIEGATA.

THE shrub so long known in gardens under the above name is, according to Sir Joseph Hooker, not a *Eurya* at all, its correct name being *Cleyera Fortunei*. Though cultivated in this country for upwards of thirty years, it has not flowered till recently, and its blooms were almost unknown till flowering examples of it were exhibited at the Chiswick conference on trees and shrubs held last autumn. The specimens shown were contributed by Lieut.-Colonel Tremayne, Carclew, Cornwall. This afforded the first opportunity of examining the flowers, with the result that this well known shrub has been proved to be a *Cleyera*, to which genus it was always considered to be nearly related. Of course, in the favoured western climate it is hardy, but in many districts of England it requires to be treated as a greenhouse shrub, and even then it is a very useful plant in many ways. In the matter of foliage this *Eurya* bears a certain amount of resemblance to a *Camellia*, but the leaves are longer in proportion to their length and not quite so thick in texture as those of a *Camellia*. The variegation of the *Eurya* does not consist of any regular markings, for the leaves when young present an almost indescribable blending of white, yellow, pink and green, but when mature a good deal of the pink disappears. Good examples are nearly as brightly coloured as some of the *Crotons*, and besides its ornamental foliage, the merits of this *Eurya* are still further enhanced by the fact that, being almost hardy, it may be kept in any structure from which frost is just excluded. In draughty corridors and such like places it may be employed without injury, the leathery texture of its leaves readily admitting of the removal of the dust which in such places quickly accumulates on the foliage. It is not at all a difficult plant to strike from cuttings, though at the same time it does not root so readily as many other subjects. The best cuttings are furnished by plants that have been wintered under glass, as they root more readily than the shoots taken from bushes in the open ground. The weaker side shoots should be chosen for the purpose rather than the stouter terminal ones. They should be taken when in a half-ripened condition, which will be as a rule about midsummer or thereabouts. A convenient length is about 4 inches, and if cut off to a joint and the bottom leaf removed, they may be dibbled firmly into well-drained pots of sandy soil. Then if kept in a close propagating case in a temperature rather higher than that in which they have grown, these cuttings will strike in two or three months, when they must be potted off. One caution to particularly observe is that the cuttings are not allowed to flag previous to insertion, as if this is done, many fail to recover.

It was an old, but now pretty well exploded, idea that cuttings of all kinds should be left some little time before insertion in order that the superabundant sap might drain away, and thus lessen the chances of decay; but it is now pretty well conceded that, except in the case of succulents and a few other things, the quicker the cuttings can be put in the better for their chances of success. T.

**Sciadopitys verticillata.**—My experience with the Umbrella Pine of Japan is anything but pleasant. Fifteen years since two plants were purchased, each costing a guinea; they were carefully planted in the natural soil, which was inclined to be heavy, excepting that a quantity of old garden soil was added when the garden was re-formed. No progress was made by the trees for several years, when they were removed to another part of the garden and planted wholly in peat, decayed leaves, and sand. An improvement was soon manifest in the growth and colour of the leaves, but it proved only short-lived; the plants very quickly changed to the objectionable hue they had assumed prior to removal. In spite of repeated watering when the weather was dry the plants got gradually less until they died five years since. With the exception of the first and second year after planting, the second time the plants never made any progress at all.—E. M.

**The Tulip Tree in Yorkshire.**—Referring to the note of your correspondent at p. 31, January 12, I can answer in the affirmative as regards *Liriodendron tulipiferum* succeeding, as far as growth goes, in the W. R. Yorks. About ten years since I planted a small tree at Holden Clough, and it is now a shapely tree of 12 feet to 15 feet high. Of course, I do not expect it to bloom, as in much more favoured climates than that of West Yorks it does not flower until it is a full grown, one may say aged, tree, but its foliage is so distinct and peculiar, that without bloom it is well worth growing. It is no doubt difficult to establish, but once thoroughly established it is of fairly rapid growth. Its enemy is not winter cold, but the early frosts of autumn which damage the young growths. Not so much, however, as in the case of the other tree mentioned by your correspondent, *Catalpa syriacifolia*; this can do no good, that is, cannot flower, from the above cause—want of ripening of the wood in autumn. I have had seedling plants of *Paulownia imperialis* a yard high which have been in their sappy condition killed off, like *Asparagus* shoots, by the early frosts. Neither very early nor very late growths answer in the W. Yorks climate, where, by the way, *Polygala Chamæbuxus*, from Geneva, has been flowering for the first time during the recent severe weather.—R. MILNE-REDHEAD, Holden Clough, Clitheroe.

THE DEODAR CEDAR.

If there is a conifer that in the last fifty years has been planted more largely than any other it is probably the Deodar Cedar, and planters have not, as a rule, had reason to regret the selection. This has not been the case with many others. Some, as *Sequoias* and *Araucarias*, have, as they grew into trees of considerable size, proved totally unsuitable for the sites chosen for them; others, as *Cryptomeria japonica*, go on satisfactorily until the leader gets into the wind line, when they are invariably crippled, whilst yet others are affected by certain soils, growth is ragged, and the tree, as a specimen, unsightly. I hardly think that any of these objections would apply to the Deodar. There are very few positions for which it is not suitable; its leader is not, as a rule, injured, and it is also not very particular in the matter of soil—at least it is to be found doing well under very diverse circumstances. One thing, however, I have specially noted, that difference of soil will materially alter the manner of growth. Sometimes the tree runs up quickly to a very considerable height with but a slender stem, whilst in other cases the trunk develops quickly at the

expense of rapidity of upright growth. It is too early to express a decided opinion as to the dimensions likely to be attained by this Cedar. It was introduced so lately as 1822, and consequently no comparison can as yet be drawn between it and the Lebanon Cedar, which has been in the country over 200 years, but I fancy on some soils the latter tree will have to give way to the Himalayan Cedar. I say on some soils, because doubtless to the difference in this respect is to be attributed the corresponding difference in the habit of growth of the Lebanon Cedar in two separate places, perhaps not so widely apart, to be noted in the nature of branch development and increased density of foliage. In those places where the latter characteristics are answerable for the early mutilation of the tree by gales and heavy snowstorms there should be no hesitation in substituting the Deodar when any Cedars are planted; its finer growth and more drooping habit are safeguards against the breaking down of branches. An inspection of some score or more trees that were planted here between 1850 and 1860 in different parts of the pleasure grounds shows that in every case they are doing remarkably well, varying a little in their manner of growth, but all clean, healthy, well-balanced trees. On small lawns and in any positions where it is not advisable a tree should go higher than some 30 feet, the glaucous variety of the Atlas Cedar, a beautiful tree that makes a small, but very shapely specimen, may be substituted for the Deodar. E. BURRELL.

Claremont.

THE ENGLISH YEW.

It is a pity there are not authentic records as to the age of some of the remarkable specimens of English Yew that are to be found occasionally in our churchyards or in some of the "coombes" of our down land. We may hazard a guess, and possibly think ourselves near the mark as to the age of the churchyard patriarchs, associating their planting with the earliest record of a church in the same spot, but it has often seemed feasible that the largest Yews reach further back than such records, and that they were contemporary in their infancy with still earlier buildings of which no trace remains. This inference is forced on one when there is an opportunity of measuring trees of whose age we can speak positively, contrasting the progress they have made in the time with the enormous girth of some of the largest known specimens, and also comparing the young Yews with other species of trees. In the planting operations associated with the laying out of the grounds here Yews were somewhat freely used, and are to be found in circular groups, in cross avenues and as isolated specimens. This planting was carried out in 1770, giving them an age of 125 years, and a measurement of a few trees taken here and there shows them to run from 25 feet to 30 feet in height, with a diameter of bole from 24 inches to 30 inches (the latter exceptional) at 3 feet from the ground. Naturally, where somewhat crowded either by their fellows or by other trees they are lacking in symmetry, but isolated specimens are very shapely trees, throwing their branches far and wide. As against the measurements of the Yews I should like to chronicle one or two made of other trees that were planted at the same time to show the difference in the rate of growth. Many of the Lebanon Cedars are 70 feet high and girth from 15 feet to 18 feet, verifying the contention of the late Mr. Marnock that, given a congenial soil, this tree was of fairly rapid instead of slow growth. The majority of the Silver Firs would girth about the same as the Cedars, but are nearly 100 feet high. These are going to the bad rapidly, forming in their decay a striking contrast to the luxuriance of the Yews of similar age. The knowledge gained as to the Yew's rate of growth furnishes an ample reason as to why large specimens are so seldom found in private pleasure grounds. There are few of these that have remained unaltered for centuries.

E. BURRELL.

## CHRYSANTHEMUMS.

### CHRYSANTHEMUMS FOR MARKET.

With flowers, as with other things, time and fashion work wondrous changes. Many things which held a foremost position with the older generation of gardeners are now relegated to obscurity. This cannot, however, be said of the Chrysanthemum, for, looking back through a period of thirty years, one sees it advancing slowly at first, and then by leaps and bounds to its present high state of popularity. It is doubtful whether the Chrysanthemum would have become so popular and been so largely grown for market had raisers of new kinds never had the Japanese varieties to deal with. These are so showy, generally so free of growth, such a large amount of bloom can be taken from a comparatively small area, while they lend themselves much better to the rough-and-ready cultural methods of the grower for profit than do the incurred kinds. By their means it has been easy to produce that enormous amount of bloom in an inexpensive manner that fills up the London and large provincial markets for several months in the year. The Chrysanthemum season may be said to commence about the middle of September and last almost until February. Instead of Chrysanthemums being, as was the case but a few years ago, very expensive at the festive season, they can be bought almost as cheaply then as at other times of the year. Not much more than ten years ago a house 100 feet long filled with Chrysanthemum bloom in midwinter was thought something out of the common, but to such an extent are the late-flowering varieties cultivated now, that one may find in our London market gardens as much bloom at Christmas as would have been produced twenty years ago in all the market gardens about the metropolis. It is not uncommon during the season to see a whole vanload of Chrysanthemums sent into Covent Garden by one market grower. The

### OUTDOOR CULTURE

of this flower has of late been much developed. Not only are the early-blooming kinds very largely grown, but the later blooming hardy varieties are produced in much greater quantities than formerly. These are, of course, much influenced by the weather that may happen to prevail at their blooming period. Sometimes a hard frost will kill or much injure them, but in a general way they now form an important feature in the London flower markets in late autumn. The past season was unusually favourable to this flower. The rainy summer favoured a luxuriant growth, and there was not frost enough later on to check flower expansion. It has thus been possible to form a correct idea of the extent to which these hardy Chrysanthemums are grown for profit in the neighbourhood of London. It would almost seem that as much ground is being given to them as to the Wallflower, for this year the blooms have been brought to the London markets in the same manner as is practised with that fragrant flower. Wagon-loads of vegetables topped up with these hardy Chrysanthemums have been frequently seen this season in Covent Garden. Probably no Chrysanthemum has been so largely grown as Madame Desgrange, but there are signs that its reign of popularity is on the wane. Complaints are made of its want of purity. Florists cannot employ it where flowers absolutely pure are indispensable, and they say "it does not go" with white flowers generally. When grown

in pots and accorded high culture, the flowers come pure enough, but this method of culture does not pay much, and planted in the open it is much influenced by the weather, the yellow tinge being more or less pronounced, according as the season has been favourable or otherwise to the growth of the plants and expansion of the blooms. Sometimes the foliage is affected by a kind of disease which partially cripples the plants and spoils the purity of the flowers. The newer Lady Fitzwygram seems likely to rival Madame Desgrange, but whether it will prove sufficiently reliable in the open air and will suit market requirements can only be determined by two or three seasons' trial. If raisers can give us a variety as good as Elaine of a robust habit and early enough to bloom in the open air in September, they will earn the thanks of growers for profit. Ryeoort Glory and Comtesse de Careil are certainly very useful additions to this section of a large family, and are sure to be largely grown. Except when the plants are to be sold, I feel sure that it will not pay to grow any of these early blooming kinds in pots. The little increase in quality will not compensate for the extra expense involved by pot culture. The culture must be simple, sheltering the stools in frames in winter, dividing and planting out in good ground towards April. Some who grow Mme. Desgrange largely protect with canvas during the flowering time, and no doubt this pays taking one year with another. In some years a sharp frost occurs in the latter portion of September, and the man is happy who has then half an acre of this Chrysanthemum and its varieties. When Dahlias and other tender flowers are cut off and unprotected Chrysanthemums are injured, the price of blooms in good condition naturally goes up. It is hardly correct to call Elaine, W. Holmes, and Source d'Or midseason varieties. They are really second earlies, coming in several weeks before the Chrysanthemum season fairly commences. These three kinds probably pay as well as the latest ones, and certainly much better than those that are marketed from the beginning of November up to Christmas. Good blooms of Elaine and W. Holmes will often make more in mid-October than those that are retarded up to the close of the year. Fairly good flowers of the latter realised 4d. each last season, and a Chrysanthemum must be very good indeed to make so much at the festive time. This comparatively high figure is only to be obtained from the earliest blooms, and can hardly be secured from lifted plants. The great bulk of these second early varieties brought into Covent Garden is very poor, being produced by plants grown on the rough-and-ready method. If grown in pots they can be put under cover without sustaining a check, can get the full sun and being well fed will come on rapidly. These three varieties can be had all through November by means of late stopping and keeping them in the open as long as possible. I do not think there is much advantage in treating Elaine in this way, as we have plenty of good whites that can easily be had early in November, but the mixture of crimson and gold in W. Holmes renders it such a favourite, that one is justified in prolonging its season as long as possible. Among later varieties that bloom from the beginning of November till the middle of January, Avalanche, Sunflower, Gloire du Rocher, Stanstead White, Edwin Molyneux and Felix Cassagneau are among the best and are all easily grown. Callington is still one of the best high-coloured kinds, but it does not make any great quantity of fibrous roots when planted out and is apt to suffer when lifted.

Grown in pots it is very satisfactory and will yield as much bloom from a given space as almost any Chrysanthemum. Edwin Molyneux is, however, much stronger in growth and the flowers have none of the much-admired old gold tint in them. It is not necessary to grow both, and for November and the early part of December I should prefer E. Molyneux. A. Dufour is a good kind for cutting, bearing an abundance of rosy purple flowers, the habit being all that could be desired. Mlle. Thérèse Rey, Mrs. E. G. Hill and H. Shoemith will be grand for market work if they will adapt themselves to the market growers' cultural methods; if not they will, however fine, be valueless for profitable culture. Numberless fine varieties are shut out from our markets through not being sufficiently free-flowering or robust in habit. This remark applies especially to that period when the London markets are glutted with Chrysanthemums. The prices then range so low, that only the simplest culture applied to the most prolific kinds will yield any profit. The amount of glass now occupied by this flower is enormous, the rule being Strawberries, Tomatoes, and then Chrysanthemums.

Propagation from cuttings is rarely resorted to; the old stools are pulled to pieces, dibbled into light soil in frames, kept hard and sturdy, and set out in beds at the latter end of April or early in May. A large proportion of the blooms thus produced are of very indifferent quality, but they meet a want, and the cultural expenses are, of course, very small as compared with those involved by pot culture. A few years ago all Chrysanthemums that came in after the first week in December were classed among the late bloomers, but the flowering time has been extended so far into the new year, that a variety which cannot easily be had in good condition at Christmas must now go with midseason kinds. A very prominent place among

### LATE VARIETIES

has this season been taken by W. H. Lincoln. This is undoubtedly the best of the late blooming yellows. The flowers are fine in form, rich in colour, of good substance, and the growth is sturdy and dwarf. It appears also to be but little susceptible to mildew, a very important point in the case of market Chrysanthemums, which, owing to the way the plants are crowded when housed, are apt to suffer much from this disease. There is no difficulty in having good blooms of this in the middle of January. W. H. Lincoln has had a warm welcome from the florists, which of course means much, but another year's trial will be necessary to fully determine its merits. Of the well-known Golden Gem it would be difficult to say too much. It is in every respect reliable, and can be had in fine condition from mid-December till the end of January. It is indeed a rare January Chrysanthemum, and I think it will hold its own for some time to come. Few Chrysanthemums will yield so much for a little trouble as Golden Gem. I have this season taken a lot of nice flowers from plants that have been three years in the same pots. They were cut back hard, turned out of doors in April, and were occasionally watered with liquid manure. It is not many Chrysanthemums that would give good results under such treatment. Golden Gem varies wonderfully in colour, according to the season at which the blooms open. Those that commence to expand early in December develop a lovely shade of apricot, which is most pronounced when a certain amount of disbudding is practised. The later plants that come into flower about the middle of the month show little or nothing of this coloration, the flowers

being of a clear yellow. *Boule de Neige* is, I consider, one of the most useful *Chrysanthemums* we have. It gives less trouble than any variety I have ever grown. It is dwarf, but vigorous, requires no staking, no stopping and is mildew-proof. Housed in the first week in October, it comes in nicely from mid-December to the new year, but it is of no use for January cutting. Its place can then be taken by *Lady Lawrence*, acknowledged as the finest late white, but, unfortunately, very subject to mildew. *L. Canning* is a worthy

gives just the variety of colour so much needed, for without it one is reduced to a dead level of yellow and white at the close of the year. *E. Molyneux* can also be had tolerably late, but is not so reliable as the foregoing. For very late bloom, say from the second week in January up to February, pot culture is decidedly best and I am inclined to think pays, for at that time there is a marked rise in price. It is difficult to keep the foliage in good condition after December on lifted plants, but it is easy to do so with well-rooted pot plants, and if the leaves

lected. To secure the crown bud at a suitable time for taking, the plants must be stopped the last week in March or the first week in April. As soon as the plants break from the stopping, a single shoot is taken up and grown on in the ordinary way, the crown bud showing the first week in August or thereabouts.—A. Y.

JAPANESE CHRYSANTHEMUM  
VAUCANSON.

A VERY few years ago it was the custom of the *Chrysanthemum*-growing fraternity of Toulouse to refer to that city as *le berceau du Chrysanthème*. For a period extending over sixty years the amateur and professional growers there had been indefatigable in their efforts to improve the flower by their seeding and selection of the numerous varieties that they obtained, but during the past seven or eight years raisers have sprung up in other parts of France who bid fair to eclipse even the most successful of the southern growers. Some little suspicion of coming events seems to have been present in the mind of a writer in the "Annales de la Société d'Horticulture de la Haute Garonne" (vol. xxxv., 1888), where he concludes a report on the society's work by referring to the extension of *Chrysanthemum* culture, and advises the amateurs and nurserymen of Toulouse to double their care and their efforts if they wish to maintain their position at the head of the *Chrysanthemum* world.

Whether this friendly counsel has been laid to heart by the growers of Toulouse it is difficult to say, but it is beyond doubt that Grenoble has in recent times acquired a reputation for new seedling *Chrysanthemums* the like of which Toulouse never possessed. The name of Ernest Calvat has become inseparable from the town of Grenoble, but even he is not alone in the work of seedling-raising in that town.

The variety selected for illustration in this week's issue, *Vaucanson*, is a Grenoble seedling raised by M. Ad. Testout, and was sent out by M. Hoste, of Lyons, in the spring of 1893. It was reported upon by M. Viviani Morel in the *Lyons Horticole* for January 15 of that year, but in what terms I cannot say, not being in possession of the number in question. At that time some little interest was being taken in the new section of hairy *Chrysanthemums*, and *Vaucanson* with others, such as *Chrysanthémiste Délaux*, *Enfants des Gaules*, *Mireille*, *Sautel 1893*, *Souvenir de l'Ami Coye*, and several others of less repute, were imported by Mr. Jones, of Lewisham, to meet the popular demand in this country. *Vaucanson* was at the time described as a seedling from Louis Boehmer, crossed with the American variety *Mrs. Andrew Carnegie*. The distributor pointed out that its colour, dark violet-amaranth, with a lilac reverse,

*Chrysanthemum Vaucanson.* From a photograph sent by Mr. H. J. Jones, Ryecroft Nursery, Lewisham.

companion to it, but I have not had enough experience with this to know if it can be grown on the planting-out method. *Princess Blanche* is a very late white that can be had in February. It is dwarf and free-flowering, and plants some 18 inches high will carry a score of nice pure white blooms. I should say that this would be good for marketing in pots at this time of year. Cullingfordli I have always found extremely useful at Christmas and the new year. I have generally grown my plants of this in pots for late bloom, stopping them at intervals through July and housing them about October 6. It

remain green the flowers will expand and stand well for several weeks. J. C. B.

**Chrysanthemum Bouquet de Dame.**—I was glad to see the note on this excellent early white *Chrysanthemum* by "E. M." It has a certain refinement about it when grown for large bloom—not to be met with in the majority of other white kinds, although these may be larger. For coming in before the majority of late October and early November varieties I grow a fair number both of *Bouquet de Dame* and *Mme. Louise Leroy*, both being excellent for the purpose. To obtain good flowers the crown bud must be se-

quite new in its class, and this is undoubtedly the fact. Under English treatment the flower is large, very hairy, as the illustration shows, having sharp pointed florets, forming a very globular, solid-looking bloom of the Japanese incurved type. The blooms which first came under my notice were those grown by Mr. Jones in the year of its introduction, when I paid him a visit as late in the season as November 27. I also saw it again in the Ryecroft Nursery on November 3 last year, and again at a meeting of the N.C.S. floral committee on the 21st of the same month. On

each occasion it seems to have been a characteristic bloom, for my notes of its description specially allude to the Japanese incurved form of the flower, the great length of floret, and the sharply pointed extremities.

To those who admire varieties of this peculiar section, *Vaucanson* is undoubtedly an acquisition and worthy of cultivation. If less chaste in appearance than *Enfant des deux Mondes*, it has not the feeble constitution of *Mrs. Alpheus Hardy* nor the dull, unattractive colour of *Louis Boehmer*. It is larger in size than either of these, more globular in build, and a more massive flower in every way. The chief aim of those growers who are now devoting themselves to the hairy varieties should be improvement in constitution, build and colour. When this is accomplished, hairy *Chrysanthemums* may become much more popular than they are now. Although it is too early in the year to give any estimate of the number of new hairy varieties that we shall receive from France or America this year, it may be useful to mention that one seedling grower informs me he will distribute seventeen varieties of his own raising.

In conclusion, it may be observed that *Vaucanson* is of a deeper and better colour in every respect than *Louis Boehmer*. It is a variety that offers no difficulties in the way of cultivation. Its season is the month of November, as will be seen from previous remarks, and it has the advantage of not being over-tall, about 4 feet being its height. To secure large blooms, crown buds should be taken in August, and the size of pots for the final shift should be 10 inches.

C. HARMAN-PAYNE.

#### CHRYSANTHEMUMS FOR THE NEW YEAR.

LATE-FLOWERING *Chrysanthemums* are so valuable for cutting, that I always grow a good number of them. It may be of service to some of your readers if the names of those now (January 4) in full bloom are given. Of large-flowering Japanese kinds, *W. H. Lincoln* is the best. This has been written of as an early-flowering kind, but by selecting the terminal buds and reducing them to from nine to twelve on a plant, good blooms can be had at this season, and the deep yellow or golden colour of the flowers makes them most effective. The habit, too, being naturally dwarf and the foliage also good, enhance its value, as the plants may be used for house decoration. Its one drawback is that it requires dis-budding, small flowers being neither shapely nor effective. Of the same colour is *Golden Gem*, a most valuable kind when well grown. It requires quite different treatment from the foregoing, as dis-budding entirely spoils it. It should be allowed to develop all its buds, then beautiful sprays of flower will be the result. I do not think that this kind is grown nearly so much as it deserves, probably because it has been found wanting in size even when dis-budding has been practised, and the colour, too, suffers under such treatment. *Chrysanthemums* vary greatly in their lasting powers when cut, but I find this variety quite one of the best stayers we have. *Boule de Neige* is also an excellent variety, and it should be treated precisely the same as *Golden Gem*. It is even more free-flowering than that variety, and both kinds being naturally late-flowering, no special treatment is needed to get them to bloom at this season. The flowers are pure white and remind me very forcibly of those of *Ethel*, which it greatly resembles, the difference being in size, *Boule de Neige* being small-flowered. All the above-mentioned kinds carry their foliage very well indeed. *L. Canning* is a pure white, large-flowered, reflexed Japanese. I have it in good form now on dis-budded plants. The only doubt I have about it is that it is not

free-flowering enough to make it very profitable. *Mrs. E. W. Clarke* is another large late kind, and belongs to the incurved Japanese class. In addition to its lateness it has the charm of being violet-scented, and its colour, amaranth, is rare at this season. *Pelican* is a very fine kind for late work, and its creamy-white much-curved florets make it a very attractive variety. The last on my list is *Christmas Eve*, or *Mrs. H. Cannell*: unfortunately, the same variety has been sent out under both names. When well grown it is magnificent. In size—I do not mean depth—(mere lumpiness of bloom I hate in a *Chrysanthemum*), in form, and in the purity of its whiteness it is unsurpassed. The great height of the plant is its one bad point. Like the three foregoing, it must be dis-budded to get it in good form; if not, it will show an "eye" that spoils its purity.

In addition to the above I have still very good blooms of *Lord Brooke*. This I have yet to prove for late work, its lateness this year having probably been due to late striking. There is, however, no mistake about its lasting powers, as blooms that were fully expanded some weeks ago still look quite fresh.

J. C. TALLACK.

**Striking *Chrysanthemums*.**—A trade grower recently remarked to me that it was a bad plan to propagate *Chrysanthemums* from plants that have been highly fed. The cuttings, he observed, might look stout and the growth of the plants afterwards appear strong and satisfactory, but in the end unripe wood, blind buds, and deformed blooms result. Far better is it, he observed, to increase the stock from plants grown under the non-stimulating treatment, even though they should be smaller and less taking in appearance to start with. In proof of the truth of his assertion I may mention that a batch of plants grown near here for the production of large blooms and raised from ordinary decorative stock produced flowers deeper and more solid, though somewhat smaller and less coarse than are generally seen. Moreover, the flowers lasted much longer in good condition.—J. C.

***Chrysanthemum Etoile de Lyon*.**—I was not aware until recently that this variety could be had in such good condition so late in the season. Only lately I saw in a small nursery in the midlands a good stock of it in really good condition. The plants had been grown on two in a 9-inch pot, stopped fairly late, and not subjected to any feeding. They were kept out in the open as late as possible, being, of course, protected from frost at night, and when brought indoors were placed in a cool house. The petals were not coarse, as is generally the case with large blooms of this variety, and the centres were nicely filled up, which can seldom be said of the various late whites. Those who need white flowers in January will do well to give *Etoile de Lyon*, grown on the above principle, a trial.—J. C.

***Chrysanthemum Miss Dorothea Shea*.**—"Grower," in his notes on "*Chrysanthemums at the Royal Aquarium*," mentions a bloom of this variety as being the best in the whole exhibition. It would be interesting to know the height of the plant the bloom was taken from. I have secured large flowers and of good colour of this variety, but the plants which produced them grew to the height of 9 feet, and I do not think I shall grow it again, as a plant which grows to this height before giving its best bloom is useless to me. The height given in catalogues is 5 feet, but the flower produced at this height, and which is from the first crown bud, is very poor. If the best flowers are only to be secured from terminals, then this and the height the plant will ultimately attain should be given. According to my experience, *Chrysanthemums* which grow tall before producing their best flowers are of little use.—A. YOUNG.

***Chrysanthemum Golden Wedding*.**—Anent my note of the above variety (p. 514, last volume), "A. Y." inquires (p. 9) whether the

failures to which I referred are not the result of over-feeding. For the majority I cannot say, but speaking of it in two instances which came under my notice, failure was certainly not due to "over-feeding," or, indeed, feeding at all, as we usually accept the term. In the one no chemical manures were applied at all, and in the other soot-water and top-dressings of soot were used periodically. Yet, notwithstanding, several plants in both instances perished, and to the growers of them the reason is by no means clear. The manner of their dying off is, however, quite compatible with over-feeding, and it is possible that over-watering may be at the root of the trouble. The demand for it has been large, and no doubt a large portion of the stock has been raised from "eyes" only. Such as these could not possibly possess the vigour of good root cuttings. When these latter are plentiful we shall no doubt see *Golden Wedding* in its true form.—H.

#### SEASONABLE CULTURAL NOTES.

THE earliest inserted batch of cuttings in a closely fitting propagating case or under handlights in a cool house will by this time have become nicely rooted. To strengthen the growth, air should be admitted by tilting the lights on one side a little at first, increasing the quantity as the young plants become inured to the air. Any cuttings that flag should be placed in a separate light so that they can be kept closer until they will bear exposure freely. The strongest growing varieties are those that root first. When the plants will bear full exposure to the air without flagging they should be stood close to the glass in a cool house so that the growth will be stocky. Much depends upon the manner in which the foundation of the future plant is laid.

I fear many plants are spoilt during this stage: they either are too much crowded or have too warm quarters assigned to them. *Chrysanthemums* should never be subjected to artificial warmth beyond what is necessary to keep out frost. If this rule is strictly adhered to we should not hear so many complaints about the excessive tall growth of certain sorts which are really under favourable conditions naturally the opposite. A shelf suspended to the main rafters in a cool house affords a capital site for the young plants until they are ready to be transferred to the frames. The shelves may be about 9 inches wide, according to circumstances, and on each side there should be a groove to run the water off to one end. Here the plants will obtain abundance of light and air, which is just what is required. The plants during this stage should be carefully watered, never allowing the roots to remain dry for any length of time. When the plants are thoroughly well rooted and before the small pots in which the single plants are growing are quite full of roots, they should be shifted into larger ones. One of the greatest mistakes a cultivator can make is to allow the roots to become matted together before the plants are transferred to larger pots. The advantage of striking the cuttings singly in small pots will now be apparent, as the plants are easily repotted without giving them a check. When several cuttings are placed in one pot, the disintegration of the soil from the roots that must of necessity take place in transferring them to single pots must check the growth. As it is not wise to use pots too large to flower them in, some thought must be bestowed upon this phase of culture at the present time, or when the time comes for the final potting it may be found that the plants already occupy pots too large to admit of their going comfortably into those in which they are to flower. For single plants pots 9 inches in diameter are large enough. If larger are in stock—say 10½ inches or 11 inches—I advise that two plants be grown in each; they grow equally well, less space is occupied, and surplus pots are utilised. The present or first shift from the cutting stage should be into those 3½ inches in diameter. The next time, if 5½-inch ones are employed, no difficulty will be felt in finally transferring them to the flowering size.

The soil used for this first potting should consist of two parts fibrous loam, one part leaf soil and one part spent Mushroom-bed manure, with a free admixture of sharp silver sand. If the loam is inclined to be heavy, add crushed charcoal freely. For the greater convenience in potting pass the compost through a coarse sieve, rubbing the fibrous pieces through also. The pots should be carefully drained and quite clean. Over the crocks place some of the rougher parts of the soil and pot firmly. If the soil is moist when used, as it should be, no water will be required for a day or two. Return them after potting to their former position on the shelves till the roots run through the soil to the sides of the pots. Any plants that need support to encourage them to grow erect should have a small stake placed to them.

E. MOLYNEUX.

## FLOWER GARDEN.

### THE AMERICAN ALOE.

(AGAVE AMERICANA.)

THIS is now a roadside weed in many tropical and sub-tropical countries, but it is not usual for it to be met with grown permanently in English gardens in the open air, even in the most favoured parts. In Mr. Dorrien-Smith's garden at Tresco Abbey, Scilly, there are good examples of this and other species of Agave which have withstood for years the winter's cold of that island without suffering, and in the gardens of several of the towns in South Cornwall the American Aloe is to be seen here and there as an outside plant. The plant shown in the accompanying engraving is in the garden at Tredarvat, Penzance, Cornwall, and it is an exceptionally large and healthy specimen for such a position. This plant will bear 6° or 8° of frost, or even more if the atmosphere is dry. On the Riviera it is abundant not only in gardens, but on roadsides; and on waste land near the sea one meets with large colonies of it in all stages of development, from self-sown seedlings to huge plants bearing pole-like flower-stems 25 feet or 30 feet high.

It is popularly supposed that the American Aloe takes about a hundred years to grow to the flowering stage. When starved it may live to that age, and even longer, without flowering; but in the tropics it flowers—"poles" is the correct expression, I believe—when from seven to ten years old. In South Africa it is used as a fence plant and lasts about ten years. Very strong plants have leaves 9 feet long and form huge rosettes 12 feet high by about 15 feet through, which when crowned with tall "poles" bearing large candelabrum-like heads of yellow flowers are very striking.

There are several species of Agave in flower now in the succulent house at Kew. As a rule all Agaves—and there are nearly 150 species—perish after they have bloomed once, but there are some which flower annually or at more distant intervals, and do not suffer in consequence.

W.

**Verbascum phœniceum.**—An apology is due from me to "J. E. N.," who recently sent a photograph and description of this plant to THE GARDEN, and I have now no doubt that the name was quite correct. I trusted too much to fifty years' experience in my own gardens in four different counties, but it appears that the experience of Mr. Arnott and Mr. Burton as well as of "J. E. N." is exactly the reverse of mine, therefore my negative evidence falls to the ground.—T. H. ARCHER-HIND.

—It is curious that this plant has never ripened seed with Mr. Archer-Hind, as it used

to seed freely with me in another garden a few years back. As regards varieties, too, Mr. Archer-Hind's experience differs widely from mine, for in several batches that I raised there was a fair proportion of white-flowered ones and many other shades of colour, from pink to deep purple-red. An important point to bear in mind regarding this plant is that the sun causes its flowers to droop. It does perfectly well in shade, and when direct sun does not reach the plants, the flowers remain open and fresh throughout the day.—A. H.

### THE GENEVAN PLANT PROTECTION SOCIETY.

TO THE EDITOR OF THE GARDEN.

SIR,—Allow me the shortest possible reply to M. Correvo's letter appearing in your issue of

was, I believe, M. Correvo's reply which first informed me of the laws in question, and that I have never taken any part against them. That which I need alone ask leave to add can best be said by reference to Mr. Ewbank's most timely and instructive note. This makes it clear that he is under the impression, as I know are so many others at home and abroad, that M. Correvo's usual practice is to collect blooms and seeds only of alpine plants (but not their roots), and not to sell collected plants. How could Mr. Ewbank gain any other impression if (as I am sure in this case) M. Correvo acted as described by Mr. Ewbank on the occasion to which the latter refers? For there is little or nothing that I can recall in all that M. Correvo has (publicly) written to correct that impression, and there is very much to confirm it. Further, his advertisements of his nursery (circulated by the association through hotels and otherwise) conveyed (if they do not still convey) the same impression, and no other. I assert with complete confidence and knowledge, and am prepared to prove my assertion before any tribunal, that that impression is completely erroneous; that he freely collects plants annually himself and by others, and that it is part of his business to do so. Mr. Ewbank refers to Eritriehium, and Androsace, and Gentians as plants which (he can testify) M. Correvo held sacred from the trowel. It is within my knowledge that in all three classes M. Correvo has collected for sale freely.

M. Correvo refers to my allegations as "malicious insinuations." What I want to know is how far he denies their truth. Whether or no they approve or disapprove Mons. Correvo's modes of proceeding, I believe that all fair-minded persons interested in the general subject of alpine plants will agree that it is unsatisfactory that the "censorship" over "collectors" should fall into the hands of one who is himself a collector, and who has every interest to license himself very liberally. As regards the rest of his curious and varied compilation of charges, I can happily afford to treat them with contempt. The motives are obvious, and I must wholly decline, even in self-defence, to afflict GARDEN readers with what I am fearing might really come to be thought of, however erroneously, as a quarrel between rival nurseries. One point, however, has really some little general interest, viz., how far should a nursery follow popular and garden nomenclature when it differs from botanical? Whatever may be thought on that matter, I imagine that those many botanists who are competent to judge him will be tickled at the spectacle of M. Correvo laboriously "straining"

The American Aloe at Tredarvat, Penzance. Engraved for THE GARDEN from a photograph by Mrs. Ross, Trevean.

January 12. He now alleges that four years ago I accused his society of being the authors of the Phylloxera laws, &c. To use the mildest language, this allegation is a gross misrepresentation, as M. Correvo cannot but be aware, unless he has burnt my letters to him on the matters he refers to. The facts are these: Four years ago a well-known plant-lover made to me an accusation that M. Correvo, or his association, took means to stop the collected plants of others at the Swiss frontier. I passed on to M. Correvo, and to him only (and surely this was no unfriendly act to him), the particulars of this charge, which was never my own. He promptly met it, gave the explanation which he indicates, viz., the existing Phylloxera law. This I at once forwarded to the proper quarter and set the matter right. It would thus not be incorrect to say that I was the means of disposing of the charge. It is simply false to charge me as the author of it. I may add that it

in public at such a comparative "gnat," when they have so frequently observed him "swallowing camels" without any apparent difficulty or discomfort.—H. S. LEONARD.

—Why M. Correvo should claim so much credit in the matter of seedling alpinists I cannot understand, unless in fact he keeps two distinct sets of plants. I formerly used to get an occasional consignment from him, but they were invariably collected plants which he sent, generally placed in pots a short time before they were started off, and they as invariably died. Two friends of mine, both holding distinguished and responsible positions in the horticultural world, who were in his place at Geneva some time ago assured me that they saw little else but collected plants there. I do not object to collected plants; many thousands come here annually. Of course they require some care to become established, but when they are established, who knows or cares whether

they were raised from seeds here or on their native mountains. This hue and cry about collected plants is all nonsense. I should like to ask how many home-raised seedlings can be had of say *Azalea procumbens*, *Matthiola Valesiaca*, *Rhododendron Chamæcistus* and many others I could name. Really the only point is that the plant shall be established, either in a pot, or in the open ground. This being so, the rest is easy. Such plants are capable of thriving elsewhere under ordinary conditions, but when collected plants are sent out as established, and in that belief are treated as such, disaster is pretty certain to follow.—T. SMITH, *Nerry*.

## NOVEMBER AND DECEMBER FLOWERS IN SOUTH DEVON.

TO THE EDITOR OF THE GARDEN.

SIR,—I read with some interest the article on p. 496 of THE GARDEN headed "November in South Devon." My experience as to temperature and weather has been much the same as that of your correspondent, and the wet has interfered greatly with all gardening operations. There was a fair amount of bloom in the open throughout November, and this state of things continued in a less marked degree through December. Chrysanthemums have been very handsome, producing as large blooms in the open in many cases as in pots. I formed a small plantation in the back garden, chiefly of last year's plants, and have had a continuous supply of cut bloom till the frost came. On November 24 I had the following varieties in beautiful bloom outdoors: Vivian Morel, Gloire du Rocher, Beauty of Exmouth, Florence Davis and several others. Two or three plants of Florence Davis continued producing fine large blooms till the last day of December. There are still flowers on the plants, though at last much disfigured by frost. It seems to me one of the best for outdoor planting. Besides Florence Davis I have during December had the varieties Louis Boehmer, E. W. Beckett and W. A. Manda blooming well in the same plantation. The last-named is still fairly good in spite of the frost, though the flowers are small and, through never having been disbudded, a little crowded.

As regards other plants, I have had the following in bloom outdoors during November and the greater part of December: Chrysanthemum frutescens, China Roses, splendid clumps of *Schizostylis coccinea*, *Laurustinus* and *Arbutus*, yellow Jasmine and several *Antirrhinums*. Throughout November and until the early part of December I had a fine shrubby *Alonsoa incisa* producing a mass of scarlet blooms on one rockery, while at the base of another an *Ourisia coccinea* continued for a long time to produce its red trumpet-like flowers, the soil about it having been made very heavy and firm. At the back of an old rockery, and sheltered to some extent by a wooden fence and some *Cupressus macrocarpa* behind, is a fine shrub of *Genista fragrans* (*Cytisus racemosus*), which I found when I came to Teignmouth in June, 1893. Many of its higher shoots were cut down by the frost of January, 1894, though the shrub as a whole passed well through that winter. This winter it has not suffered appreciably yet, and it was in beautiful bloom on Christmas Day. No doubt it will now have a rather severe check. Besides the above decidedly half-hardy plant, I may mention that most of the *Calceolarias* in my garden survived the short, but very severe frost of last January, and have done well this year, and also the *Eschscholtzia* (usually regarded as an annual). This last is in

a corner between a clump of Pampas Grass and a *Cupressus* hedge, and was here when I came. It shows no sign of dying. I believe the plants must have passed through the previous winter, when the house was unoccupied, and this was certainly the case in the garden of the neighbouring house where the *Calceolarias* are quite shrubby and have lived some years.

Returning to plants in bloom in December, there were cut on Christmas Day or picked the day before, besides Chrysanthemums and other plants mentioned before as in bloom earlier in the month or in November, two distinct species of *Veronica* (a white-flowered and a reddish purple species), one or two *Periwinkles*, a white *Godetia*, and a *Carnation Carl Selury*. This *Carnation* has been in bloom outdoors more or less abundantly since August. It is still in bud. This seems very remarkable for the time of year. Another most abundant bloomer which was still in flower in October was *Carnation Meta* (one of the section known formerly as *Painted Ladies*), the upper side of each petal being cerise and the under side white—a beautiful combination.

The frost and rather severe cold have at last come, and we have had the thermometer down as low as 27° or thereabouts for several days. I find it rather trying for my greenhouse plants, the warmest part where are several *Orchids* having gone down as low as 41° in the night, this at a time when *Laelia Dayana* is opening a fine bloom, the lip of which, I fear, may be rather deformed in consequence, and with *Laelia anceps*, *Oncidium unguiculatum*, and *Odontoglossum Rossi* doing their best also to flower shortly.

One *Chrysanthemum* continues to ornament the greenhouse well—W. W. Coles. One plant of this is just opening some fine blooms, and another has had very beautiful flowers for some time. It seems to me specially good for late flowering.

E. F. CLARK.

Teignmouth.

## FLOWER GARDEN NOTES.

PROPAGATING.—The question of the propagation of summer-bedding plants from cuttings will soon require attention, and although the actual numbers of such plants show a steady decrease with each succeeding year, the fact that nearly all that are used are spring-struck stuff is bound to make the propagator busy at this season of the year. If there is no special propagating house with hot water to supply the bottom heat, a substitute must be found for this in the shape of a rather deep pit well filled with good Oak or Beech leaves, with a little stable manure added in thin layers as the work progresses. There should always be the means provided of working inside the propagating pit, and if these do not already exist, it is advisable to throw out enough soil to allow for head room. If the pit is not of sufficient depth, leave space for a narrow path at the back and run up a slight wall, or, failing this, a fence of stout slabs to keep the heating material together. This may sound a very rough and ready arrangement to those who are provided with the best appliances, but it must be remembered that many gardeners have to furnish a lot of stuff under rather awkward conditions. One may regret the necessity for this, and advocate specially in such cases the strengthening of the herbaceous class, but until this is done and beds and borders have to be filled with other things, it is simply a question of doing the best under existing circumstances. With respect to the type of a good bedding plant to be ready by the end of May, it cannot be too strongly enforced that one thoroughly good plant is worth four or five leggy, stick-like subjects. A typical plant should be sturdy and stocky, breaking away well from the stopping and thoroughly well hardened.

The extensive use of *Fuchsias*, *Begonias*, both tuberous and fibrous, and *Antirrhinums* has greatly reduced the number of zonal *Pelargoniums* of average size, that is the *Vesuvius*, *Amaranth*, and *Jacoby* types, and with plenty of silvery *Centaureas* one can dispense with the *Flower of Spring* and *Bijou* types. I find the dwarf varieties useful for small beds or for massing in quantity round taller plants. *West Brighton Gem*, *Surprise* and *Golden Harry Hieover* are struck singly in small pots and pinched once or twice to ensure a sturdy plant. I am striking a batch of *Turtle's Surprise* this year for bedding. I fancy from its dwarf habit and free-flowering properties it should be an acquisition. The idea is to use it in connection with *Centaureas* or in quantity with occasional plants of *Eucalyptus*. Where any stock of special varieties of *Verbenas* and *Petunias* has been kept over from the preceding season, the stock pots may be placed presently in warmth, so that the young tops may come away by the time the cuttings are required. One of the earliest things to be started should be *Ageratum*. A good stock of it is always acceptable, as it is a wonderfully useful little thing for dwarf bedding arrangements. *Vesuvius* and *Mrs. Clibran Tropæolums* are two very useful plants in their respective shades of colour, and they possess the merit of doing well in poor soil, flowering profusely without rank growth. The propagation of any plants that are of rapid growth and come away quickly into good bushy stuff may be deferred until later in the season, such, for instance, as *Lobelias*, the variegated *Mesembryanthemum* and *Sedum*, and the *Iresines*. Any plants required for special purposes, as early planting in boxes, &c., should be among the first started, the trailing *Campulanas*, white and blue, *Harrison's Musk*, *Ball of Fire Tropæolum*, one or two good Ivy-leaved *Pelargoniums*, as *Mme. Thibaut* and *Jeanne d'Arc*, and a thoroughly good strain of *Petunia* are examples of such requisites. Young plants of *Heliotropes*, *Fuchsias*, and *Begonias* that are required for a similar purpose may also be moved along to be ready at the same time. Any herbaceous plants required for special work may also soon receive attention. Autumn-struck cuttings of *Antirrhinums* and *Pentstemons* may be boxed off or planted out in frames if any such are available, and rooted slips of *Phlox*, both the early and late-flowering varieties, inserted singly in small pots. Any stock of herbaceous *Lobelias*, too, that had to be lifted and have been wintered in boxes may be gone over soon, divided and re-boxed, allowing sufficient room so that they can presently be transferred to the open ground without any injury to the root. In this list of plants may also be included the *Marguerite* strain of *Carnations*, which are perfectly hardy and come safely through the sharpest winters. When kept on through the winter the grass should be thinned out, the best shoots pegged here and there to cover the ground, and a little soil or peat Moss manure where this is available shaken in among the plants. Seed of this strain can be sown early in February in boxes and placed in a vinery at work or in a propagating pit fairly well up to the glass, and if the seedlings are pricked off into a suitable compost so soon as they can be handled, nice sturdy little plants are available by the end of April.

Whilst on the subject of herbaceous plants I should like to note that if any small bits of new species or varieties are acquired, they should be planted in the nursery beds pending the opportunity of increasing as soon as practicable. In common, doubtless, with many others, I used to give them a place at once on the herbaceous border, the result being a wonderfully mixed up affair, with not enough of any one plant to make a creditable display. The spell of frost last week afforded an opportunity of finishing the mulching of herbaceous borders, enough peat moss manure having been saved for the purpose, and as there was a little to spare, the *Carnation* and *Viola* beds received the benefit of it. Any that can be obtained from the present time through next month will be transferred to the beds of *Polyanthus*.

**PRUNING DECIDUOUS SHRUBS.**—We have taken advantage of the milder weather to run through the quarters of deciduous shrubs that were planted (grouping species together as much as practicable) on sites from which brakes of old Laurels had been removed. There is a remarkable difference in the yearly growth of such young shrubs: some seem, as it were, to steady themselves with early flowering, as the Altheas and Ribes, and make little headway, whilst annual growth on Weigelas and Syringas is very rank. The pruning is naturally only a matter of heading back a very rank shoot and cutting anything awkwardly placed to a good break, as well as keeping the plants clear of each other. Cuttings are taken of all those things that strike readily in this way, and a few layers put down of specialities that it is desirable to grow into nice sized plants as early as possible. There is little room now between the shrubs for other things, but where an open space is to be found it is filled with a few Foxgloves, an occasional bit of *Chrysanthemum maximum*, and a few other tall herbaceous plants that are suitable for such positions and stand out well between the shrubs. Several clumps of *Lilium candidum* were put in with the shrubs, and these remain, furnishing us, as a rule, with some very nice flower-spikes comparatively free from disease. E. BURELL.

Claremont.

**SIEBOLD'S PRIMROSE.**

NEXT to the popular Chinese Primrose the many varieties of Siebold's Primrose are without doubt the best of a large family for pot culture. Those who have seen the fine clumps in pots staged at the Auricula show in April, or the remarkable exhibits of them made by some two or three trade growers, will admit that of the hardier Primroses these are the most pleasing, varied and beautiful in pots. It seldom answers to allow pot clumps to remain in the pots over one year, as in such case the crowns and leafage become so crowded that they are weak and often incapable the succeeding or third year of producing flowers. Just now that roots are resting is the most suitable time to break up the pot clumps, select the crowns into sizes, and then re-pot. Six-inch pots are the best for ordinary purposes, and where the rhizomes are stout and carry strong crowns, then about eight or nine of them should suffice to fill a pot of the size named. Smaller roots may be planted more thickly, as probably few of them will flower, but all may make good crowns to bloom in succeeding years. In some cases, notably in nurseries, it is the rule to plant these crowns in shallow pans, and then when in bloom to lift the plants and block them more thickly into pots, so as to give an equal head of bloom. In other cases crowns are put singly into small pots, and from these turned thickly into larger ones. It is best, however, to select crowns that are strong and place them in pots as advised, for the bloom product in such case is sure to be good. The growth is even and compact, the leafage forms a capital base, and the heads of bloom rising out from it help to render the entire clump a handsome object.

Japanese Primroses like a compost of good turfy loam, old decayed manure and sand in suitable proportions. The pots should be filled up to within about 1 inch of the top with this compost, and it may be gently pressed down. Then when the rhizome crowns are evenly laid on the soil, gently pressed, covered with half an inch of fine sandy compost, watered, and then stood in a cool frame, a good start has been made towards the furnishing of a most useful and valuable lot of pot plants to flower freely in the spring. Ordinarily, the roots of these Primroses are hardy, but perhaps they suffer more from damp than from frost. Still,

it is well to keep them somewhat protected, yet not covered up too closely, in a cold frame lest damp should prove more harmful than frost would have been. Growth ensues very much according to temperature, but little or no root-action follows until leafage breaks, and if kept cool that is not until the winter has well advanced. If heat be permitted it should be of a very gentle kind, the pots being stood on a greenhouse shelf near the glass so that the foliage be not unduly drawn. The bloom-stems then soon break up, and where there is enough roots potted so that a succession may be maintained, it is thus very easy to have *Primula Sieboldi* in bloom in a greenhouse for at least three months. Except *Primula sinensis*, there are few Primroses, not even the garden *Polyanthuses*, that can be induced to flower over so long a period.

*Siebold's Primrose* will in favourable conditions do well outdoors treated as a hardy rock plant. Its impatience under moisture renders an elevated position on a rockery the best. For this purpose the dark red coloured forms seem best adapted. When so grown bloom comes in May and June, and the colours are richer and deeper than is the case under house or frame culture. Of course, too, the leafage is less drawn, but good clumps of such a variety as *laciniata* have been seen when in full bloom as amongst the loveliest of Primulaceae. Varieties are so many, that it is needless to enumerate them. They can be found in various trade lists, and when well grown as advised always prove to be very charming pot plants. A. D.

**ABOUT PLANT HARDINESS.**

I TAKE it that though the term "hardy" has a wide and useful application for us as English gardeners, it is, nevertheless, a relative or vague term. It is true that in regard to hundreds of well-known species the term may be in every sense of the word correctly employed, but when we take into account the vast numbers of species that during a man's lifetime may be introduced, to say the least the term "hardy" cannot equally or for all of us be reliably applied. We know that the native country or habitat of a plant is no certain guide as to whether it will prove what we generally understand by the term hardy in cultivation in our open gardens. It is a very common occurrence when amateurs are comparing notes for one to say, "I lose that plant every winter," and for his friend to say, "It goes on all right with me," and then on further inquiry, very often there is no ready evidence of much difference in the two climates, and certainly nothing in the way of a lower temperature on the part of the one who loses his plant to suggest that it has been lost merely from intenser cold. I say this is a very common occurrence, and I think we may reasonably at once despatch the idea that want of hardiness in a plant or enduring properties during a winter is in relation merely to the amount of cold in a given district. Doubtless the variability of our winters is alone accountable for the loss of many plants that under other conditions, say those of a covering of snow or even fewer or less wide variations of temperature, might come through safe even with more cold.

To the close observer very simple matters have led to important results. For instance, I find I can grow on an eastern slope sharply inclined some plants that do not in the same garden survive a winter on a similar western slope. This may not seem much to cause all the difference, but if we inquire into it, it implies a great deal. If you put the spade into the soil during winter, though the quality and texture of the soil may be alike in both cases, you may find the soil of the western slope soddened with wet and the other comparatively dry: and when we remember the redoubled grip afforded to frost by the agency of wet in the

land, it may amount to a great deal in the way of life or death to plants that are known to be, as it were, just on the dividing line of the "hardies" and the "doubtfuls." In speaking on this point I have especially in mind my experience with two or three plants, viz., *Onoclea sensibilis*, *Agapanthus umbellatus*, and *Gentiana ornata*.

On the other hand, I admit that there are many plants that are perfectly hardy, though I know scores of instances both in my own and other gardens where newly-planted specimens have simply been converted into pulp from top to bottom of their roots during winter. This occurs with many plants that might be mentioned, but I will only mention one or two in order more effectually, perhaps, to show that it is more a want of skill on the part of the gardener than of hardiness on the part of the plant. Properly treated, nearly all the *Alstroemerias* I venture to claim as hardy for Yorkshire, but certainly that statement must be qualified. It is the habit of all the *Alstroemerias* to embed themselves deeply in the ground, but if the planter in the case of a young plant places at what we may term for our present purpose the young specimen at its normal depth at first, it might not grow at all, and therefore if planted near the surface the roots should be protected for one or even two winters with a warm mulch either of manure or straw until the roots normally place themselves in relation to the surface. You might think it strange that a similar thing occurs with the favourite *Tropaeolum speciosum*, so hardy in Scotland. I question if half the difficulties we hear of in relation to establishing this plant are caused by anything more than the injury that occurs from wet and cold in winter to newly-planted specimens which of necessity are nearer the surface with their vital parts than the roots would be naturally in the case of an established plant. The roots and growing plants of this, like the *Alstroemerias*, may often be found at a depth of 2 feet to 3 feet, and a skilful gardener will afford his young plants surface protection during winter until the roots find their normal place. To further confirm this, when once you have well established this plant its roots are difficult to kill or eradicate. In short, to give many plants a fair test for the quality of hardiness we should know something about their root habit, and should never forget the fact that among plants that may fairly claim the property of hardiness there are as well hardy plants with tender roots as hardy roots with tender tops. To make what I mean a little clearer, the tender roots of *Alstroemerias* will send forth their young growths in spring that not nearly suffer so much from late frosts as a common Wallflower: and, on the other hand, the *Dicentra spectabilis* has a root which, no matter how near the surface, zero frosts cannot injure, but its early sprouts suffer with 3 or 4 of frost. I am now, of course, merely speaking to the point, that a hardy plant may have tender roots with hardy tops just the same as a tender-topped plant may have the hardiest of roots, and that the salvation of the tender and deeply-rooted species is only to be found in their deeply-rooting habit, and that the skilful gardener must nurse his young specimens accordingly for a time. There is, however, this important difference in the two classes here contrasted. In the case of the hardier rooted species you can afford to be more indifferent, as cold does not kill the plant, but in the case of the tender rooted subject, which from necessity as a young plant is abnormally near the surface with its roots, it must be killed unless you afford artificial protection to the artificially located roots.

Again, there is a form of plant hardiness which may be described as constitutional from culture as distinct from what one might speak of as the natural hardiness of a plant. This, looked on in the sense of contributory hardiness, is an important feature in the case of many species, say, bordering on the doubtful, as, for instance, in the case of species which generally have a liking for lime, as the Crucifers and Caryophyllac. The species of these orders are, I think I may safely say, of a hardier constitution when grown with

plenty of lime in the soil. It seems, so to speak, to give bone or robustness to the plants. Corresponding hardness of constitution, though otherwise perhaps of a different nature, comes about also in the case of most species grown with a full exposure to sunshine, other conditions being equally adapted for the plants, and when the subjects are not those naturally affecting shady positions. Or, to speak in more practical or every-day terms, skilfully and well-grown specimens are hardier than the individuals of the same species not well grown. I think this is so, though I know there are good plantmen who hold that a plant cannot be made hardier by culture or acclimatisation than it really is inherently. But this brings us again to the same point, and we have to ask, what is hardness or the inherent degree of the hardy property of any given species, and what are the conditions that enable us to arrive at a fair test? Take a common plant—the Wallflower. I know market growers who cultivate this and experience fear and trembling all through the winter for their broad plantings lest they should be killed, and I know others who have crops that rarely or never suffer in highly calcareous land, and to show that the opposite results are not affected merely by conditions of weather, there is to be seen, besides the hardier condition of the lime-grown crop, a habit of plant very different indeed, though the seed has all been of the same kind. The dwarfier, more twiggy and less leafy habit of the lime-grown plants clearly shows that their growth or culture has caused a change that has rendered them better able to stand the winter.

To show that some plants may be less hardy in captivity than in the wild state as regards cold merely is no difficult matter. When we take the records of the altitude and degrees of cold of the wild habitats, we directly arrive at the fact that when we rarely have similar low temperatures in this country, it is some other condition or conditions than cold alone which kill our garden individuals of the same species. For my own part, I have come to the conclusion that we get over many difficulties by the simple contrivance, of whatever form, that will enable us to keep our plants drier during winter, always supposing that the plant is an established one. I know this is no new doctrine, but how often do we find that, though believed in, it is not practised? There is another theory that I have pretty well satisfied myself about that may not be as generally accepted, and it is that, in view of our exceptional winters or climate, we delay the planting of so-called hardy flowers until too nearly in the teeth of winter. I do not believe that the system of late autumn planting could ever have originated on a more tangible ground than that of convenience; it certainly is not the best for the plant; and if we instance the scores or even hundreds of kinds of hardy species that are so treated and yet do well, it is no proof that they would not do better were they transplanted earlier. I have never yet learnt, either by theory or practice, that any plant had its winter sleep as healthfully when newly inserted as when earlier planted, and in which case it had the natural attachment to the soil, as it could not otherwise have when late planted. Perhaps you most completely compromise the late planting practice, by selecting for the purpose pot-cultivated specimens, which carry all or nearly all their summer roots intact, and this fact may be, as I believe it to be, the chief and best argument for pot-grown stock of hardy species. But even those pot-grown specimens remain, as it were, detached from the natural soil during winter when set late, and are liable to suffer unless great pains are taken to make the surrounding soil equable as regards density or texture in relation to that of the ball. We may miss our way with many plants that have capabilities of endurance by unskilled modes of treatment, and inasmuch as plants may die from other climatic conditions than cold, we have to consider the property of hardness in relation to our individual or peculiar climates, and adapt our gardening so that it does not combine, with the drawbacks of climate, to distress and kill our plants,

but rather alleviates climatic conditions, and so helps to sustain rather than weaken such species as may not have a superabundance of capabilities.

Woodville, Kirkstall.

#### THE CULTURE OF THE GLADIOLUS.

THE papers of "Enthusiast" and my old friend Mr. Douglas on this subject have opened out matters on which I desire to say something. "Enthusiast" feels surprised that I should call the Gladiolus an unpopular flower, and adduces in proof to the contrary the immense quantities that he saw at the Langport nurseries of Messrs. Kelway and Son, and also the brisk trade that the firm carried on in cut blooms. But that is not what I mean by a flower being popular; I would rather imply by that whether it was extensively grown and also exhibited by amateurs. I call, for instance, the Rose or Chrysanthemum popular flowers, widely different as they are in character, because the number of growers and exhibitors in all parts of the country is very great. Show after show is devoted exclusively to these flowers, but he would be a daring man who would venture to start a Gladiolus exhibition. The late Rev. Joshua Dix did once get together a considerable sum, and offered some good special prizes at one of the R.H.S. shows at South Kensington. There was but little response and the experiment was never repeated. Therefore, as I have already contended, a flower cannot be regarded as popular which is only exhibited by two or three amateurs, and I quite agree with what Mr. Douglas says as to its being the most disappointing flower one can grow. I have personally known every amateur who during the past thirty years has come forward as an exhibitor. I have seen them one by one retire, and when I have asked the reason, "Oh! I cannot keep the things; they all go wrong." I have also known many nurserymen who have spent a good deal in attempting to get up a collection, but who have abandoned the attempt, saying that it was no use throwing money away on things they could not keep. Knowing what I do of those that have gone before, I am fully prepared for the announcement sooner or later that amateurs in the south have also given up in despair.

Mr. Douglas revives in his paper on the subject a point in which we two have had much controversy, viz., the supposed degeneration of the flower. He has always considered this was the cause of our losses. Perhaps in one respect he and I would agree, viz., that the individual bulbs of any variety, if taken up annually, will decrease in size and probably in vigour of spike. I have known bulbs of six years old from spawn still to give vigorous shoots and good flower stem, but unquestionably these are not to be depended on, and, so far, there is degeneration of the individual bulb, but this does not mean the degeneration of the variety. You can get as good bulbs of Meyerbeer as you could have done the year after it was let out—some thirty years or more ago. In the same way you can also obtain as good bulbs of Duchess of Edinburgh as were to be had five-and-twenty years ago. Now how are these obtained? Not from the division of the old bulb, but from the spawn saved from year to year; and I am surprised to find that Mr. Douglas speaks of these as also degenerating. They will flower in the second or third year and will afterwards follow the same rule as the older bulbs; but then in the cases of most varieties the supply of spawn is kept up, and although it involves some considerable trouble, this appertains to most flowers which are successfully cultivated, whether they be

bulbs or plants. Of course opinions will differ as to the desirability of raising seedlings, and Mr. Douglas's experience does not seem to be very hopeful as to retaining good ones when they are obtained. It is always a pleasing thing to raise new flowers, but it is a vexing thing not to be able to keep them. His experience is evidently not that of all, or else how could Messrs. Kelway and Burrell send out this year varieties which were raised some six or seven years ago? They must have been able to get up a stock. If, therefore, an amateur has both time and space at his command he can very easily follow out Mr. Douglas's directions and raise seedlings. Most of them, as in all seedling-raising, will be worthless, but he may get some gems amongst them. DELTA.

## GARDEN FLORA.

### PLATE 998.

#### THE MUSK ROSE.

(WITH A COLOURED PLATE OF R. MOSCHATA VAR.\*)

ALTHOUGH no other garden flower has such an extensive literature as the Rose, it is surprising that the artistic side of Rose growing has had so little attention. Nearly all that has been done is subservient to conventional methods, whose chief fault is that they represent to us but one aspect of the flower, and that the least beautiful from an artistic point of view. The consequence is that the Roses that nearly everyone knows and grows are those which produce fine double flowers. May they long continue in popularity, but those who want their gardens sweet and gay should not rest content with these alone. Happily, there seems a growing desire to plant the single types of this noble family. It is difficult to find in gardens such Rose pictures as may be seen by the roadside in June, when Dog Roses and Sweet Brier hang in wreaths from the hedges. Yet we may have them, and lovelier ones, too, if the picture that is annually created by the Rose here figured be taken as a guide. This is only one of many single Roses, but, so far as I have seen and grown them, the very best of them all. No words could possibly exaggerate its beauty. The plate here given shows its fine form, size, and delicate colour, but the picture that this Rose makes in the garden is wonderful. Although an old Rose, it is evidently scarcely known in gardens, but it deserves to be brought from comparative obscurity. In the "Rose Garden," Mr. W. Paul says that the Musk Rose is supposed to have been introduced into England about 300 years ago, and the scent of its flowers was thought to somewhat resemble that of Musk. The plant is described as being of rambling habit, producing its flowers in large clusters late in summer. Under this as being the type are enumerated several varieties, one of them being named *nivea* and thus described: "Flowers white, shaded with rose, large and single, form cupped, growth robust." This is quite in accordance with the character of the Rose here figured, and as the plants came to us under the name of *moschata nivea*, this no doubt is its correct name; but as to its origin or history I can give no information at all. The important point of all, however, is its value as a garden Rose, and there will be few to compare with or equal it for covering a fence, making a hedge, or to

\* Drawn for THE GARDEN by H. G. MOON at Gravetye Manor, Sussex. Lithographed and printed by Guillaume Severeys.

ramble in perfect liberty over some low-growing tree. It appears to be thoroughly hardy, the fence it clothes being open and fully exposed, and the growth is vigorous, although the plants are in poor, stiff soil. It has only one season of bloom, and I have never noticed the slightest tendency to secondary flowers in autumn, but it comes in welcome succession to the early Roses, being usually at its best during the middle and latter half of July, and lasting altogether about six weeks. The trusses of bloom are enormous, many of them having from thirty to forty buds and flowers in a cluster, and every one comes to perfection, whilst from six to ten flowers may often be seen fully open in one truss. The buds are of a lovely pink colour, and there are exquisite shadings of pink in the flower when first expanded, with a cushion of the richest yellow anthers in the centre, much brighter and more beautiful than they appear in the plate, retaining their colour for a long time, and adding considerably to the effect. The leafage, of a glaucous or grey-green colour, is abundant, making a soft and pretty foil to the flowers, which have a powerful and delicious fragrance. The great trusses that crown the strong shoots when cut continue to open their buds for several days.

A. H.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**FIGS IN POTS.**—Figs, if the fruit is required in March or April, are often grown in pots. Under such treatment they give a good return and are forced more readily than trees planted out. There is also less dropping of fruit, and even small trees bear freely. I have for years grown Figs for early use, and it is surprising how the varieties differ as regards setting a first crop. Such well-known kinds as Osborn's Forcing or Brown Turkey, the White or Black Ischias, and Early Violet are reliable, but even these are inferior as regards cropping if ripe fruits are wanted in March. For later use, say the end of April or May, few varieties can excel Brown Turkey. I have seen Negro Largo recommended for early forcing, but I have never got what may be termed a fair crop. For late supplies it is the reverse, as with care this variety may be had later than most others. I admit it is more suitable for pot culture than any other mode of growth, and if grown as large bushes or in a small space it is a grand cropper. The most reliable Figs for very early supplies are the newer St. John and Pingo de Mel, which carry a heavy first crop and may be hard forced with less fear of the fruit dropping. I gathered the St. John early in March last year and of fair quality, small trees in 10 inch pots fruiting freely. Of course, to get fruit at the time named, the trees at this date will be maturing their fruit and will need encouragement in the way of manures and, if possible, some extra warmth at the roots. This latter, unless provided by hot-water pipes and the pots plunged, may be given with leaves and manure, and if the warmth is supplied by fermenting materials the heat should be of a steady nature. The plants should be close to the glass, and with fruits in what may be termed the stationary stage or forming the seeds previous to the final swelling, it is well to prevent a check of any kind. Give tepid liquid manure and also a surface-dressing of some good fertiliser. The roots of vigorous plants will push out into the warm bed, this assisting in finishing the fruits. More attention must be paid to moisture overhead, as if the house is at all moist less syringing will suffice. Excess will cause rust, this disfiguring the fruit and foliage and stopping swelling. Syringing overhead as the fruits approach the final swelling should cease, and even in the case of those less advanced the foliage

should be dry by sunset. Stopping the new shoots is important with these early fruiting trees, as if allowed free growth the first fruits will cease to swell. The young shoots of this season's growth should now be stopped when 6 inches or 8 inches long, and all root or sucker growth removed as early as possible. The temperature for fruiting plants in pots may be 65° or 70° by day, allowing the thermometer to run up freely with sun heat, with 60° at night or 65° in mild weather. Plants struck last year and in small pots should not be kept back, as such potted on now into 10-inch pots will make nice stuff for forcing next year. Pot firmly and give ample drainage. Use good turfy or rough loam, a small quantity of bone meal and mortar rubble, and leave plenty of space on the surface for watering and mulching. Avoid crowding the leading shoots, and if possible train the plants to a single stem, stopping the shoots before a long growth is made to get well-balanced heads.

**SUCCESSION FIGS PLANTED OUT.**—The trees if started early this month will now be on the move and the fruit pushing out freely. A mulch of warm litter and leaves mixed does much good, as it maintains a genial moist temperature and induces a strong growth. Light and sunshine are important details, as, given these, good fruit in quantity is produced. I name these, as often the wood of trained trees is much crowded, and if not well ripened when started into growth at this season, it dies back. At this date any weakly branches should be removed, and the others regulated before growth is far advanced. Syringing several times daily with tepid water will assist the wood and buds to swell, and a night temperature of 50° may now be given, allowing a rise of 10° by day. Figs are often planted on the back walls of vineries, but in such a position good fruit cannot be expected; indeed, fruit of any kind is out of the question. The trees in this house should be treated in the same way as regards stopping, as advised for the earlier pot plants. It may perhaps be necessary to allow a little more freedom of growth in the laterals. The first crop of fruit is mostly produced near the points of the shoots; whereas the second crop is produced from the axils of the leaves on this year's growth. To obtain the latter it is necessary to stop when about 8 inches long, and the break or growth from these shoots will form next year's fruiting wood. As the trees planted out frequently grow too freely, it is necessary to remove some shoots entirely; I prefer doing this when young to leaving them until the knife must be used. It is an easy matter to rub off useless or weak shoots as they appear. As growth increases, more water at the roots will be necessary. I do not advise mulching till the first fruits are well advanced. If given at that stage it will assist both the first and later crops.

**FIG TREES NOT FORCED.**—Many grow Figs in cool houses and get a splendid crop, with, of course, no second crop. Such trees may now receive attention and the necessary pruning. I have seen Figs a mass of shoots and leaves fruit but sparingly. This is the result of crowding the wood and allowing a free root-run. Both these may now be prevented by removing the useless or long naked branches and giving the shoots more room to develop. Barren trees should be root-pruned and new soil given the roots. In giving new soil make it as firm as possible, and thoroughly saturate the old border if at all dry before making it up.

**THE ORCHARD HOUSE.**—Where a house is devoted to mixed fruits much depends upon the grower's requirements as to starting the trees. The orchard house, if heated—which is a great gain—may be often used for such plants as Chrysanthemums; but these should not be allowed to remain in the house after the middle of the month, as a thorough cleansing is necessary, more so where plants which are infested with mildew are housed. All potting should have been done ere this, but in case there has been delay or new trees purchased, no time should be lost in getting the work done. Such trees should not be forced, but be brought on slowly. The trees, if prepared in

the autumn, will at this date need little pruning of any kind, the best results being obtained from those kept stopped during growth, cutting away the useless wood when potting. Before housing, the drainage should be examined where re-potting was not necessary in the autumn; and should worms have closed the drainage, the evil must be remedied at once. Should clear strong lime water fail to reach them, I would not hesitate to turn the plants carefully out of the pots, replacing without disturbing the ball of roots. After housing, free ventilation should be given for a time, occasionally damping over early in the day in fine bright weather and again at closing time. These remarks apply to such as Cherries, Peaches, or Nectarines. As the trees will be in bloom in about six weeks, it is well to fumigate twice or thrice before the flowers open to destroy greenfly. If the house is heated, a little heat turned on while the trees are in bloom will be of great advantage. If such as Pears or Plums in pots are brought forward in this house they should be brought in before the first trees are in bloom, placed at the cool end, and treated as advised for the earlier trees.

G. WYTHES.

### THE KITCHEN GARDEN.

**FORCING ASPARAGUS.**—Where home-grown roots are depended on, a sufficient quantity to meet the demand may be lifted at regular intervals. In view of frost, it is also a good plan to store a good number of roots in a cool shed or outhouse, and cover with 6 inches of leaf mould or fine soil. Where a spare Cucumber or Melon pit efficiently heated exists, no better place can be selected for bringing on a batch or two. Beds also formed of leaves or leaves and short litter, some 4 feet high at the back and gradually receding towards the front, may be built up for the accommodation of frames. The surface should be covered with 2 inches of rough leaf mould, the roots laid on very thickly together, and finally covered with 4 inches of the same material. No water will be needed at first, and the frames may be matted and thickly covered with litter or bracken, this inducing a quicker growth. As soon as the grass appears, light and air must be admitted in order to produce both colour and flavour. Half-exhausted permanent beds may be lifted piecemeal and forced, a new one being made in its place. In forcing Asparagus nothing need be wasted, as the finer grass may be used in soups. In some large establishments permanent forcing beds exist. These are surrounded with deep brick cavities, and pigeon-holed similarly to old-fashioned Pine and Melon pits. Fermenting material is thrown into these and well trodden, the tops of the beds also being covered with the same material. By having three such beds, each is forced one year and rested two. When in active growth, forced Asparagus is much benefited by one or two applications of liquid manure.

**RHUBARB.**—Apples being unusually scarce this year, the earliest batches of Rhubarb brought on in the Mushroom house will soon become exhausted. Presuming that a second batch of roots was introduced at Christmas, the supply may be kept up by putting a few roots in a warm cellar or similar place, to come on very gradually. The general covering on outdoor beds may now be given, first placing the pots over the crowns, afterwards filling in the intervening spaces with good sound leaves, and allowing a foot or so of covering on the top. The use of hot stable manure is dangerous, as it forces growth unduly and ruins the crowns for future years. If there are a few spare pots they may be stood over odd crowns; this will bring them on a week or ten days in advance of the uncovered roots. The present is a good time to prepare a plot for a new bed, and as Rhubarb must have a good larder, plenty of rich manure should be incorporated in process of trenching. If early sorts are to be planted, the old Prince Albert and Reading Ruby may well be included, the former sort forcing more quickly than most others, Myatt's, Linneus and the

common *Victoria* following each other later in the season.

**MUSHROOMS.** These will now be in great demand. As sharp weather necessitates increased fire-heat care must be taken that the surface of the beds does not become too dry. Rather than allow this, cover with a good thickness of dry oat straw. Hay is unsuitable, as it is apt to get mouldy and makes the beds colder. Covering the beds at all times, even in well-heated structures, is profitable, as it lessens the need for syringing a fertile source of decay and discoloration amongst the young offsets. In gathering always remove the entire stem, as leaving a portion in the soil causes rot to spread. Partly exhausted beds may be well moistened with salt water of moderate strength at a temperature of 90 and then be covered with litter, as advised above. The present time is opportune for making up a good-sized bed for coming into bearing at the end of March and throughout April. If there is no room in the Mushroom house proper, a warm cellar or snug, well-sheltered outhouse with good thick walls will answer. The bed should be of extra thickness, 2 feet being none too much, and an extra thick covering must be given. Such beds will often remain inactive for a considerable time, and spring into fertility with longer days and increased sun heat. In firing, rather allow for a slight fall in the temperature than overheat the pipes, as if the beds are in good heart, Mushrooms will appear even if a little later, and they will remain productive over their normal time.

**SEAKALE.**—Where a good breadth of crowns in the open beds was not covered with bracken or litter before the frost came, difficulty will have been experienced in getting the roots out of the ground. Not only should protection be given by the end of November at least, but an occasional batch of crowns should be lifted and bedded in the root shed for convenience. In the space devoted to Seakale in the Mushroom house it is a good plan to have three divisions, so that when a batch is cut for the table it can immediately be replaced, another lot being almost ready for the knife, and a third just on the move. Rather than allow the Kale—when ready to remain in the warmth—to become drawn and watery, cut it and remove it to a cool, not too cold place, and stand it in a pan or shallow basket containing damp moss. This is far better than water for keeping both Seakale and French Beans. Save all good, sound, thong roots, cutting them into 6-inch lengths, and embedding them in sharp soil to callus.

**PREPARING FOR EARLY POTATOES.**—On light workable soils and in fairly warm situations, sheltered borders may now be got ready for the earliest Potatoes. I do not advise the use of solid spit manure, as, independent of its tendency to induce more haulm than tubers, it becomes saturated, and by keeping the soil in the vicinity of the roots and tubers cold hinders early and rapid growth. If these borders were manured and cropped last summer with some fairly impoverishing vegetable, no further stimulant will be needed for these short topped early Potatoes. but it is a good plan to dig in a fair quantity of leafy hotbed refuse—the sweepings of pleasure ground walks, wood ashes, and similar opening materials previously well mixed, these acting as a filter and increasing root warmth. In cases where the soil is at all retentive, digging is best postponed till a week before actual planting, as by opening the surface wet ground becomes wetter, and the crop suffers proportionately.

**CARROT GROUND.**—The preparation of the ground for all first sowings must be pushed forward vigorously whenever weather permits. Carrots prefer a rooting medium the reverse of rich. The lightest, deepest plots should be selected, except for the shortest Horn section, which will do equally well on a shallower soil. Quarters from which Coleworts and Brussels Sprouts have been cleared should be bastard trenched if two years have elapsed since this was done. It tends further to sweeten and pulverise

the soil, as well as to kill grubs if the top is left in a ridged form instead of being levelled down. In March the advantage of this will be seen by the soil breaking down freely. Gaslime may yet be dug in in moderation where wireworm is troublesome, a sprinkling also of soot and wood ashes being most beneficial. Where the soil is not quite so open and free as could be desired, leafy refuse from spent hotbeds may be worked in as a corrective, such soils when cropped with roots being best manured with some artificial composition sown broadcast in spring. A little sheltered corner should also be prepared for sowing a bed of the earliest Short Horn kinds in March.

**CAULIFLOWER PLANTS.**—Plants in handlights should now be examined, as, generally speaking, the first signs of buttoning can by now be discerned. Where such is the case the plants had better be pulled up and thrown away, the soil being well stirred with a small handfork and the tops placed on. This will allow the surface soil to dry nicely for another batch from frames in February. Plants in pits and frames must also be looked over and all bolting batches pulled up. Wood ashes may be freely distributed amongst Lettuce plants where damp or rot is prevalent and a little dry lime added if slugs are troublesome.

**SALADING.**—In no department is regularity more necessary than in work amongst salads, that is if blanks are to be avoided. If Endive in pits and frames in a sufficiently blanched state is not forthcoming, remove a few dozen heads to the Mushroom house, where a few days will make a marked difference in it. Although Endive must be well protected in sharp weather, abundance of air and complete exposure on sunny days must be the rule, or sad havoc will be made by damp. Small lots of Chicory must be regularly got into warmth and sowings of small salading made every ten days.

J. CRAWFORD.

## GARDEN SKETCHES.

### CHAPTER VII.

“There are days which occur at almost any season of the year, wherein the world reaches its perfection,

When the air, the heavenly bodies, and the earth make

A harmony as if Nature would indulge her offspring.” EMERSON.

**JUNE 6.**—It is the hour of sunset. Peace rests upon the hills and slumbers in the valley. Through the stillness comes the rise and fall, the murmur of the last fringed wave that breaks upon the tranquil shore, while from the distant meadows is heard the call of the Rail. The day has been one of gentle showers, and now the air is warm and fragrant as the last rain-drops melt away. Overhead the clouds are breaking. The thin pearly mist that is rising from the valley has so caught the sun's last rays where the clouds have parted in the western sky, that it seems like a rose veil east over the mountain-side and across the undulating woods with their shadowy distances. The evening has reached the perfection of “leafy June,” for the parching drought is ended, and all Nature is revelling in the longed-for moisture. During the past three months there have been cloudless skies and hot sunshine day after day, that have turned spring into summer and hurried the flowers into bloom long before their wonted time, for in all these months there have been only two or three days which brought with them reviving showers. To-day the tide of bloom seems at its height. It is the time of Poppies, and how supreme is their reign, making each spot to glow with their fiery presence. As they flutter in the morning breeze and the sun's rays come aslant through their shining petals, is there any flower more radiant to behold than these flaming Eastern

Poppies! And when we gaze within, how beautiful are the deep blotches, the dark eyes that look up at us from their crimson depth! How lovely, too, are the soft anthers, shedding their blue-grey dust over the velvety striped capsules. Grown in a mass, these Poppies are so dazzling to the eye, that they need some restful blossoms by their side, and these are found to-day in the cool blue-lavender of the Dalmatian Irises and in the lovely white Paeonies that have fallen among them. The rock garden has eagerly drunk in the moisture, and now at the end of a year all trace of planting is nearly gone. The flowers are spreading as they will, and flowing into each other with the prettiest effect. Each week brings surprises of its own as new flowers open and meet, and produce soft harmonies and symphonies of colour. One may arrange flowers as they will, but Nature has a subtle touch, a magic wand, which changes them to “the unexpected,” so that there is always a charming uncertainty in what fresh beauty the day will bring forth. Over many of the rocks the Cheddar Pink (*Dianthus cæsius*) and other single kinds are now trailing. The Cheddar Pink is simply a cushion of rosy bloom, delightfully fragrant. Other dainty blossoms look like the finest white lace, so delicately are they fringed. These Pinks often perish in a border, while between two pieces of rock over which they can toss they will survive from year to year. The beautiful grey foliage and crimson stems of *Rosa rubra*, with little dots of pink (the small clustered bloom) scattered here and there, are fair to see, while *Love in a Mist* sits beneath, at play among the branches and peeps forth with misty blue eyes from among the grey and pink and crimson sprays. Behind the Rose tree, but higher on the bank, are tall spikes of *Ornithogalum pyramidale*, very pretty in their starry height. The defect of this plant is the withering of its leafage before the blossoms are expanded. A plant of the variegated *Hemerocallis Kwanso* being immediately in front of it, has in this instance concealed the decaying foliage. *Lithospermum prostratum* is making its new growth, so I have just top-dressed it with peaty soil into which the stems are pegged down, as in this way the size of the clump is readily increased. Lime in the soil being most distasteful to this “bit of true blue,” it will only flourish where it is absent, in fibrous loam and peat. A colony of *Echeveria glauca* on a ledge of flat ground close by is now in fine bloom, having passed through the winter unharmed. *Androsace lanuginosa*, planted in full sunshine in a deep fissure, is making good growth. It is wonderful what drought these moisture-loving alpine will bear if only they have depth of soil in which to press downwards through the clink of a rock. In the more shaded and damper side of the rock garden a deep crimson *Mimulus* is surfacing the ground next the great bronzy leaves of the Japan Saxifrage (*Rodgersia podophylla*) whose white wands of blossom wave aloft. Then comes a cool patch like the blue sky itself, the perennial or summer Forget-me-not, with a lush green in its creeping stems, that suggests the verge of a streamlet bank. Yonder is the glowing *Mimulus* with its dazzling vermilion bloom flung over a low projecting rock, behind which its moisture-seeking roots are safe from the mid-day heat. Besides this most brilliant of blossoms, the deep purple *Campanula Portenschlagiana* is very luxuriant with its long trails of bloom hanging over the stones that keep the ground of even temperature. *Saxifraga peltata* is in its glossy bright green stage, stretching out its leaves above the white Flax that is now a sheet of blossom. The various Thymes are spreading

into soft cushions that cover the drier portions of the rockwork. The silver-leaved Thyme, with its pale lilac flowers, is growing by the walk and pressing up against the rock, of which in the distance it seems part, having very much the same hue. In the same manner the red-purple Thyme (*Thymus serpyllum coccineus*) is lying against a rock of deeper stain, while the soft, woolly Thyme (*lanuginosus*) is rambling over a flat surface. The golden-leaved Thyme should be grown for its aromatic perfume, and its bright and cheerful aspect in winter when the other kinds become dim.

JUNE 20.—The sea is asleep this evening. Even the reflection of the far purple headland lies shadowed in the tide. The day has been one of exhausting heat to plant as well as human life, and now one passes along the shore to catch the cooler evening air as the water gently lips the yellow sand. The sun's slant rays have cast a rose light across the sea, save where changeful currents beneath make silvery lines. Slowly a white-plumed seagull wings its homeward way with the sunlight on its breast, while overhead the Swift screams wildly as it cleaves the sky. Refreshed by the cooler air we can now visit the flowers in the pleasant twilight, for there is no real night, no darkness between the sunset and the dawn, for ever toward the north the sky is bright and clear, with token that the sun, not far beneath, is hastening on his way to rise again in splendour. The noble Californian bush Poppy (*Romneya Coulteri*) has just opened its first flower, a milk-white blossom with a boss of golden stamens in the centre. It is against a sunny wall with peat and leaf-mould at its root, and given a copious watering from time to time. The old stems of last year were cut entirely away as soon as the young growth was a few inches high, and the weakest were later on thinned out, so that all left are now strong and full of flower-buds. In the walled garden the old Stocks and Wall-flowers have just been thrown out and replaced by seedlings sown last April. Shady weather is always best for such transplanting, but as no clouds are vouchsafed to us and the work cannot be longer delayed, branches of evergreens have been stuck all through the beds, which give shelter from the burning sun, and when watered all over in the evening retain the moisture in a wonderful manner, and once rain comes they will be ready to rush forward. The replanting of the Daffodils has taken up a good deal of time. After two years they had grown so thick, it was necessary to lift and divide them, and this division has so increased their number, that I have now a good border of Emperor and Empress, Sir Watkin and N. Horfieldi. The soil was deeply dug and the Daffodils given back again to their mother earth—for, after all, is not a child safest in the nursing care of its own mother?—and our keeping of them must be ever that of a foster-parent. Then the beds of the incomparabilis section and the seedlings had also to be lifted and divided until there was no more room for planting, and some had to be given homes under the trees. In the fountain garden the white Martagon Lilies among the red-leaved Lobelias are tall and fair, but fairest of all in the evening hours when the sunbeams shine through their stainless petals, and they seem aglow in the misty light. While English Irises are in flower among the Roses, replacing the now slumbering white Daffodils, white Violas are spreading over the verge.

The Bamboos have made early and rapid growth, some of the new shoots being 12 feet high. No doubt a good soaking of water from the hose every week has supplied their need, which seems a moist root-run beneath and hot

sun overhead. The best time for transplanting appears to be just as the new growth begins to push up. One I moved about six weeks ago never felt the least check, and one could perceive its visible growth from day to day. To have the ground beneath shaded with low growing shrubs, or even large Ferns, is a vast help to their well-being, as it prevents parching of the soil, keeping it cool in summer and warm in winter. Good-sized rocks that the roots can run under will have the same effect, but are not always to be had, or may be unsuitable to the position of the Bamboos. Their feathery wands are certainly most graceful, and, moving gently in the summer breeze, give a delightful sense of coolness. No doubt they will be more largely used when better known, as they are one of the most beautiful additions that has been introduced of late years into our gardens, alike pleasing to the eye in winter as in summer.

On the Periwinkle bank the soft golden blossom of the St. John's Wort (*Hypericum calycinum*) is now replacing the blue of the Violets, and Creeping Jenny (*Lysimachia nummularia*) is trailing down under the old Laurel. A very pretty grouping in the rock garden is made by the lovely blue of *Mertensia sibirica* and the indescribable hue of *Mimulus glutinosus*. The fresh blooms of the latter open almost red, and pass through paler shades till they fade into faint orange or sunset glow of amber. A mass of their flowers seen together in all their different tints, with the sunshine at play among them, is a morning glory; but now, in the still hours of evening, they have a beauty all their own beside the cool *Mertensia* in its blue and silver robe.

L. A. L.

(To be continued.)

**Cupressus nutkaensis lutea.**—This is a remarkably distinct form of what in gardens is better known under the older name of *Thujopsis borealis*. The type as a town or suburban shrub is one of the most reliable. Of this I know of an example fully 20 feet in height, the position an exposed one. The variety now noted possesses all the good qualities of the type. Whilst taking into consideration its bright yellow tints in a young state, it should prove a most valuable plant, distinct in every way from both the golden forms of *C. Lawsoniana* and of *Retinospora obtusa aurea*. G.

BOOKS.

THE LIFE AND CORRESPONDENCE OF WILLIAM BUCKLAND.\*

THE place of geology in science is now so firmly established, that it is difficult to understand the almost savage antagonism with which its professors were greeted at the beginning of the present century. We welcome this book. Dean Buckland is certainly one of the most interesting personalities in the field of natural science that the present century has produced—one who, in the words of Professor Boyd Dawkins, "brought about a revival of natural science analogous to the movement in religious thought brought about by Newman and the Oriel school." But what will probably recommend the subject of this memoir most to readers of the book is the kindly, humorous, truth-loving, lovable nature which is there displayed. Buckland was an enthusiast for his science, and he had in a remarkable degree the knack of communicating his enthusiasm to others in a day when the votaries of this science were

\* "The Life and Correspondence of William Buckland, D.D., F.R.S., sometime Dean of Westminster, twice President of the Geological Society and first President of the British Association." By his Daughter (Mrs. Gordon). John Murray, Albemarle Street.

looked upon as scarcely sane. Geology he regarded as the handmaid of religion and as holding the keys of one of the kingdoms of Nature. How he went about his geological researches and of the influence he exercised over the minds of his generation let Mrs. Gordon tell. The book abounds with bright and humorous anecdotes, and there is not a dull page from cover to cover.

PRACTICAL FORESTRY.\*

IN general get-up this resembles Dr. Schlich's book on the same subject, and this, taken in connection with something in the preface, caused one to turn instinctively to Dr. Schlich's volume, at which a ten minutes' cursory glance showed that the resemblance did not end with the outside—although readers are clearly expected to believe that the author of "Practical Forestry" is indebted to nobody but himself. Two societies are conspicuously thanked "for the privilege of allowing the author to make extracts from several of his own prize essays." Not a word of acknowledgment to anyone else. No one, I believe, has attempted to deal with the subject of forestry in a general way without having to acknowledge assistance, and the following parallel columns show how far Mr. Webster's book is free from obligations of that kind:—

"WEBSTER'S PRACTICAL FORESTRY."

Thinning Plantations.

1. At what age should thinning be commenced?  
2 & 4. To what extent should thinning be engaged in? What trees should be removed?

3. What time should elapse between each thinning?

No thinning of young trees should take place until a complete leaf canopy has been established, and it is most important for the welfare of the plantation that a complete overhead foliage covering be brought about as early a date as possible after planting.

At a short period after a complete leaf canopy has been established, the individual trees begin to press against each other, and later on a struggle for existence commences, the stronger specimens gaining the supremacy over the weaker.

Hard-wooded trees require proportionately more space for development than conifers, and the annual rings in the timber of the latter should be narrow in proportion to those of the former, good quality of hard-wooded timber being indicated by broad annual rings, but with conifers the reverse is the case.

Neither your space nor my time permits, at present, of further search for examples like the above; but those acquainted with its author's former writings know how long it is since he began to imbibe Continental principles in forestry, and this last production of his pen may be said to have reached the saturation point. The above extracts from Dr. Schlich are peculiarly his own, and are, I believe, to be found nowhere else; and the parallels from Mr. Webster's book are all to be found within the compass of two or three pages of his chapter on thinning—perhaps the most important in the book. In both cases I have slightly abridged the quotations, but not in any way affected the sense or comparison. I am tempted to compare also Mr. Webster's opening chapter

"SCHLICH'S MANUAL OF FORESTRY."

Thinning.

1. At what age of a wood should thinning commence?  
2. To what trees should they extend? How heavy should the thinnings be?

3. After what intervals should they be repeated?

One of the most important objects in the formation of a wood is to stock the area sufficiently, so that a complete overhead may be established as early as possible. This is desirable for a proper development of the trees. In order to ensure quick closing overhead it is necessary to bring on to the ground a much larger number of plants than can find room for any prolonged period.

Soon after a complete leaf canopy has been established the trees commence pressing one against the other, there is not enough growing space for all, and then a struggle for existence sets in. A portion of the trees outgrow the rest and they rear their heads up to the full enjoyment of the light, &c.

In the case of those broad-leaved species which have the pores in the spring portion of the wood, broad rings indicate high quality, and narrow rings low quality; here heavy thinnings are indicated. In conifers, however, the matter is exactly the reverse.

\* "Practical Forestry" By A. D. Webster. Second edit. Wm. Kider and Son.

on pruning with Dr. Schlich's on the same subject. Suffice it to say that the chapters on pruning in both books are marvels of unanimity.

Mr. Webster has embodied in the book some drawings that were originally contributed to THE GARDEN by Sir Herbert Maxwell in 1876, and has transferred them (very rudely engraved by some inferior process) to his own pages without any acknowledgment of their origin. J. S. W.

#### ARRANGING CUT FLOWERS.

IN the engraving here given, Fuchsias, Passion Flowers, Coleuses, and Maiden-hair Ferns are used with good effect, because each is set out in a bold and informal way. The Fuchsia is a delightful flower for cutting, when its graceful trusses of bloom are well arranged and not hidden with other things. The flowering shoots bend over gracefully, and the dark-leaved Coleus is in bold contrast, whilst the Passion Flower at the base is shown to advantage. The aim in all forms of decoration such as this should be to create an informal and graceful effect, which is not done by cramming the flowers together in a way to deprive them of light and shade, and hide their individual beauty.

**Colour in Ivies.**—The variegated Ivies lose their beauty and become unattractive if not favoured with plenty of light and a maximum of sun. I have a high wall which viewed from one aspect was deemed unsightly. Eventually the wall was covered with a choice assortment of golden and silver Ivies. For a few years the colours remained fairly true, but suddenly the majority of them assumed an ordinary greenish tinge, and although serving the purpose of a screen to the bricks and mortar, have now quite lost their attractiveness.—J. C.

#### ORCHARD AND FRUIT GARDEN.

##### FRUIT PROSPECTS FOR 1895.

THE very dull, sunless season of last year, more especially during the autumn, caused many fruit growers some anxiety as to the proper ripening of the wood, and also whether the buds would be properly developed. Present appearances indicate that no trouble need be anticipated on those points, as fruit trees of all descriptions are full of promise, and unless we have an extremely unfavourable season, good crops of fruit should be the rule this year. I think the copious rainfall since September last, combined with the very mild weather, has been a great boon to fruit growers, as the buds swelled up to a large size very late in the autumn. A few varieties of Apples, including about one hundred Cox's Orange Pippin, had very small buds early in October, but by the end of the year they had attained the normal size. The same also applies to a few sorts of Pears, but which are now all that could be desired. A feature amongst Apples and Pears that have always been very shy bloomers is that this year they are covered with bold fruit buds, and out of a very large collection every tree of all varieties has plenty of fruit buds. Many of these trees last year had heavy crops of fruit, and I believe that the promise to repeat the same this season arises from being supplied with ample food, thus preventing any exhaustion in perfecting the fruit. Plums of all sorts, both on walls and in the open, are more thickly studded with bloom buds than I ever saw them. Angelina Burdett and Reine Claude de Bayay are covered with buds

this year, this having never happened here before. Apricots, Peaches, and Nectarines are all full of promise, with apparently well ripened wood, on which are fine, bold buds. Cherries, again, both sweet and Morello, look remarkably well. Nearly all the gardens that I have visited this winter have equally as good a prospect as we have, and Nature having done so much towards a bountiful fruit year, we on our part should do all we can to aid her efforts. I think if the question were asked, Do we assist Nature, collectively, as much as we ought to do in fruit-growing? the answer in many instances would be in the negative. In the first place, we might

aphis are in more or less evidence in all the gardens I have seen, and in some gardens the attack will be very violent. If this scourge can be reduced early, we not only do much towards ensuring a crop, but also save anxiety and worry. Unfortunately, I have yet to find a safe insecticide that will destroy the eggs of the winter moth, but the two other foes named can in a great measure be rendered incapable in the egg stage by an application of 1 lb. of crude potash and 1 lb. of caustic soda dissolved in ten gallons of hot water and applied warm to the trees in a fine spray. If this solution is put on at the end of February, moistening every part of the

Cut Fuchsias, Coleus, and Passion Flowers.

with great advantage to the trees and ourselves do infinitely more towards the prevention of insect attacks. As I mentioned in THE GARDEN last year, we commence too late in the spring to deal with these foes successfully. For a number of years I began spraying the trees in March, but for the past two years I have performed that operation at the end of February, with the most gratifying results, and as a proof of its value I may state that on about 1000 Plum trees last year we had neither aphis nor other insect pests all through the year. This spring we may expect plenty of these enemies. The eggs of the winter moth (*Psylla mali*) and

quantities of eggs will fail to hatch.

The extra manuring of trees that are likely to bloom abundantly is a great aid and will cause trees to set heavy crops; whereas if not thus treated liberally the strain of producing such a mass of flowers would in many cases be so exhausting that a failure might be expected. Where a comparatively small number of dwarf and wall trees is grown, the thinning of the fruit-buds exercises a wonderful influence, not only on the setting of the fruit, but also on the swelling and size of the same. When I first took charge here there were some Marie Louise,

Louise Bonne of Jersey and Beurré Hardy Pear trees that always bloomed most profusely, but failed to set any fruit. By removing two-thirds of the fruit buds I have succeeded in obtaining good crops of fruit annually ever since, proving that the efforts of production were beyond the strength of the trees. W. G. C.

**Pear Baronne de Mello.**—Until this season I have never had an opportunity of tasting this Pear, although several correspondents have spoken well of it in the pages of THE GARDEN. My tree of this variety is grown as an espalier, and in former years the fruit, though plentifully produced, was always cracked and deformed. The great heat of 1893, however, ripened the wood, and this season the fruit was not only passable in appearance—being not unlike Beurré de Capiamont, with its russet skin—but the flavour was really good. One of the best points about this Pear is its long-keeping qualities. In midland and northern districts it no doubt requires a wall, and it deserves it even in the south, as good keeping Pears of high quality are none too plentiful. —J. C., *Coddington Hall, Newark.*

**American versus English Apples.**—A short time ago a large importer of American Apples sent me a hamper of carefully selected fruits, also some from the Dominion, asking my opinion of them as compared with English fruit. One Apple of each popular variety was sent, and so far as appearance went they were all that could be desired, but with the exception of Newtown Pippin the flavour was decidedly inferior to good English Apples. In justice to Newtown Pippin it must be stated that it was of excellent quality, only slightly behind Cox's Orange, Ribston Pippin, and one or two other highly flavoured varieties grown in this country. In spite of its excellence, however, the sender stated in his letter that annually the demand declined for it, as the appearance is not so striking as that of Northern Spy, Baldwin, and others with a rich colour, but of poorer quality. Another noticeable feature was the great superiority of the Canadian Apples over those from the States, particularly in the crispness and greater quantity of juice. On other occasions I have received similar specimens, which only confirm me in the opinion that even in bad seasons our English Apples are superior to any in the world when well grown, and it is greatly to our discredit that such immense imports of admittedly inferior Apples reach this country. The Australian and Continental consignments are at present comparatively small, but likely to be increased in the near future unless our home growers not only improve existing orchards, but also extend or form new ones on the best and most approved lines. Unfortunately, Cox's Orange Pippin will not succeed everywhere, but where it does well it ought to be extensively planted, as it is always in demand. The lowest price I ever got for this variety was 30s. per cwt., and this winter the grower could have quoted his own price for good samples. Several fruiterers and others wrote me they would pay any price in reason for it, thus testifying in the strongest manner to its superiority over all others, whether American or otherwise.—W. G. C.

**Paradise v. Crab.**—Until we shall have learned how to work up quickly a healthy young stock of our best Apples on their own roots the question of suitable stocks will be ever with us. A side light on this question which may be familiar to many, but which, I confess, was new to me, came out in a chat with a nurseryman a short time ago. While looking round the nursery, which is fairly large and representative, I happened to ask why it was that so few of the young Apple trees were worked on the Paradise and so few of the Pears on the Quince? The answer I got was that it was simply a question of £s. d., and I was taken to a plot where trees worked on the Crab and the same varieties worked on the Paradise at the same time were growing side by

side. The difference in appearance was very striking. Those worked on the Crab were quite handsome specimens, which any buyer, who knew nothing of stock influences, would be sure to select, the others being mere pigmies in comparison. The great majority of buyers, who came to see before purchasing, selected the trees which looked strongest, and as these were the most easily and most quickly grown, the nurseryman's business being to sell, the other trees were not pushed. Whether this policy pays best in the end or not is a question for the salesman to decide, but it must be a source of dissatisfaction to the buyer, who generally wants to see his trees fruiting soon after they are planted and not wait year after year anxiously watching for fruit until the trees reach orchard size or, as is more likely, ignorantly hacking at them each winter with the knife with the idea of making them fruitful, thus spoiling the trees and producing nothing but cankered thickets.—J. C. TALLACK, *Livermore Park, Bury St. Edmunds.*

#### GRAPE ROYAL VINEYARD.

I HAVE read Mr. Douglas's interesting remarks on Grapes at page 1, and am pleased to find he has a good opinion of Royal Vineyard. We seldom see or hear anything of this variety now-a-days, the reason, doubtless, being its uncertain setting character. A noted Grape grower in the midlands wrote to me some time ago asking for some eyes of it, as he knew I grew it. When I sent the eyes I enclosed a few berries. He replied that the flavour was grand, but asked if it was really worth growing, being such a bad setter. If, however, this difficulty can be surmounted, as Mr. Douglas says it can by extra care at the setting period, then it is not only worth growing, but quite indispensable where quality is recognised. My first experience with this Grape was in Worcestershire. When I first took charge of the place the Vines were not labelled, and I did not know what this particular rod was. When the bunches came into flower the first season I noticed they were heavily charged with the minute globules of water of which Mr. Douglas speaks, and as I did not give them any special attention, I did not secure a single perfect bunch. The year following I used a rabbit's tail freely each day at noon, thus removing the globules and allowing the pollen to act. Every bunch set like Hamburgs, swelled off fine berries, and ripened well. From that time I have always been partial to Royal Vineyard. The Vine I now have is inarched on Gros Maroc, and the stock seems to suit it capitally. It does not grow quite so strong as when on its own roots, while the water globules which appear are not nearly so numerous. When in bloom I give it a temperature of 68° or 70° at night, keeping a dryish atmosphere during the day and damping down very slightly in the afternoon when sunny. With even ordinary care it sets quite freely and does well throughout. I think the culture of these high-flavoured Grapes is not sufficiently encouraged by societies offering prizes. I would include a class for them in the schedule at every large show.

In referring to Gros Colman, Mr. Douglas says it requires a house to itself to do it properly. This is no doubt true when on its own roots. If inarched on the Muscat it does its work in a surprisingly short time. I have before referred to the Gros Colman at Kelham Hall near here. This is worked on the Muscat stock, and which, started at the beginning of March, regularly ripens its crop by the beginning of September. The bunches are large, the berries enormous and the colour that of the Sloe. After seeing these Grapes I put a graft on to a Muscat rod. The Vine bore a bunch last summer, and although the house was not closed till February 1, the bunch of Gros Colman was quite black by the middle of July.

J. CRAWFORD.

**A good winter Pine.**—Pine-apple culture, although greatly on the decline in English gar-

dens, is, nevertheless, still carried out in many places. It is not always that good sound fruit can be had at mid-winter, as even the old Cayenne and Rothschild are apt to be discoloured in the centre unless grown under the most favourable conditions. Probably, all points considered, Black Jamaica is the best winter fruiting sort, being seldom found with a black centre. Black Prince, however, a variety apparently little known, ripens most satisfactorily during the dull dark months of winter. The fruit is long, sometimes thirteen or fourteen pips deep, rather narrow perhaps, but very symmetrical, and in colour a handsome bronze. The flavour is good, and large fruits are produced on small plants, a rather cramped root room suiting Black Prince best.—J. C.

**Potash for forced Strawberries.**—In many gardens the Strawberry plants for forcing are far from satisfactory, a large proportion of those that were put in early either being blind, or throwing up weak flower-stalks and very small blooms. Amongst the many manures, both natural and artificial, now to be had, I think muriate of potash is one of the most useful for Strawberries in pots, as, while not producing a gross habit, it seems to cause a great increase in the strength and general good health of the plants, and materially assists the development of the fruit. Unlike some manures, there is no objectionable smell, and if applied while the fruit is ripening it does not affect the flavour; in fact, I believe it improves it rather than injures it. As muriate of potash is a powerful salt, somewhat weak applications will prove far more beneficial than strong ones. A very fair solution is half an ounce dissolved in one gallon of water. This may be given two or three times a week, and if deemed advisable may also be supplied, in addition to any diluted natural manures. The value of the muriate of potash would perhaps not be so marked on plants potted in a heavy soil, but for those in a medium or light soil its effects are very apparent, and will warrant its use in the future. Another advantage that I think arises from employing this salt is that it keeps the soil sweet. When the fruit has attained half its size an application of nitrate of soda, one ounce to each gallon of water, will afford a welcome change in the food and help the development of the berries; but according to my experience any further waterings with nitrate of soda have a tendency to interfere with the flavour when the berries are ripe.—W. G. C.

#### STOVE AND GREENHOUSE.

##### LIVING EDGINGS FOR CONSERVATORY STAGES.

THE time is now quite opportune to draw attention to this subject, on which not nearly enough thoughtfulness is, as a rule, bestowed. It cannot be argued against the adoption of living edgings that they are not easily kept, or that the choice of material is in any way limited, or even that the propagation of the most suitable varieties is in any sense a difficult matter. Hence, where advantage of this additional feature is not taken it must be assigned to other causes. Of their utility and effectiveness there can be no doubt whatever where once they have been adopted in a judicious manner. Hardly two cases may be exactly alike as to the special needs in this case. Once I had charge of a large conservatory with the borders planted out. In this instance I used a marginal edging of *Selaginella denticulata*. Dotted amongst such a growth either Snowdrops or Crocuses were very effective in the spring, these being lifted after flowering, when the *Selaginella* was taken up and relaid. To attempt to keep this kind of edging for two seasons will not prove satisfactory. Palms, Ferns and other fine-foliated plants

formed the chief features in the beds in question, shade during the summer being given. In dealing with plants needing less shade, as Camellias, Rhododendrons, &c., *Ficus repens* would answer well; this would not require renewal every spring. In a light, sunny house the new race of hybrid *Streptocarpus* can scarcely be beaten. At Kew these are used with the best effect in the succulent house. The foregoing are all suitable for cool or average conservatories, but for warm conservatories the subject of the accompanying illustration makes one of the most effective of edging plants either planted out or in pots. It will thrive well either in the sun or when shade, the tinted growth in the former instance being very attractive, whilst the purity of the variegation is equally so in the latter. It is also well suited to ferneries that are not excessively moist.

The foregoing are almost entirely cases of planted-out "edgings," but in pots they still form most suitable subjects for hiding the pots (not always clean ones) of other plants from view. Wherever the side stages are of sufficient width such edgings should be adopted, whilst central stages need never be overlooked, the effect of such edgings adding greatly to the general appearance. Edgings to stages need not be of compact, close growth; nay, rather it is better to have them selected from material that will during the season droop down, adding still further to the effect as a whole. *Panicum variegatum* (I much prefer this, its older name if not its strictly correct one) is an apt illustration of this method for a moderately warm house at any season or for the average conservatory during the warmer months. Imagine, for instance, this pretty Grass intermixed with *Lobelia gracilis* (a sadly neglected plant because not of compact or prim growth). What could form a prettier combination, the shades of blue and white of the *Lobelia* and the silvery variegation of the *Panicum*? The common Musk is another instance; so also is the Giant Musk, but of the two, for pots, I prefer the former. The varieties of the *Tradescantia* that are given at least the warmth of the average stove during the winter will at other seasons serve admirably as edgings in any place where the *Panicum* can be safely used.

Turning to plants that require the warmth of the stove, attention is at once arrested by the effect produced by the use of *Fittonia argyoneura* either in moist positions or comparatively dry ones. As a contrast to this plant, *F. Pearcei* could be suitably employed, or, better still perhaps in some cases, *Cyrtodeira fulgida* or *C. metallica*. Both of these last-named plants are charming subjects either as edgings or for a carpeting amongst taller ones; their brilliant Tydaea-like flowers are very showy. Another good old stove plant for an edging is found in *Torenia asiatica*.

For the very coolest houses, even where the frost is barely or even not excluded, there are *Enonymus radicans variegatus*, one of the prettiest of all edging plants, and *Dactylis glomerata variegata*, also *Eurya latifolia variegata*. As a pot plant the last-named is a specially good edging for decorative groups in other than the growing quarters. The smaller and dwarf-growing *Begonias* of the variegated or Rex section should not be passed over. They seem to be equally as much at home in a house from which the frost is barely excluded as they are in warmer quarters. Ferns, again, can be used to the best advantage as edgings, choosing those of dwarf habit. *Adiantum cuneatum* (of which too much is hardly ever grown), *Pteris serrulata* (better for this purpose than its crested forms),

and the dwarf *Davallias* are cases in point. It would have been possible to extend this list, but sufficient has been quoted under each head. Additions can be made as the circumstances may require.

GROWER.

#### BEGONIA GLOIRE DE SCEAUX.

WINTER-FLOWERING *Begonias* have attracted a good deal of attention within the last few years, and consequently many have been brought forward during that time. Some have proved exceedingly valuable for blooming in the winter, and among the best is *Gloire de Sceaux*, which was first distributed about ten years ago, but was not generally known till a number of plants in grand con-

commences to bloom about mid-winter, and a succession is kept up till spring is well advanced. I have also noticed that this *Begonia* seems to be less affected by fogs than many of its class are. Another variety with more pointed leaves of a bronzy crimson colour is *President de Boureuilles*, worth growing for its foliage alone, but the pink flowers are also very showy. A continuous flowering variety of great value for winter blooming is *Gloire de Lorraine*, one of the productions of that eminent raiser, M. Lemoine, of Nancy. When distributed it was announced as a hybrid between *Begonia socotrana* and *B. Dregei*. The flowers, which are profusely borne, are deep rose in colour. In general appearance it is somewhat like Messrs. Veitch's first hybrid of this class—*John Heal*, but the blooms are not so brightly

*Panicum variegatum.*

dition were shown at a meeting of the R.H.S. in the middle of January two years since by Mr. Jennings, gardener to Mr. Leopold de Rothschild, Ascott, Leighton Buzzard, when a first-class certificate was awarded it. Since then it has made headway, and is, I should say, destined to retain that popularity for a long time. It was raised by MM. Thibaut et Keteleer, of Sceaux, near Paris, and described as a hybrid between *B. socotrana* and *B. subpeltata*. The habit of the plant is stout and vigorous, and it forms a neat, compact, pyramidal-shaped specimen, plentifully furnished with bold foliage of a rich bronzy green tint. The flowers are large, borne in good sized clusters, and of a deep pink colour. It usually

coloured. *B. Gloire de Lorraine* will often flower from autumn till the spring. Lastly, among the best of all the winter flowering *Begonias* are those Chelsea hybrids, *John Heal*, just mentioned, *Adonis*, and *Winter Gem*. Of these the variety *John Heal* resulted from the intercrossing of *B. socotrana* and a summer-flowering tuberous-rooted variety—*Viscountess Doneraile*. *B. John Heal* has bright rosy-carmine coloured flowers, which retain their freshness for a considerable time. *B. Adonis* was obtained by crossing *B. John Heal* with a tuberous-rooted variety. The flowers of *Adonis* are carmine, shaded scarlet. The most recent of the three is *Winter Gem*, a hybrid between *B. socotrana* and a crimson-scarlet

tuberous-rooted variety. *Begonia Winter Gem* is perhaps the most useful of the three, its scarlet-crimson flowers being borne in great profusion, so that it is a striking object throughout the winter months. It will be seen from the above that we are greatly indebted to *B. socotrana* for some of our finest winter-flowering *Begonias*. It was the subject of a coloured plate in *THE GARDEN*, March 11, 1882, and at the time great expectations were formed of its value to the hybridist, which expectations have now been fully realised. *B. socotrana* itself is well worth growing for the sake of its blossoms, which are borne during autumn and early winter. H. P.

**Kentias.**—Some years ago, when Palms in small pots first became popular for indoor decoration, and were then largely taken in hand by a few of our market growers, the principal kinds grown were *Latania borbonica*, *Areca lutescens*, *Corypha australis* and *Scaevola elegans*. Time has, however, changed all that, and now the *Kentias*, particularly two species—*K. Belmoreana* and *K. Fosteriana*—are grown in far greater numbers than any other Palm. Of these, *K. Echinoreana* is the dwarfier and more finely divided, *K. Fosteriana* being taller, with the segments of the leaves much broader. Good established plants of *Kentias* that have been inured to a greenhouse temperature will remain in good health in a room for years, provided frost is excluded therefrom and the plants receive a reasonable amount of attention. Irregular watering and an accumulation of dirt on the foliage are two of the most important reasons that cause plants in dwelling-houses to become unhealthy. These Palms will succeed in much smaller pots than many suppose; indeed, they will stand for years without repotting, and when the pots are full of roots an excess of water will rarely harm them; whereas, with a quantity of soil into which the roots have not yet entered the result will be totally different. In some market nurseries these two Palms are grown in such enormous numbers, that it is difficult to imagine what becomes of them all. These *Kentias* as indoor plants enjoy, I should say, at the present time a popularity only second to that universal favourite, the *Aspidistra*, which will not only exist, but actually thrive even in some of the most densely populated districts of London.—H. P.

**Forced Azalea mollis.**—This *Azalea* is so readily forced prematurely into bloom, that vast numbers are every year so treated, and during the autumn specially prepared plants bristling with flower buds are sent here from the Continent in large quantities. One very important point in connection with these *Azaleas*, and one that is too often overlooked, is that no time whatever should be lost in potting those that are needed for forcing, as the flowers on established plants retain their beauty for a much longer period than those produced by plants that are just potted and taken into the forcing house. This same remark will apply to all shrubs intended for forcing, but in few of them is the difference between established and non-established plants so pronounced as it is in this *Azalea*. In the case of those that are just potted, the blooms, generally speaking, open readily enough, but many of them soon drop; whereas the others remain a much longer time in perfection. Hence some prefer to keep these *Azaleas* intended for early flowering altogether in pots, and if a reasonable amount of attention is given them when out of bloom this arrangement will prove satisfactory. The leaves produced under glass are very delicate; hence the plants should be protected after their beauty is over until the season is sufficiently advanced to turn them out of doors. They may be plunged outside, when the principal point to be observed is to see that they do not suffer from want of water during the summer. After being forced for a season or two it will be found that as they make their growth earlier than those in the open ground their buds are sooner formed; hence early forcing is an easy matter. This feature is especially noticeable in

the case of other *Azaleas*, viz., the different varieties of the Indian section, and also in the little purple-flowered *A. amona*, which can easily be had in bloom before Christmas.—T.

#### THE WEATHER OF 1893 AND ITS EFFECTS ON THE GARDEN.\*

It will be most convenient to take the twelve months from November 1, 1892, to November 1, 1893, and a short record of the weather of each month will help us to gauge the weather of the year accurately. You will remember that the autumn of 1892 was fairly mild. In November there were five days on which the thermometer was below 32°, but the frosts were very slight. In December there were sixteen such days, but the frosts were very slight, so that the mean minimum for the whole month was only 32°, yet in the last week the frosts were severe, and on the 27th the extreme minimum of the year was reached, the thermometer going down to 17°. From that time for nearly three weeks there were almost continual frosts, and there were fourteen days of frost in January, with little wind and almost no snow. The rainfall of January was a little over 2 inches, and at the end of the month the thermometer was up to 52°. In February there were four days of slight frost, but there was over 3 inches of rain, and the thermometer reached 57°, and the month might be called almost favourable throughout. Then began the bright fine weather which lasted so long. March was fair all through with slight frosts on three days, with the thermometer reaching 65° and only four-tenths of an inch of rain, though rain was recorded on eight days. In April there were two slight frosts—the last of the season; the month was bright all through, the thermometer reaching 79°, and the rainfall only .06 inch, which fell in one day. May was almost equally fine, but not quite; the thermometer reached 77°, and there was a rainfall of 1.7 inches, spread over six days. June was a splendid month, though rain was recorded on eleven days; the thermometer reached 87°, and there was 1 inch of rain. In July there were a few wet days in the middle of the month, and rain altogether on fifteen days, making a rainfall of 4.3 inches, but on the whole it was a fine month with the thermometer reaching 83°. August also was a beautiful month, with 1.7 inches of rain spread over ten days, and the thermometer reaching 86°. September was equally fine, with 1.4 inches of rain spread over fourteen days, the thermometer reaching 77°. In October the weather began to change; it was on the whole a bright month, the thermometer reaching 69°, but there were 3.4 inches of rain, much needed, and on the two last days of the month there were frosts, and the glory of the garden was at an end for the year. The outcome of the year was this: Nearly seven months of bright sunny weather with very slight intervals of rain; a warm, but not an oppressive summer, with very little dew at night and almost no thunderstorms, and bright blue skies and clear atmosphere throughout. The only summer with which we can at all compare it was the summer of the Jubilee year, but that was in many respects very different. In that year there were three beautiful months of true summer, with very little rain; but it did not begin till the middle of June, and was preceded by a dull and wet spring, and that entirely altered the condi-

\* Portion of a paper read by the Rev. Canon Ellacombe, M.A., December 13, 1893, and taken from the published transactions of the Bath Natural History and Antiquarian Club.

tions, and so produced very different effects in the garden. The effects of the long summer in gardens this year were very remarkable, and in speaking of them I shall confine myself as much as possible to my own garden, and so speaking from personal observations shall be able to speak with more certainty.

The results were not altogether good, and it will be better to clear away first the bad side of the account. It has been a most disastrous year to all newly-planted things, and especially to newly-planted trees and shrubs. Many of them promised well for a time, but they could not stand the prolonged drought before they had got a good grip of the ground to enable them to draw their necessary supplies from the soil. For many plants, but especially for newly-planted ones, no amount of watering will supply what is wanted, and that is a moist atmosphere, especially at night. It was also a very disastrous year to plants which had been long established, but had been weakened by previous bad seasons, and were straggling back into strong life. For you will remember that the two previous winters had been very severe; and when you think of the hard frosts of December and January last, it is easy to understand that the constitutions of many plants had been sorely tried. Still many were not killed, and would have been able to make a successful struggle for life if there had been a mild and dripping spring; but they could not fight against the long continuance of bright suns and a dry atmosphere, and many of them died. That, then, was one item on the wrong side of the account; another was the great abundance and luxuriance of the weeds. The abundance cannot altogether be put down to the bright summer; it arose from the wet autumns of the two previous years, when the destruction of the weeds was almost an impossibility. In that way they had become well established, and then they seemed to revel in the bright sunshine of this year. I will name two particularly. I never saw Dandelions so abundant or so magnificent. I very much admire the Dandelion; in leaf, flower and seed it is one of the most beautiful plants I know, and I often wish it was not such a weed that I might grow it as one of our most brilliant flowers. This year it surpassed itself in brilliancy, and I often stopped to admire the size and depth of colour of the flowers in the hedgerows, and I was not, and indeed never have been, surprised at the praises it has won from some of our best poets, such as Tennyson and Jean Ingelow. The bright sun and still air also produced the beautiful heads of seed in great perfection, and, I am afraid, in too great abundance; and many of you will remember the grand specimens that we gathered in the churchyard of Malmesbury Abbey of its near relation, the wild Salsify. The other weed that was produced this year as abundantly, and even more unpleasantly, was Grass. It is quite remarkable how our flower beds have become almost covered with strong plants of Grass. I am sure that in my own garden there are several borders which would by this time have been quite covered if let alone. This is easily explained. There has been exceeding little lawn-mowing this year. The lawns, like the fields, produced no growing Grass for many weeks, but on the lawns, as in the fields, the Grasses, though very dwarf, went to seed, and the seed was scattered on the borders, which were well warmed and ready to receive them, and there they soon germinated, and produced abundance of plants. The same thing occurred with the large Grasses, the Bamboos, of which I grow several species. They made no growth at all during the hot weather, but as soon as

the drought was over they sent up vigorous shoots, but too late to reach their full growth. I should not have been surprised if some of them had flowered, but I am glad to say they did not, for when a Bamboo flowers it dies.

So much, then, for the bad side of the record; now for the other side. Surely it was a summer of prolonged delight; it was something to record and remember that for six months we could be in our gardens under a cloudless sky almost every day and all day long. That is the general aspect of the summer; but there are many particulars well worth noting, and first we note the flowers. Flowers of all sorts, with some few exceptions, have been most abundant. The one great exception was with the Lilies, which in my garden were dwarf and stunted and very poor in flower. But after making that exception and a very few others, think only what the Roses were; they were in masses, and though the hot sun faded them sooner than usual, they seemed to come again and again. Not only was this the case with the Hybrid Perpetuals, but with the summer Roses as well, and even with the spring Roses, for the Banksian Roses, both white and yellow, were in good flower in October, so that I am sure I could pick Roses from March till the frosts came at the end of October. But there were many flowers which I saw this year almost for the first time. I may mention these few. The *Eulalia zebrina*, which I never saw in flower before out of Devonshire; the *Osmanthus ilicifolius*, the *Asparagus verticillatus* and *A. acutifolius*, the grand *Hibiscus grandiflorus* from the Southern United States, which in former years did not produce even its buds till October and never came to perfection, but this year produced both flowers and seeds; and the Japanese *Bignonia* or *Tecoma grandiflora*, which I never saw in flower out of doors till this year, though it has often formed buds. From these few flowers I pass to

#### THE FRUITS,

meaning by fruits all seed vessels. To me the most interesting was the Japanese Orange (*Citrus trifoliata*). I have had a few small fruit on my tree in previous years, but they did not ripen. This year the tree was covered with blossoms in the spring, and as we had no late frosts I had plenty of beautiful fruit, which fully ripened and produced good seeds. The *Catalpa* had an abundance of fruit like long French Beans; this also fruited in the Jubilee year. The *Cassia marilandica* produced abundance of fruit and good seeds for the first time, which was also the case with *Phygelius capensis*, *Caryopteris mastacanthus*, *Arabis spinosa*, very elegant in fruit, like a delicate Ivy to which it is closely allied; the common Box tree, *Magnolia Lennei* with brilliant scarlet berries, and the fine *Asparagus verticillatus*. Outside my own garden I was pleased to see in the botanic garden in the Victoria Park the curious fruit of the Chinese *Xanthoceras sorbifolia* and the very pretty berries of the *Clerodendron trichotomum*. I have both these in my garden, and I believe older plants than those in the park, but I have never had fruit on them. And it is rather curious to note trees that have not fruited this year. There are no Holly berries, and very few berries on the Thorn trees. I have had no fruit on the Japanese *Diospyros*, or on the Christ's Thorn, though I have had them in other years not so favourable; nor have I had fruit on the *Koelreuteria*, which was covered with its golden pods in the Jubilee year; and Pomegranates in Bath, though they have formed their fruit, have not ripened them. But it is quite certain that this

non-fruited arose not from the peculiarities of this year, but from the weather of last year and perhaps even the year before. The autumnal tints were wonderfully good, and that must chiefly be put down to the bright summer, but partly also to the absence of early autumnal frosts. The late Miss Marianne North told me that of all trees she knew—and she had seen trees in all parts of the world—none could compare in beauty of autumnal tints with the *Salisburia*; but I never realised the truth of this till this year. I have a fine specimen on my lawn, and the autumnal tints came on gradually, a lovely pale gold colour, beginning with the lower branches and slowly spreading to the top, and lasting in their beauty a long time. The autumnal colour of the Tulip Tree is almost as beautiful, but with this curious difference: As long as the leaves are on the trees they are of a fine golden colour, but as soon as they fall they at once become of a dull ugly brown; whereas the leaves of *Salisburia* retain their colour long after they have fallen, and form a golden carpet underneath the tree until they are swept away. I grow a good many species of Vine, and they all showed a wonderful wealth of colour, though their near relatives, the *Ampelopsids*, were not by any means so brilliant as I have often seen them, and the tints of the *Parrotia* were very poor.\* And in connection with the autumnal appearance of the garden, it is worth noting that many people thought that we should have no autumn flowers on account of the early flowering of most of the plants, but the alarm was needless. The gardens this autumn were wonderfully gay; mine certainly was. Most of this, no doubt, was owing to the summer belders, which this year had in many gardens an increased value; but leaving them out of the question, and without entering into details, I can say that my garden in September and October was bright and gay. I rather expected to see an abnormal growth of spring flowers, but it really was very little more than in ordinary years. There were a few Primroses, as there always are; *Triteleia* showed a few flowers, and some of the *Narcissi* are showing their leaves well above ground; but, speaking generally, things are not too forward, but are, in gardener's language, in their right place. But I have one remarkable exception to this. I have had for many years a good plant of *Mandragora autumnalis* from S. Italy and Greece. When I first had it it flowered in the autumn, its normal time of blooming, but year by year it altered its time, and for several years past it has always flowered in the spring. This year—I suppose it thought it was again in the south—it sent up its curious leaves at the end of September, like a gigantic green star lying flat on the ground, and its beautiful flowers have been in great luxuriance all through October and November, and are still in their beauty (Dec. 16).

There are two accidental curiosities which must be entirely put down to the hot summer. One is the reappearance of long-lost plants. I have two such that are worth mentioning. I have good seedlings, not very near together, of some *Cytisus*, now healthy young plants, and yet I cannot call to mind ever having had a *Cytisus* that would produce such seedlings. The other case is much more curious. Many years ago, perhaps twenty or more, I used to grow the pretty little Cape plant, *Bulbine annua*. I am sure it is at least ten or twelve years since I have seen a plant in my garden;

\* Since writing this, the first volume of the "Index Kewensis" has been published, and in it *Ampelopsis* disappears as a genus, and all the species are placed under *Vitis*.

but this year they are in abundance and in many parts of the garden. And what adds to the curiosity is that they have come up in the same way in a friend's garden in the Isle of Wight, and he also cannot call to mind when he last saw the plant in his garden, but he is sure it is many years ago. The other accidental curiosity I would mention is the effect of the summer on our store fruit. Apples are keeping very badly, and in most cases ripened prematurely. Pears and Grapes, too, are ripening badly, and keeping badly. The greengrocers tell me it is the same with Chestnuts, and the further result is that the cider of this year will not keep, and housekeepers are mourning over the premature spoiling of their jams by mould. I suppose in the case of our own fruit, especially Apples, the sugar has been formed too rapidly and fermentation has set in, and this may help us to understand why it is that Apples do so much better in temperate regions than in hot climates. The fruit to be good must mature slowly. But this is only a guess. I do not profess to know all the mysteries of an Apple, or I might be able to explain how it is that the Apple is the hardest fruit tree known, ripening its fruit as far as 64° N.; yet Apple blossoms are more tender than those of the Apricot and Peach.

Leaving the garden, I should like to mention one memorable result of the fine summer. If it has been a great delight to the healthy and strong, it has been an untold delight to the weakly and invalid, and in many cases a prolonging of life and even a renewal of strength. In my own parish I have a remarkable proof of this. The ecclesiastical parish of Bitton has a population of 1200, and in the thirteen months from November 1, 1892, to December 1, 1893, there have been only three deaths, and of those three one was a child of a few weeks, sickly from its birth; another was an older child, who died from the effects of rheumatic fever, but whose life was certainly prolonged for at least three months, and happily prolonged on account of the bright, sunny weather; the third only was a man of full age. When you remember that 17 in 1000 in a year marks a healthy area, you will see something of the effect of a bright summer in reducing even that to 3 in 1200 in thirteen months.

The interesting question now remains, What will be the effect of the long hot summer on the present winter and on the gardens next year? I do not pretend to be a weather prophet, but I do not suppose that the weather that is past has very much effect on the weather to come, yet I am very hopeful that this winter will neither be long nor severe. It is very true that we have had severe frosts, and several of them rather earlier than usual; but an early winter is very seldom a severe or prolonged winter, and the late Sir Robert Christison, a very accurate observer, gave it as his experience for forty years that sharp frost late in October and early in November had been always followed by mild winters.\*

I have little faith in weather cycles, but I have great faith in weather averages, and it would be against all experience to have four severe winters in succession. I call that a severe winter for the garden when there is much

\* A period of from four to seven days of continuous hard frosts in the last week of October or first week in November. In the course of forty years I have not met with one exception to the rule that the frost then ceases and the winter continues open as far on through the winter as the last week of January. My observation does not carry me further.—"Life of Sir Robert Christison," vol. ii, p. 127.

skating, for skating requires a continuous frost and very little snow; and it is a continued frost that works mischief in the garden, especially if there are high winds and no snow. I am sure that a fortnight of cold weather with the thermometer at 25° is more destructive to plant life than two or three nights with the thermometer at 15° or even 10°. Certainly it is so if the ground is fortunately covered with snow during the lower temperature. But all this is literally *in nubibus*, and there we must leave it; but whether the winter is severe or not, it is quite certain that the long, hot summer has added much vital strength to all plants. There was during the autumn a formation in many cases of sappy shoots, which will probably be cut off, even if the winter is mild; but the main life of the plant will be safe, and from all present appearances next year will be a good year for flowers and fruit. We can gather that from the few which show the promise of next year, such as the *Pyrus japonica* and the early *Magnolias*, which are full of flower-buds, the *Hazels*, which are covered with catkins, and the *Pears* and *Peaches*, which are well provided with plump fruit-buds. And I should expect nearly all bulbous plants to flower well next year, for most bulbs rejoice in a good roasting when dormant, and that they have had this year.

And so I bring my paper to a close. Much might be said on the agricultural aspects of the year, but that is outside the limits of this paper. Much also of interest might be said on the effects of the summer on animals, birds, and insects, and some of that I hope will be told us by some other member of the club more competent to do so than I am. My work was limited to the weather and the garden, and on these two points there can be but one conclusion. The year has been indeed an *annus mirabilis*, a year which our children and grand-children will look back to, and when they are grumbling, as they certainly will grumble, at the bad weather of their own day, they will speak with regret of the lovely old-fashioned summer they remember when they were young—a year to be remembered and to be thankful for.

## SOCIETIES AND EXHIBITIONS.

### THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

#### ANNUAL MEETING.

THE above took place at Simpson's, 101, Strand, on January 17, Mr. H. J. Veitch taking the chair at three o'clock. It was most gratifying to note that continued progress is being made by this old-established and most deserving charity, by which untold benefits have been conferred upon gardeners or their widows (using the definition of gardener in the most comprehensive manner). The increase in the numbers of subscribers during the past year is not large, it is true, but to report any increase at all is most satisfactory at the present time, when many such institutions have to deplore a decreased income. This speaks well for the management, which is not conducted upon any narrow-minded basis, but upon a broad and enlightened view of the whole aspect of the situation. It is surprising that so few gardeners become either annual subscribers or life members. In neglecting this they are certainly standing in their own light. Such matters must not be looked upon in any selfish mood. Some may think that they will never need any assistance from its funds. If so, this is an indication that they have the means at their disposal to assist their more unfortunate brethren, and they ought to render what help they can. Many who have taken this selfish

view have thought they would never require the pension, yet there are such now on the pension list, whilst others are endeavouring to obtain election, but thus far some of these have failed. Even if a gardener should never need the pension, he ought, if he looked at the subject in the proper light, be only too glad to render help to others, not only by his monetary assistance, but by the privilege accorded him in voting for the election of deserving candidates.

It is most satisfactory to know that the last anniversary festival, presided over by Sir Julian Goldsmid, Bart., was a great success. Another very noteworthy advance has been made in the formation of auxiliaries in important centres. Three of these have been started, viz., at Bristol for Bristol and Bath, at Birmingham and at Wolverhampton. This new departure has proved most encouraging, and will be still further extended at other centres. During the past year fifteen pensioners have passed away. The committee, therefore, decided to recommend the addition of fourteen pensioners to those now on the books, eight of whom were elected without the expense and trouble of a contested election, they having fulfilled the conditions of rule iii., 5, to which important proviso attention should be directed. The remaining six were elected on the 17th inst., and the names of the successful candidates given in our last issue. It was with much regret that the committee felt themselves unable to assist a larger number of candidates, the more so as the list of those seeking election is the largest on record in the history of the institution. A perusal of the voting papers last issued will give full particulars of these unsuccessful candidates. With such a long array of applications before them, the committee appeal very earnestly for more support and increased efforts on the part of present subscribers. They specially plead with those for whose benefit the institution was founded to do all they can in urging its claims upon those with whom they come into contact and who are interested in horticultural pursuits. In order to increase the resources of the institution, the trustees, with the full sanction of the committee, decided to sell out the sum of £20,000 2½ Consols and re-invest the same amount in guaranteed securities bearing a higher rate of interest. They have therefore taken up the above amount in London and North-Western Railway and Midland Railway 3 per cent. Debentures, Great India Peninsula 5 per cent. Guaranteed Stock, and Manchester Corporation 3 per cent. Stock. This alone will give an increased income from dividends of about £50 a year. The treasurer of the institution, Mr. Harry J. Veitch, was unanimously re-elected to that important office, and most cordially thanked for his indefatigable efforts to further its interests. The auxiliaries, it should be noted, owe their greatest success to his personal attendance in advocating the benefits of the institution. Mr. G. J. Ingram was re-elected secretary and heartily thanked for past services. During the past year Mr. John Lee, who had for over fifty years taken the warmest interest in the institution, having been for many years the chairman of committee, resigned this important post. In accepting his resignation, the committee desire to place on record the valuable services Mr. Lee has rendered the institution in so many ways. Sir Alexander Arbuthnot, who takes a warm interest in horticulture, was approached, and he very kindly consented to fill the post of chairman in place of Mr. Lee. The annual friendly supper of the supporters of the institution took place at the close of the election, when Mr. George Dickson, of Chester, presided. He urgently appealed to all present to do their utmost in making greater advances in the immediate future, and thus add to the benefits conferred.

**National Chrysanthemum Society.**—A meeting of the general committee of this society was held at Anderton's Hotel, Fleet Street, on Monday last, when Mr. R. Ballantine occupied the chair. The business of the evening was almost

entirely of a purely routine nature in preparation for the annual general meeting of the members on the 25th prox. It was announced that the society's new publication—"The Chrysanthemum Year-Book"—was ready for distribution, and that the demand for it was already being felt. New members were elected, among whom were two foreign members, M. Crozy, of Lyons, and M. Ferdinand Cayeux. The secretary reported that during the year 1894 the following additions had been made: Fifteen affiliated societies, eleven Fellows, and 130 ordinary members. The report of the schedule sub-committee recommending the judges at the society's shows for the season of 1895 was presented.

**Royal Botanic Society of Manchester.**—The council of the above society has resolved to hold a great exhibition of Lilies in the gardens at Old Trafford, to open on the first Monday in August next (Bank Holiday). This being the first special exhibition devoted to the Lily, it is expected that much interest will be excited. It is requested that all interested in this Lily show will communicate with Mr. Bruce Findlay, Royal Botanic Gardens, Manchester.

## NOTES OF THE WEEK.

**Lily of the Valley.**—A charming mass of the Lily of the Valley has been sent us from Mr. Leeton, the Nurseries, Putney Park Lane, Putney, S.W. The plants are tall and most graceful, bearing fine foliage and spikes.

**Bulbocodium vernum** is fully a fortnight earlier in bloom this year than last. It generally is one of the first of the hardy bulbs to come into flower. At this season (when planted in clumps) the purple flowers are very conspicuous, two or three blooms coming from each bulb. It does not require any special treatment. Plant the bulbs during the autumn in a sunny position and let them remain undisturbed for three or four years.

J. W. H., *Warristor*.

**Olearia Haasti.**—For some years I have grown this in large quantities in one of the most elevated positions on the north-east coast. It is quite at home. No shrub here makes so much wood in a year and it never fails to flower freely. I have tried other species of *Olearia*, but none of them will succeed except *macradonta*, which does fairly well. I find *O. Haasti* strikes very readily from cuttings put in at any time during the summer months.—Geo. JOHNSON, *The Gardens, Harriethfield, Scarborough*.

**New plants in France.**—M. J. Sallier fils, Nemilly, France, sends us the following: "I had some fruit of the *Casuarina sumatrana*, and I have sent you a specimen by post, thinking that you would like to see a cone which is so rarely met with in cultivation, and the structure of which is so interesting for its uncommon regularity. As regards new plants, I am sending out in the spring *Rottlera homosa*, a very curious member of the Gesneria family; a yellow-flowered *Myosotis*, M. Traversi (to lovers of these plants a yellow-flowered *Myosotis* is an abomination); and *Euphorbia Fournieri*, a curious plant resembling a *Cereus* with the addition of broad leaves."

**Anemone japonica Honorine Jobert.**—When in the neighbourhood of Belfast in September last I saw a very fine lot of this beautiful autumn-flowering plant in the gardens of Mr. Victor Coates, Rathmore. The plants, which formed the back row in a mixed border in the kitchen garden, were about 4 feet high, nearly as much through, and a perfect mass of bloom. The soil in which they grew was of a clayey nature, and evidently suited them. Planted in this way or in beds the effect is much better than solitary specimens growing at wide intervals in the herbaceous border.—C. R., *Clayton West*.

**Protecting fruit at flower shows.**—When at Newtownards show last August I observed

how carefully the exhibits of fruit, vegetables, and farm produce were protected. As soon as the fruit was judged, a light wooden framework covered with wire netting was placed over it, thus effectually preventing people handling it. The vegetables and farm produce were protected by an upright framework covered with netting, a path being left between the stages and the protectors for the judges to inspect the exhibits. The above system, especially in regard to fruit, might well be adopted at some of the large exhibitions in this country. We should not then hear so many complaints about pilfering.—C. R., *Clayton West*.

**Calanthe bella.**—This charming hybrid Calanthe is now making a very brilliant display in the Victoria and Paradise Nurseries, Upper Holloway, and is useful where cut flowers are in demand. It was raised from *C. Turneri* and *C. Veitchi*, and produces long arching racemes of flowers, which are of a delicate light rose with a camine blotch at the base of the lip. It belongs to the vestita section, and should be given similar treatment to that group.

**Mistletoe.**—I had always understood that the growth of this parasite upon a tree was decidedly pernicious to the host, and there was a report a year or two ago that the French Government had issued an edict that all orchards were to be cleared of Mistletoe on this account, but I see that Mr. Burrell (p. 18) does not take this view. In some parts of Somersetshire it grows—or did so a few years back—on the standard Apples in some old orchards in great profusion. I remember, while staying in that county, seeing a fine bush of it growing on an old *Acacia* tree (*Robinia*) in a rectory garden. I have found it very easy to propagate, splitting the bark of an Apple tree and inserting a seed rarely failing to produce a plant; while four out of five seeds that I merely rubbed on to the bark on the underside of a branch germinated, though more slowly.—S. W. F.

**Lycaste plana and variety.**—This species is useful for winter flowering. It was originally discovered many years ago, and introduced in a living state into this country by the Messrs. Loddiges, of Hackney, about fifty years ago. The flowers, which are borne on scapes about 6 inches or more high, have greenish sepals shaded with brown; the petals white, reflexed and with a crimson blotch in the centre, the small lip being also white, spotted with rosy camine on the front portion. It should be grown at the warmest end of the Odontoglossum house or in a temperature intermediate between that for those plants and the Cattleyas. The variety *L. plana Measurciana* is a rare plant, similar to the typical form, but having olive-brown sepals with light green points, the white petals and lip densely spotted with purplish camine. A fine plant of this is now in flower in the nurseries of Messrs B. S. Williams and Son, of Holloway.

**Lycoris aurea** appears to be a very shy-flowering plant, and possibly the reason for several specimens having come into bloom last year is due to the exceptional heat of 1893 having been favourable to the ripening of the bulbs. Mr. Wallace gives some usual information respecting these bulbs, and suggests that they require warm house treatment. For bulbs imported from Hong Kong doubtless this would apply, but in the case of bulbs from a colder climate, different treatment might be necessary. Some eleven years ago I received some bulbs from the Foochoo hills. The climate was described as very cold in winter, and the soil in which they grew as stones and gravel. These bulbs have flowered but once since their arrival and have been subjected to various kinds of treatment—from hot to cold, from poor soil to rich. Under all the conditions they have grown well and multiplied, but have only flowered once, and that in an intermediate house. One bulb which I gave away a year ago flowered last October, having been grown in a cool frame. Any information on the treatment of these interesting plants would be valuable, as they are a beautiful addition to our gardens, and could they be in-

duced to flower as readily as they increase, they would soon become popular.—BEATRICE DUNCOMBE, *North Deighton Manor, Wetherby*.

**Hardy Cyclamens.**—What beautiful and interesting plants these are. After the snow and frost of the last few days, Cyclamen soon is now commencing to bloom very freely on the shady border, the deep red or crimson flowers, appearing through a carpet of deep green leaves which adds to their beauty, being very attractive at this time of the year. Close to the above are several plants of *C. Atkinsi*, which is also sending up a few white flowers shaded with pink; the petals finely serrated, with a deep maroon blotch at the base of each petal. I find the flowers very useful for small vases, and with a little attention they will keep fresh for eight or ten days. Hardy Cyclamens succeed best when planted on a moist, shady border, in some good loam, peat and sand. They seed very freely, and if the seed be sown as soon as ripe in well-drained pans and not allowed to get dry, it will soon germinate. The seedlings should be ready for planting out in about two years. The autumn-flowering kinds—*C. hederifolium* and the variety *album*—should also be included. The leaves of these autumn kinds are beautifully marked, and after the flowers have disappeared the foliage remains beautiful throughout the winter months.—J. W. H., *Worcester*.

**Bulb boxes.**—Can any reader of THE GARDEN kindly tell me of what wood most of the boxes sent here from Japan containing Lily bulbs are made? It is coarse, the grain runs in various directions, the knots are often very large, and it is evidently that of a conifer—I think perhaps *Cryptomeria japonica*—H. P.

**The weather in West Herts.**—A week of very changeable weather as regards temperature. Both the days and nights remained mild until January 22, when a change to colder conditions suddenly took place. On January 20 the highest reading in the shade was 49°, making this the warmest day of the month as yet, but on January 22 the temperature at no time exceeded 35°. On the following night a thermometer exposed on the surface of the snow showed 23° of frost, which is the lowest reading registered by this instrument during the present winter. The extreme cold lasted but a short time, the lowest point being reached at about ten p.m., the temperature rising rapidly immediately afterwards. At 1 foot deep the soil is now 3° above freezing, or about the average temperature for the previous nine Januaries. Rain or snow has fallen on each of the last twelve days, the total measurement being nearly 2½ inches. Twice during this period the ground has been covered with snow: on January 12 to the depth of 3½ inches, and on January 22 to the depth of 2½ inches, but on both occasions it soon melted. Several winter Aconites in my garden were ready to open before the end of the past year, but, owing to the frozen state of the ground and the dull weather, there was not an expanded flower to be seen until January 20. This is four days earlier than its average date of flowering in the previous six years, but three days later than in 1894.—E. M., *Berkhamsted*.

**Covent Garden Market.**—At Bow Street on January 22 Thomas Frobeck, Charles Champion, William Eames, Henry Lewis, jun., John Grover, William Grove, and Arthur Sole, salesmen, occupying shops in James Street, Covent Garden, appeared before Mr. Lushington, to adjourned summonses charging them with causing an obstruction and inconveniencing the public by allowing vegetables, &c., to stand in the roadway opposite their places of business for a longer time than was necessary for loading or unloading. The prosecution was undertaken on behalf of the Chief Commissioner of Police. Mr. Muir, for the defence, argued that the present practice in James Street had been continued for at least 100 years. This case arose out of a quarrel between the outside and inside men at Covent Garden Market. The inside men had to pay toll to the Duke of Bedford, and they

objected to outside men doing business without paying tolls. There had not been any inconvenience to the public. Several of the defendants were then called to show that the obstruction was not so great as alleged, and that the practice of placing goods on the side of the roadway had been allowed for many years. Mr. Taylor, a vegetable salesman in James Street, said that some years ago he saw Sir Charles Warren, the then Chief Commissioner of Police, with regard to alleged obstructions in that thoroughfare. Sir Charles agreed that the shopkeepers should not be interfered with if their goods were removed from the roadway before 9 o'clock in the morning. Mr. Lushington said it was perfectly clear that any arrangement with regard to James Street entered into by Sir Charles Warren would not in any sense be binding on the Chief Commissioner of the present day. Each defendant would have to pay a fine of 20s. and 10s. costs. Mr. Lushington added that in future cases the full penalty would be imposed.

#### RAINFALL IN 1894. INVERIE GARDENS, INVERNESS-SHIRE.

For year 1894.	Average temperatures.				Total rainfall, inches.	Most rain in one day, inches.	Number of days no rain fell
	Max.	Min.	Wet bulb	Dry bulb			
January	41.15	32.19	38.94	39.2	10.17	1.88	7

Total rainfall for the year . . . . . 85.71

—J. HERRIS.

#### TRADE NOTE.

**An effective vaporiser.**—I have tried a great many of the various insecticides that have been brought before the public of late years, and they have by no means given universal satisfaction, some failing to make a clearance of insect pests, or perhaps injuring the plants, while others require a good deal of time and attention. It is now generally admitted that nicotine in the form of vapour is more effective than tobacco smoke, and the best vaporiser I have tried is that known as the "X L all vaporising Fumigator," sold by Mr. G. H. Richards, Lambeth, S.E. It may be used without injury to flower or foliage. I have tried it on show Pelargoniums in flower, on tender Ferns and Orchids in bloom, none of which were in the least injured, while both aphides and thrips were destroyed. The smell afterwards is not in the least displeasing. The whole operation is very simple, the vaporising being effected by a small spirit lamp.—H. P.

#### BOOKS RECEIVED.

"Treatise on the Physiology of Plants." By Dr. Paul Sorauer. Translated by T. E. Weiss, Professor of Botany at the Owens College, Manchester. With 33 illustrations. Longmans, Green and Co., London and New York.

National Chrysanthemum Society's Year-book for 1895.

**Name of fruit.**—*Reader*.—Apple is Rymer.

**Name of plant.**—*Hamilton Leigh*.—A fairly good form, but should like to see a flower when the plant has become established.

**The Wild Garden:** or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers. Fourth edition, with wood engravings from drawings by Alfred Parsons, revised and enlarged. Long 8vo, limp cloth. Price 12s.; well bound in half morocco, 18s. Through all booksellers.

"This is an Art  
Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## TREES AND SHRUBS.

### TREES AND SHRUBS CERTIFICATED IN 1894.

THERE is no doubt that within the last few years hardy trees and shrubs have become more popular; hence greater numbers are shown at the meetings of the Royal Horticultural Society, and the list of those upon which first-class certificates or awards of merit have been bestowed shows a corresponding increase. Thus during the year 1894 no less than thirty-two, exclusive of Roses and Tree Peonies, have been so honoured, while in 1893 the number was only twenty-two, and in 1892 no more than ten.

A general opinion is that these certificates are given only to new plants, but this is by no means the case, as many well-known subjects are every year honoured in this way. The trees and shrubs certificated during 1894 are:—

**AMYGDALUS PERSICA MAGNIFLORA.**—This beautiful variety of the double-flowered Peach was shown on February 13 by Messrs. Veitch, when a first-class certificate was awarded it. The flowers are of a brilliant crimson colour. These double Peaches, especially those of such decided tints as this, are really charming, flowering as they do so early in the year when most subjects still wear their winter garb. They are often used for forcing, and no doubt this newer form from its richness of colouring will be much sought after for this purpose.

**LOROPETALUM CHINENSE** is a near ally of the Witch Hazels (*Hamamelis*), and, like them, the flowers are composed of four narrow strap-shaped petals, a good deal twisted, and of a creamy-white tint. In other respects it is very different from the *Hamamelis*, the foliage being oblong, pointed, and of a deep green. It is also evergreen in character. This *Loropetalum* is a native of China, from whence it was introduced in 1880, but it is at the present day very uncommon. A first-class certificate was awarded to it on March 13, the flowers apparently having been brought on under glass.

**AZALEA ALBICANS.**—This is the result of intercrossing the Chinese *A. mollis* with the North American *A. occidentalis*. The flowers, which are borne in bold trusses, are like those of a good form of *A. mollis*, their colour being white, slightly suffused with yellow, which is more pronounced on the upper segments. An award of merit was bestowed upon this on March 13.

**FORSYTHIA INTERMEDIA.**—Two *Forsythias*, *suspensa* and *viridissima*, have been grown in our gardens for years, and this form, *intermedia*, distributed by M. Lemoine, of Nancy, about six or seven years ago, was announced as a hybrid between the two first-named species. In general appearance *F. intermedia* is about mid-way between the two, but though it may not be superior or even equal to its parents as an early spring-flowering shrub, it will be always welcome. An award of merit was given this on March 27.

**RHODODENDRON PRINCESS WILLIAM OF WURTEMBERG.**—Little seems to be known concerning the origin of this *Rhododendron*, but it is certainly a very distinct and telling variety. As shown it is of a sturdy, compact style of growth, while the flowers are borne in large trusses. The colour of the flowers is white, densely spotted and barred with crimson—quite a distinct feature among hardy *Rhododendrons*. A first-class certificate was awarded to it on April 24.

**RHODODENDRON RHOMBICUM.**—This was formerly known under the generic name of *Azalea* and is a

decidedly pretty early-flowering shrub. In colour *R. rhombicum* is a good deal like the North American *Rhodora canadensis*, but it forms altogether a more compact and bolder growing bush, while the flowers are much larger and better shaped, added to which they are of a brighter tint of rosy purple than those of the *Rhodora*. *Rhododendron rhombicum* may be looked upon as the first of the hardy *Azaleas* to unfold its blossoms. It has been long known in this country, but except at Kew, from whence the specimens came that received an award of merit on April 24, it is very rarely met with. This *Rhododendron* is a native of Japan, and in the island of Nippon it is said to be plentiful.

**RHODODENDRON ROSY BELL.**—This is one of the many hybrids raised, I believe, by Messrs. Davies, of Ormskirk, to whom we are indebted for that beautiful early-flowering variety *præcox*, which has now become so popular. *R. Rosy Bell*, which evidently claims parentage from *R. ciliatum*, is a dwarf, compact-growing plant with dark green Myrtle-like foliage. The flowers, which are rather blunt in shape and widely expanded at the mouth, are each from 1½ inches to 2 inches in diameter, and in the bud state of a deep reddish pink colour, which after they open becomes much paler. The interior of the flower is of a delicate blush, almost white. The blooms, which are borne in clusters well above the foliage, are slightly drooping or arranged in a nearly horizontal manner, and a pretty effect is produced by the contrast in colour between the unopened buds and the expanded blossoms, as well as by the crisped edges of the petals. An award of merit was bestowed upon it on April 24.

**PYRUS SPECTABILIS MAGNIFICA.**—The Chinese Crab (*Pyrus spectabilis*) is well known as one of the most beautiful of our early-flowering trees, and this form when better known will no doubt be much sought after. The flowers are larger and bolder than those of the type, while they are also somewhat deeper in colour. It was given an award of merit on April 24.

**EXOCHORDA ALBERTI.**—This Turkestan species of *Exochorda*, which has been introduced through the Russian gardens, differs a good deal from the better-known *Exochorda grandiflora*. It is of a stiffer and more upright habit of growth, while the leaves are rather longer and of a deeper green. The individual blooms are a good deal in the way of those of *E. grandiflora*, but they are borne in an erect rather closely packed spike; whereas those of *E. grandiflora* are arranged in a far looser manner. *E. Alberti* received an award of merit on April 24.

**RHODODENDRON HIGH BEECH HYBRID.**—This was announced as a hybrid between *R. Fortunei* and *R. Mrs. C. Butler*. It is certainly a very pretty *Rhododendron* with salmon-pink blossoms, which are very sweetly scented.

**LILAC MME. LEMOINE.**—This is one of the many double-flowered Lilacs raised by M. Lemoine, of Nancy. It differs from those previously grown in the flowers being pure white, and on this account as well as the duplex character of its blossoms it will doubtless become popular.

**LILAC SOUVENIR DE LOUIS SPATH.**—This is by no means a novelty, but it is one of the best of the rich deep-coloured single varieties, and on that account received, as well as the variety *Mme. Lemoine* just mentioned, a first-class certificate on May 8.

**LILAC PYRAMIDALE.**—Another of Lemoine's double varieties with massive panicles of bloom, purple in the bud state, but bluish lilac when fully expanded. There are so many of these double Lilacs now, that it is difficult to see the difference between them.

**LILAC GEANT DES BATAILLES.**—This is by no means a novelty, but it is a good single-flowered form, purple in the bud state, changing on expansion to a kind of rosy lilac. These last two forms received awards of merit on May 8.

**PIERIS FORMOSA.**—This is a highly ornamental evergreen shrub, introduced from Nepal in 1881. It is, however, hardy only in the favoured districts of England and in Ireland. It forms a

large, bold-growing bush somewhat like an *Arbutus*. The flowers, which are borne in terminal branching panicles, are white, slightly tinged green. They are urn-shaped, and, in common with several of their allies, are of a thick wax-like texture. The genus *Pieris* is nearly allied to *Andromeda*. An award of merit was bestowed upon *Pieris formosa* on May 8, the specimens having been sent from Glasnevin.

**MAGNOLIA PÆNIFLORA.**—This is certainly one of the best flowering shrubs certificated during the year 1894. *M. parviflora* is a freely-branched species, clothed with broadly ovate leaves of a deep green tint and 3 inches to 4 inches long. The flowers, which are about 5 inches in diameter, are white, becoming slightly tinged after expansion, while a conspicuous feature is formed by the cluster of erimson stamens in the centre of the flower. For this *Magnolia* we are indebted to Messrs. Veitch.

**WISTARIA MULTIFLORA.**—Some fifteen years ago a deal of attention was directed to this *Wistaria*, it being at times spoken of as superior to the old and well-known *W. sinensis*. Among other qualities claimed for it was the fact that the flower racemes reached a length of 1 yard. Time has, however, proved that it is not so free-flowering as the old kind, and the flowers are much smaller and distributed at wider intervals on the stem, so that it is not nearly so showy as the typical *W. sinensis*. At the same time it is both pretty and interesting, and some racemes of it shown at the Temple show when it received an award of merit were about 30 inches long.

**RHODODENDRON SNOWFLAKE.**—A standard plant of this *Rhododendron* was very showy by reason of the profusion of its large white blossoms. The only colouring consisted of a few reddish dots on the interior of the upper part of the flower.

**RHODODENDRON DUKE OF YORK.**—A showy variety of a rosy-pink, with brown spots on the upper segments.

**RHODODENDRON DUCHESS OF YORK.**—Salmon-pink, margins flushed rosy-pink, upper petals spotted green. These last two varieties resulted from the intercrossing of *R. Fortunei* and the garden variety *Scipio*, and to both awards of merit were given.

**FAGUS ROTUNDFOLIA.**—This is a very distinct Beech, the leaves being less than 1 inch in diameter and of a very deep green tint. It is of a close, upright habit of growth, and presents altogether a very uncommon appearance. A first-class certificate was awarded to it on June 12.

**SYCAMORE, CRIMSON-FRUITED.**—The Sycamore is a somewhat varied subject, and in this particular form the fruits are of a bright crimson colour, which renders it very telling. It received an award of merit on June 12.

**RUBUS JAPONICUS TRICOLOR.**—This is a slender growing Bramble with very decided variation. The young stems and leaf petioles are of a bright rose colour, while the leaves, which vary from cordate to three-lobed, are variegated in different ways. Some of the leaves are marked with green and white in about equal proportions, while in many, the younger ones especially, the white predominates, and in addition to this the youngest leaves are suffused with pink. As shown, this *Rubus* at a little distance reminded me very much of *Vitis heterophylla variegata*. It received a first-class certificate on July 10.

**RUBUS PHENICOLASICS.**—Under the name of the great Japanese Wineberry this has attracted a good deal of attention within the last few years. It is a bold, strong-growing, Raspberry-like species, the leaves of which consist of three heart-shaped leaflets, dark green above and whitish underneath. The stems, and more particularly the young shoots, are densely clothed with long reddish hairs, thus imparting a very striking feature to the plant. In the winter when devoid of foliage this is especially noticeable. The fruits are a good deal in the way of small Raspberries, and red when ripe. It was introduced in 1877, but it is only within the last few years that any particular attention has been directed towards it

as a fruit-bearing subject. On August 14 it was awarded a first-class certificate.

**ACER PURPURASCENS NIZETTI.**—This is a form of the Sycamore with the undersides of the leaves purplish red, the upper part being green, blotched in an irregular manner with cream. The leaf-stalks are red. This is seen at its best in the spring soon after the leaves are expanded, but an award of merit was given it on September 25 at the Chi-wick conference.

**ALEX AQUIFOLIUM LAWSONIANA.**—This is a very pretty Holly, but by no means a novelty. The leaves, which are very sparingly furnished with prickles, are oval in shape and of an olive green towards the margins, the centre being blotched with yellow and bright green disposed in a very irregular manner.

**VERONICA CUPRESSOIDES.**—This is one of the curious Whipcord Veronics, the members of which to a casual observer bear a far greater amount of resemblance to a small-growing conifer, such as some of the Retinosporas, than they do to a Veronica. In these the leaves are limited to small scales closely adpressed to the stem, exactly as in many of the Coniferae. *V. cupressoides* is upright in growth, very much branched, and of a bright green tint.

**VERONICA SALICORNIOIDES.**—This is dwarfier and of a more spreading habit than the last, the colour being light green tinged with yellow.

**VERONICA LYCOPODIOIDES.**—This is a little dense growing species with tiny dark green leaves arranged in four rows. These three Veronics were awarded first-class certificates on September 25.

**VITIS COIGNETIE.**—This large-leaved Japanese Vine has attracted a good deal of attention within the last year or two, a question among others that has arisen being whether it is distinct from the many species now in cultivation. The gorgeous autumn display furnished by a large Vine at Knap Hill has been told over and over again, and it is by some regarded as *Vitis Coignetie*, but at the same time it appears somewhat different from Messrs. Veitch's specimens. At all events it will serve to direct attention to the great beauty of these large-leaved Vines, which will lend themselves to many bold arrangements. T.

**Abies pungens glauca.**—The type of this beautiful Fir is one of the very best of the American Spruces. This is an exceedingly well-marked glaucous form, in every respect most distinct. It has on several occasions been shown at important meetings during the past year or two, always being an attractive feature by reason of its silvery-grey shade of colour overlaid with a bluish tint. As a specimen plant for the pleasure grounds or for avenue planting it will undoubtedly be much sought after as it becomes better known. Compared with *A. nobilis glauca*, it is, in my opinion, much the superior plant, being of more regular outline and superior growth, whilst its glaucous tint is deeper. From notes taken I should consider that it will be found to thrive well upon somewhat light soils, provided there is sufficient moisture.—G. H. A.

**Sciadopitys verticillata.**—Like your correspondent "G." (p. 32), I am of opinion that the reason this beautiful conifer is not more often seen in a flourishing condition is that it is frequently planted in too dry a situation, and it also seems to dislike removal. A soil partially composed of vegetable matter, more especially thoroughly decayed leaf-mould, suits it well, and perhaps this is owing to the fact that such a compost retains moisture for a longer period than soils which consist of light sandy loam, which prevails in so many places. At Kew, where many conifers are by no means seen at their best, there is a specimen of the Umbrella Pine in a very thriving state. It is planted in a cool, moist, but at the same time by no means waterlogged spot and progresses in a very satisfactory manner. The deep rich green tint is very characteristic of this *Sciadopitys* when in a thriving state. In this country, however, its rate of progress is but slow, and it will take a very

long time to attain the height of 100 feet, which it is said to do in Japan. The Umbrella Pine was first introduced by Messrs. Veitch about thirty-five years ago, and it still forms a prominent feature at their Coombe Wood nursery. It seems to be quite proof against our English winters. Gordon speaks of several varieties being in cultivation in Japan, but, with the exception of one with variegated leaves, they do not appear to have reached this country, though among the specimens met with, individual differences, of course, occur. The variegated-leaved form which was introduced by Fortune with so many other variegated-foliaged subjects had yellow leaves interspersed with those of the normal tint, and sometimes the variegation extended over half of the leaf, the rest being green. This variegated variety was very generally met with about twenty-five to thirty years ago in the collections of choice variegated plants then so popular, but it now seems to have almost dropped out of cultivation. A great drawback was its liability to revert to the type.—T.

**Hedera maderiensis variegata.**—No doubt the majority of the readers of THE GARDEN have proved the great value of this Ivy for the open. But is its worth so fully or so abundantly realised in the greenhouse and conservatory, and particularly during the dull season of the year? What could be brighter at this time than some well-coloured examples around the roof supports in the greenhouse or similar structure? At any time it is one of the most ornamental, and where grown in a cool, or even cold house in winter it is doubly valuable. By reason of its attractive foliage some pot plants may be turned to good account for the embellishment of entrance halls, or even in parts of the mansion itself. Thus used they would relieve the monotonous greenery of Palms, Ficus and evergreen shrubs. Many years ago, prior to its distribution, I called at Messrs. Osborne's nursery at Fulham, and was shown a house filled with young plants almost 2 feet high. As there seen the house was as effective as if filled with flowering plants, save for the sameness. Plants of similar size, however, and well coloured should surely prove of great service to the gardener and floral decorator alike, especially when flowering plants in pots are scarce.—E. J.

#### JANUARY FLOWERING SHRUBS.

GIVEN fairly mild open weather during the month of January, there will be (especially if it has not been very sharp before that time) several of our hardy shrubs whose blossoms will tend to lighten a dull winter's day. A comparatively uncommon subject, but one that is rapidly making its way in popular favour, is the Japanese Witch Hazel (*Hamamelis arborea*), which, though it attains the dimensions of a small tree, will yet flower freely as a shrub. The peculiar starry blossoms of a yellow hue with which the leafless twigs are crowded furnish a striking and uncommon feature. The general appearance is well shown in THE GARDEN, June 13, 1891, where there is a coloured plate of *H. arborea*. A sharp frost will destroy the full expanded blossoms, but a few mild days cause others to open and take their place. In the event of January being a very cold month this *Hamamelis* will not, as a rule, bloom till February. *H. arborea* is the best of the Witch Hazels, there being a smaller growing species (*H. japonica*) with paler blossoms that flowers, as a rule, about a month later. In some seasons that variety of the Mezereon known as autumnalis, or grandiflora, will bloom well in the month of January, and at other times it is over by Christmas. Should the weather be mild, however, the earliest blossoms of the typical kind will by the end of the month be well advanced towards opening. The Laurustinus has been flowering grandly this season, and where not cut by recent frosts it occupies a prominent place among January flowering shrubs. *Berberis*, or *Mahonia japonica* often has its long spikes of lemon-

tinted blossoms expanded by the new year, and during the second month the golden flowers of its North American relative, *Berberis Aquifolium*, commence to open. This last is one of the most beautiful of all our flowering shrubs, but its merits in this respect are very apt to be overlooked because it is so common. Where protected by a wall we may note several other subjects, the first of which, the Winter Jasmine (*Jasminum nudiflorum*), has been long in flower, while the deliciously fragrant blossoms of *Chimonanthus fragrans* are now expanding. They are not showy, but their perfume is very pleasing, and if a few sprays are cut just as the buds are bursting, they will open beautifully in water and fill a room with their fragrance. The Japan Quince (*Cydonia japonica*) will on a sunny wall be opening its earliest blossoms, and a bright object this forms in the depth of winter. Where they can be spared, some sprays of these cut as above noted in the case of the *Chimonanthus* will be pretty objects indoors. As the season advances other shrubs will expand their blossoms, and following the above most closely, we have those two sweet-scented Honeysuckles with white flowers—*Lonicera fragrantissima* and *L. Standishi*, both of which need the protection of a wall, and the Cornelian Cherry (*Cornus mas*). In this the inflorescence assumes the shape of little tufts of bright yellow blossoms, and being thickly disposed on the twigs, they are, when nearly everything else is bare, very attractive. Of dwarf plants of a shrubby character we have the pretty little Winter Heath (*Erica carnea* or *herbacea*), whose bright-coloured blossoms form a very charming feature. The white variety is also very pretty, though less showy than the typical kind. This little Heath will continue to flower for months together, and much the same may be said of some of the other subjects above mentioned, especially the Japan Quince. H. P.

#### **Saxifraga cotyledon varieties for pots.**

As a pot plant for the conservatory and greenhouse very few members of this genus can surpass this species and its varieties. Of these latter the most beautiful perhaps is that known in gardens as *S. nepalensis*, a charming plant when seen in good condition, and producing its great rosettes of silvery leaves fully 15 inches across. In moist sandy soil I have seen them even larger than this, the huge pyramid of white blossom at the base reaching almost to the extreme of the leaves. Indeed, this appears a characteristic of this variety, which one does not often see. Another point of distinction is the graduated form of the pyramid from base to summit. Some of the finest examples of this I have ever seen were grown in the late Mr. Parker's nursery at Tooting many years ago. The flower-spike is from 18 inches to 20 inches high, forming a perfect pyramid. Another good kind is *S. pyramidalis*, which is much more frequently seen in cultivation. In this the rosettes are more clustered and the leaves more erect, shorter and blunter than in the preceding. This variety, in my experience, has not the branching habit of *S. nepalensis*, nor do the flower-spikes possess the perfect pyramidal form of that kind, the flower spike for the first 4 inches or so being usually bare, developing eventually into a somewhat taller and denser plume-like pyramid. It is quite easy to increase the type and *S. pyramidalis* by division, while *S. nepalensis* can be best increased by offsets, which are produced at the base of the flowering rosettes. The offsets make greater progress if dibbled out into sandy loam a few inches apart. When grown in pots these should always be freely drained, and in addition to the sandy loam—which should constitute the bulk of the soil—some broken brick or old mortar rubbish will be found beneficial. Always pot firmly and avoid over-much water at the root. The size of pot must be regulated by the plants. Quantities of medium-sized plants are grown for market in pots 6 inches across.—E. J.

ORCHARD AND FRUIT GARDEN.

GLOU MORCEAU PEAR.

THE demand for this well-known Pear has been keener than usual this season, as many varieties have been of poor flavour or have failed to keep. Glou Morceau is an exception with me this year, being now in daily use for dessert and of very good quality. The fruit from both wall and bush trees is alike excellent, and a variety that is of superior flavour and a sound keeper in a notoriously bad season is worthy of special notice. Few varieties are so certain in cropping both in cold and warm districts if on the right stock. When I was foreman at a well-known place in Staffordshire we had bush trees of Glou Morceau worked on the Quince that seldom failed to bear fair crops, in spite of a bleak district and a wretchedly cold soil. The trees were simply put on the level ground, staked, and good soil brought and placed over the roots, thus forming raised mounds, afterwards mulching annually with farmyard manure. Those who have to contend with cold soils might adopt the same plan, procuring trees worked on the Quince, as it is the most suitable stock for such soils. The roots keep near the surface in search of the food contained in the mulchings, and will not descend into the cold and poor soil lower down unless actually forced by poverty. On warmer and deeper soils Glou Morceau grows and produces heavy crops on the Pear stock. For the first few years it may grow rampantly, but if the shoots are allowed to remain their full length or nearly so, fruit buds will be formed the whole length, and the crop of fruit will effectively check any exuberance. This applies equally to wall or other trees out in the open, and is much to be preferred to root pruning. Many Pears are inferior in flavour if grown to a large size, but the finer Glou Morceau is, the better the quality in this neighbourhood, and those people who desire exceptionally large fruit have a good opportunity to secure them from wall trees by thinning them out while small to 6 or 8 inches apart each way and mulching with manure; also giving occasional soakings of liquid manure. Trees worked on the Quince are very grateful for these applications, deriving more benefit therefrom than trees on the Pear stock.

W. G. C.

**Apple Lane's Prince Albert.**—I quite agree with "E. M.'s" note (p. 36) as to canker not usually attacking this Apple. I have during the last week looked over eighty trees, which show no symptoms of disease. The tree that I alluded to (p. 23) was one of a lot of thirteen, all of different kinds, which were planted in heavy, damp, and partially shaded ground as an experiment, with a view to seeing which sorts stood the test best. Lane's Prince Albert has fared better than seven of the sorts and worse than five, the only one that is thoroughly satisfactory being Duchess of Oldenburg. The situation is exceptional, and would not be chosen except for experimental purposes, the bark of the trees becoming emerald-green every year and having to be cleansed with dressings every winter.—S. W. F.

**Digging round fruit trees.**—At page 24 "Y. A. H." condemns the practice of digging too near the stems of fruit trees on walls. I quite agree with his remarks, and would advise that the soil be simply pricked over, so as to break the hard crust caused by repeated treading. This is my plan, doing it at the beginning of the new year, afterwards sprinkling on a little artificial manure, and finally mulching with spent hot-bed material. By this means the surface roots are preserved, fed, and rapidly increased. I do not hold with the too common practice of mulching fruit

trees in autumn, especially on retentive soils and with strong green manure. This has a tendency to keep the surface raw and cold and to drive the roots in a downward direction. Spring mulching is far preferable.—J. C.

**Too many Apples.**—The Royal Horticultural Society would benefit the fruit-growing community of Great Britain if it would reduce the number of sorts of Apples which are now offered by nurserymen to the public, and establish on an authoritative basis those which are most likely to be remunerative to the planter. This is not difficult, as the members of the fruit committee assemble from various parts of the country. Supposing that the best part of the sale period for Apples lasts from July to the end of March, a

fruit. Many other kitchen Apples are equally good, and if these are mixed with dessert sorts, such as Cox's Orange, Mother, and other kinds, a very superior drink can be made, thus giving two chances of employing an abundant crop.—T. F. RIVERS, *Sawbridgeworth, Jan. 15.*—*Field.*

APPLES AND CANKER.

APPLE KING OF THE PIPPINS, mentioned by Mr. Wythes at p. 22, did remarkably well in poor soil with me some years ago, and it has been my best dessert Apple this year, as Cox's Orange Pippin has failed in different parts of the garden. I cannot understand the experience of "S. W. F." as to Apples being more liable to canker on the Paradise than on the Crab stock. He does not seem very positive, and probably has not given the matter much attention. I have proved again and again that the best way to prevent canker in Apple trees is to prepare the ground well by trenching it to a depth of 2 feet, less or more according to the nature of the soil. Very often 18 inches is as deep as it is possible to go, and whether the trees are grafted on the Crab or the Paradise stock they ought to be healthy, well-rooted trees to begin with. Many trees are neither healthy nor well rooted, and if such are planted in ground that has not had any preparation, the wonder would be that they did not canker.

In healthy, well-rooted trees grown in well-prepared soil I am confident that canker will not be likely to appear, except in the case of a very few varieties which are peculiarly liable to this disease. The only three I have had any trouble with have been Wellington, Cellini and Ribston Pippin. We can do without Cellini, and the way I have cured the disease on the others has simply been to lift the roots up nearer the surface, and instead of filling in all the old soil during this process I make up with fresh loam that has not been near the roots of Apple trees. Of course, this cure is applied as soon as it is seen that canker is present. Let anyone try this on certain trees and leave others cankered in the same way without interfering with the roots, and the result will be convincing. The reason why trees on the Paradise stock are not so liable to canker as those on the Crab is doubtless owing to the fact that the former have the greater tendency to root near the surface, and cultivators acting on this assumption spread the roots out well near the surface when planting them; moreover, the downward tendency of the roots is checked by mulching over the surface where the roots are with a slight dressing of manure during the summer months. All roots have a natural tendency to travel where they can get the best food. Surface roots push freely from the main stem of the Paradise stock quite up to the union of the graft with the scion, and the fine white roots may be seen pushing into the moist mulch even above the surface of the ground. This does not occur with the trees worked on the Crab stock; they are all to be found working deeper and deeper into the poor, damp, and oftentimes wet subsoil, a state of things which is sure to produce canker. I always advise planters when setting out their trees on the Paradise stock to plant quite up to the union

Part of a tree of Glou Morceau Pear.

period of nine months, three sorts of Apples per month, or even less, would be quite sufficient; but in any case the number of Apples may be reduced to thirty-six, allowing a surplus for the prejudices and possibly the practical experience of planters in many localities, who are certain to adhere to the knowledge gained from experience. It would not be difficult for the fruit committee to select those kinds which can be honestly recommended to the public. It does not seem to be generally known that all Apples of good quality will make good cider. It is not at all necessary to plant the so-called cider Apples. Probably these were originally chosen because they will bear any amount of rough usage. The Apple known as Rymer is a first-rate cider-making Apple—it is usually grown as a kitchen

of the stock with the scion. In this case roots are produced freely from the main stem up to the point of connection. I grow all mentioned by "S. W. F." at p. 23, with the exception of King of Tompkins County. Bismarck is a good bearer now that it has become established, but it is quite second-rate as regards cooking qualities. As the fruit is good looking it might do to sell, and might be purchased by those who did not exactly know what they were buying. Lane's Prince Albert is one of the very best, but the trees on the Paradise cannot get up amongst the others; the yearly weight of fruit they have to bear is enough to dwarf the trees into mere pigmies. I have planted some on the Crab stock, and probably this will throw more vigour into them.

J. DORGLAS.

#### DESSERT APPLES.

MANY of the Apples of recent introduction, although conspicuous for size and external beauty, certainly lack quality as compared with older varieties. This deficiency is more noticeable in the dessert varieties. Moreover, many of the newer kinds will not keep any time after they are ripe, while the cropping qualities and general constitution of the trees are not such as to warrant their being freely planted in any but the most favoured districts. The earliest Apple I know of is the White Juneating, which ripens about the end of June in the south and the first week in July in the garden here. It is below medium size and creamy white in colour, but I cannot say much for the flavour, it being rather too acid to be pleasant. It is, however, a most continuous cropper in any form, doing well with me as an espalier. The next to succeed it is Gladstone, but this Apple, although handsome when exposed to the sun, is very disappointing, and even when eaten from the tree is often mealy and flavourless. One tree of it is quite sufficient in any garden. Lady Sudeley, somewhat recently introduced, is perhaps the handsomest dessert Apple ripening in early autumn, but, like the foregoing, it will not keep long, although if eaten within a week after being gathered it is crisp, juicy and excellent. My only experience of it is in the horizontal cordon form, where it grows freely enough, but fruits shyly, and from what I learn from other sources I am afraid its culture will never become general. Perhaps, however, it may crop better further south than with me. In my opinion that showy little Apple Beauty of Bath will be the early dessert variety of the future. Not only has it symmetry, colour and very good flavour, but the fruit will remain firm and juicy after the majority of autumn Apples have become useless. The tree bears well in any form, hundreds having been planted in the bush form during the last two years, the fruit from espaliers being quite a picture. Worcester Pearmain was very popular for a year or two, but its treacherous character as a keeper was soon discovered, few market growers planting it now-a-days. Perhaps the most reliable dessert Apple, all points considered, is the old King of the Pippins. It does well in any district, and quickly grows into a large tree. No fault can be found with the flavour, while it will keep in saleable condition for several months. As a rule, too much praise is accorded Cox's Orange Pippin. This Apple is very particular as to soil and locality, is slow in coming into bearing, while the blossom is extremely tender. Its capricious character is proved by the fact that it is never seen in any quantity in the market. I have occasionally seen fair crops on light soils, and the flavour is of the finest. Ribston Pippin, esteemed by all for its rich aromatic flavour, seldom makes a large tree, as it usually falls a victim to canker in its worst form two or three years after being planted. The finest fruit is produced from espaliers grown in a sandy soil, but last year I saw a large standard growing in the orchard at Ossington Hall, twelve miles from here, apparently very old, but healthy and loaded with the largest fruit have ever seen of this variety. The situation

was high, though sheltered, and the soil well drained. Margil, a small Apple similar to Ribston in flavour, but superior in my opinion, is seldom met with now, its chief fault also being canker. If grown on a warm soil and lifted once or twice, say the second and fourth year after planting, this malady is not so likely to appear, the great point being to keep the roots near the surface. It should be worked on the Paradise stock. The only cure for canker is said by some to lie in lifting the trees and bringing old roots near the sun's warmth, but a practical fruit grower assured me last year that he had dressed all his cankered Apple trees with "soluble paradim," with the result that the malady entirely disappeared and a healthy and vigorous growth followed. If this be so, these high-flavoured, though capricious, Apples may yet be grown with more certainty than heretofore. Really good late dessert Apples are, perhaps, the scarcest of all, but Fearn's Pippin, a constant cropper, in the way of Blenheim, but smaller, and suited to all climates; Spice d'Arcy, sometimes called Baddow Pippin, an Essex Apple, small, but delicious, and a good bearer; Sturmer Pippin and Court Pendu Plat may be planted with confidence. The last-named is so late in blooming, that it seldom gets injured by frost. I have seen good showy and well-flavoured fruit from trees about Bury St. Edmunds. It keeps sound and plump till May. King of Tompkins County, an American Apple, large, showy, and of extra good quality, must be mentioned. Very few large Apples are so richly flavoured, but although my experience of it is limited to cordons, I learn from good authority that it is tender, and never likely to become a market Apple, at any rate so far as English grown fruit is concerned. Could we but impart to it the cropping powers of Lane's Prince Albert, it would indeed be an acquisition. Lastly, that good old-fashioned late Apple Scarlet Nonpareil should be grown in every orchard and garden. I saw a beautiful dish at Earl's Court exhibition in May, 1892, as plump and fresh as could be desired. Its rich scarlet colour and good flavour are further points in its favour.

J. CRAWFORD.

**Grape Muscat Hamburg.**—The interesting notes that have appeared in THE GARDEN recently should be helpful to growers, more so if the writer would in all instances give soil and under what conditions the Vines are growing. About fifteen years ago this kind used to be grown well at Farnboro' Hill, Hants. I well remember seeing bunches of it from 4 lbs. to 6 lbs. in weight, perfect in colour, and not in the least shanked. Mr. McLaurin, the gardener, considered it wanted a warm open border. No doubt the dry nature of the soil was favourable to it. The border, which was an outside one, was heavily mulched and kept well watered in dry weather.—J. CROOK.

**Apple Mannington's Pearmain.**—I have a pyramid tree of this, and for the last four years it has never failed to crop, although growing in an exposed condition. I am now—January 26—sending it to the table, and very good it is. The flesh is yellow, tender, rich and juicy, and highly flavoured. I find it desirable to allow it to hang on the tree as long as possible, as it is apt to shrivel if gathered too early.—J. CROOK.

—This is a valuable dessert fruit, as it remains good well into March, and now the fruits are delicious. It may not find favour with those who prefer a large Pear, but it is large enough for dessert and one of the best flavoured fruits in season at this date. Of varieties of Apples we have too many, but this is one of the kinds we want more of. It does well as a pyramid or bush. It is not a strong grower, being compact and well suited for a restricted area. The fruits are greenish-yellow, with a brighter colour on the sunny side and russet markings. To keep it well into the spring the fruit should be left on the trees as late as possible, as if gathered early or kept in a warm store, it shrivels badly and loses flavour. It thrives well in light soil and fruits freely in a

small state. I have cordon trees of this variety which fruited the second season after planting.—G. WYTHES.

## FLOWER GARDEN.

### 1894 IN SOUTH DEVON.

IX looking back over the last twelve months, and critically assessing the merits and demerits of 1894, it is impossible to arrive at a conclusion other than that its drawbacks in the way of weather considerably outweighed its advantages. The year commenced with bitter east wind and frost that sent the thermometer on the Grass down to 11°. Then came the snow—15 inches deep over everything. Then a rapid thaw and mild weather until almost the end of February. March was dry and cold without any great range of temperature. April was the only really satisfactory month of the twelve—absolutely frostless; a month in which the winds were quiet, a fair amount of rain fell, and everything promised well for a prosperous year. This hope was soon dispelled, for May was cold and windy, with a frost on the 21st, which, however, was too light to do any damage to speak of in this particular neighbourhood. June was more windy than May, and cold until the last week. July and August were likewise very windy and unsummer-like, and with the last day of August the last hope of summer vanished. September was fine and still, but colder than the average for the month, while October, November, and December were unseasonably warm, the first two being also extremely wet.

The season has been an extended one for flowers, Dog Roses having been picked on May 9, and perfect buds of Safrano from the open wall on December 30. Magnolia grandiflora was in bloom for nearly six months, the first blossom opening towards the end of June and the last being cut on December 2. Heliotropes that had been left out remained unhurt by the frost until the last day of the year, but in spite of its length the flower season was unsatisfactory, winds, rain, and the ungenial weather militating against an effective display. Subtropical flowering plants, such as Hedychiums and Cannas iridiflora Ehmanni, were far inferior both in leafage and bloom to what they were in 1893. Clumps of Agapanthus umbellatus planted out, which have flowered well in other years, showed no signs of beauty of Phacelia campanularia was cut short prematurely.

We are now experiencing the effect of the season on certain bulbs and tubers. Freesia refracta alba has, seemingly, refused to ripen at all, a large collection of this charming Cape bulb which year after year has given an abundant harvest of deliciously scented blooms soon after Christmas having thrown up but a solitary flower-scape here and there, and Arums which are grown in quantity and particularly well at an establishment in the vicinity have not flowered so unsatisfactorily for ten winters; while doubtless the damp was a predisposing cause in the case of the Liliun candidum disease, which was rampant during the past summer.

What legacy has been left us by 1894, as far as the present year's crop is concerned, will not be known yet awhile, but it is well not to be too sanguine as to the result. For plantations of young fruit trees made in the winter of 1893-94 there is no doubt that the past year has been favourable, as they have taken hold of the ground well and have made fine growth. In

the flower garden, too, there are bright spots to turn to, the Bamboos and shrubby Spiræas having grown remarkably, and many herbaceous plants have been benefited by rather than suffered from their late experiences.

Many vegetables, more especially Seakale, have not been equal to the samples of 1893. Outdoor Tomatoes were a complete failure. The Pear crop was a very heavy one, and Apples, from young trees on the Paradise, were plentiful, with the exception of Cox's Orange Pippin, of which, I understand, the crop was poor throughout the country. Strawberries, although untouched by the frost, were not so heavy a crop as in 1893, but bush fruit was an average yield.

It is not seemly to speak ill of the departed. We will, therefore, content ourselves with expressing a hope that 1895 may deal gently with us, for most of us feel the need of a little indulgence after the rigorous, but doubtless salutary lessons we have received from his blustering and gloomy predecessor. S. W. F.

A NEW LYCHNIS.

THE illustration represents a most beautiful flower, which, unfortunately, like many other good things, is the bearer of an absurdly long name. It is called *Lychnis Flœ-cuculi plenissima* Ad. Muss., and is very distinct from the ordinary and well-known form of the double Ragged Robin. The engraving was made from a photograph of a plant growing in a sloping rocky border in the nurseries of Messrs. R. Veitch and Son, Exeter, where it has flowered continuously from early summer till late in autumn. Of its hardiness there can be no doubt, as, in spite of its having been laden with an abundance of flowers during the whole of last summer, the plant has stood a severe winter without protection of any kind, and at the time

A new fringed variety of the double Ragged Robin. Engraved for THE GARDEN from a photograph sent by Mr. F. W. Meyer, Exeter.

sent no difficulties whatever, as I saw it flourishing in ordinary somewhat heavy loam mixed with a few stones. The plant is still scarce, but it is sure to become a general favourite. The only thing against it is its name, and it is to be hoped that this will be changed to *Lychnis fimbriata*, *L. laciniata*, or some other short appellation more suitable and expressive than the one given above. For a popular name perhaps Fringed *Lychnis* might do. M.

CHRISTMAS ROSES.

HELLEBORUS NIGER ANGUSTIFOLIUS, one would think, could not be much excelled when seen well grown and clean. There are good varieties I know, the flowers of good form, and if not quite pure, the tints can scarcely be considered faults, but in most kinds excepting this one there is to my mind a feature of coarseness in the dark coloured stems, bracts, and often the under parts of the sepals. It is because this kind has clear, pale, delicate, or apple-green stems, and flowers of the snowiest whiteness without tint and of good size and shape withal that I value it. Moreover, unlike most vars. of niger, it produces as a rule long scapes. In the Bath variety and several others you would scarcely get the convenient long stem without the aid of hand-glasses or the forcing pits. I do not know after all that the long stems when normally grown are of much moment, because if you want to keep your Christmas Roses clean and serviceable, the shelter needful for clean flowers helps to secure this feature by drawing out the scapes of all the varieties. Another good quality I like in this kind is its robustness, and the facility, owing to its free habit of growth, with which it can be propagated and transplanted. Perhaps the readiest and most profitable way of dealing with it is to arrange the plants so that they can be covered with ordinary garden frames or lights. In November or earlier all that would be necessary would be to give a dressing to the plants to clear them of slugs, afterwards washing them down and bringing over them the lights or cold frame. This method secures perfect flowers free from slug grazing and splashes, and otherwise facilitates the future health of the plant, for if the frame is left long enough there can be no doubt that the dryness and partial protection from frost will benefit the plants and keep their foliage in better condition.

The niger section of the genus *Helleborus* is unmanageable in some districts. I have heard from several correspondents in the western counties that they cannot keep a presentable plant of any of the Christmas Roses, and in each case I know my correspondents to be expert gardeners. At the same time it is known that in their gardens the other species of *Helleborus*, the so-called Lenten Roses, flourish. This is a fact that can hardly be said to help one in finding the cause for failure of the niger section, though I believe that the two sections are widely distinct botanically in many ways, and especially in the features of their roots. I believe the facts that are available on this subject are such, that were the causes of the failure of *Helleborus niger* in certain districts to be investigated, they would form data sufficient and reliable to go upon, and I for one should feel very grateful for the views of those who have studied the subject. Personally, I have no difficulty whatever with any of the *Hellebores*, but during twenty-five years of considerable correspondence, and no time more than the present season, I have heard laments that the Christmas Roses cannot be grown successfully. There is one simple mode of culture, which was taught me by Mr. Moore, of Glasnevin, which proves of great benefit to plants where they do

not otherwise refuse to grow in the above described manner. It is that of planting at a fairly good depth in land of deep tilth, and, when the plants had become fairly established, mulching annually with well-decayed manure or vegetable soil. I am not for a moment suggesting this as a mode of planting to meet the above-mentioned difficulties, because I believe this and even more have been done in trying to coax new plantings, but I am sure of this, that it may be made the means of invigorating old plants in a remarkable degree and in a comparatively short space of time. I do not care for manure being incorporated with the soil when plants are first set out, and I always give it on the surface. J. Wood.

THE SHOW AURICULA.

THE Auricula fancier divides his favourite flower into four sections, the green-edged, grey-edged,

Auricula Mrs. Moore.

white-edged and self-edged. None of the green-edged varieties have farina on the leaves, and a good green-edged variety should have none on the edge of the corolla. All of them have, or ought to have, a yellow or orange tube to the corolla, and the centre of the flower should be densely coated with farina; next, a blackish or deep purple irregular band, as seen in the woodcut, and the edge of green, grey, white or the dark band entirely covers the margin, forming a self edge. All the classes, except the green-edged, have mealed or green foliage, sometimes thinly laid on and in other instances the meal so thick as to entirely cover the green of the leaf underneath. No plant is so easily grown as the Auricula if it is not stifled under glass. If the Auricula is grown under glass the plants should be placed in ordinary garden frames. The glass lights should only be used to keep the plants from excessive wet. In dry weather, even if cold, the lights ought to be drawn off. Even when the plants are put into glass houses in the spring air should be given freely and the plants kept quite near the glass roof. This nearness to the roof promotes and

of writing (January) is already pushing forth its young growth for the coming season.

The plant when in bloom forms a handsome bush about 18 inches high and 2 feet in diameter. The foliage is like that of its relative, the Ragged Robin, but the flowers, which are borne in loose panicles, are very much larger, very double, and beautifully fringed. The colour is a bright pink, and its wealth of flowers is almost phenomenal. Its culture seems to pre-

maintains a healthy and compact growth. After the last days of January the flower-trusses appear. Most of the fanciers now-a-days have light, airy glasshouses, and they place the plants in these for the convenience of attending to them and watching with some degree of comfort the development of the trusses in inclement weather. Most of them have a heating apparatus to keep out frost merely. The potting soil ought to be good decayed fibrous loam. I find the best is that obtained from a common where Bracken grows. Add to it a fourth part of decayed manure, with as much leaf-mould and coarse sand if necessary.

J. DOUGLAS.

#### FLOWER GARDEN NOTES.

**TUFTED PANSIES.**—The note in a recent number as to the exceptional growth made by the majority of herbaceous plants right through the closing months of 1894 is especially true of tufted Pansies, an inspection of the beds showing that with one exception all varieties started away well from the planting, made capital growth, and are now nice, bushy little plants that, given favourable weather, will be very early in flower. The exception is *Duchess of Fife*, which, I regret to say, gets the disease badly, and of which, consequently, good cuttings are not easily obtainable. I notice with much surprise that the recommendation is still occasionally given to keep tufted Pansies in the cutting bed until the spring and then plant out. It would be interesting to know what are the exceptional conditions that necessitate such treatment. It cannot be that very severe weather is feared, for they have come safely through a winter when for several successive nights the glass has dropped to within a few degrees of zero, and even a combination of damp and severe cold would hardly affect such a moisture-loving plant. There are few places in which treated as if thoroughly hardy they will not do well, the exception being, perhaps, in those flower gardens where the soil is poor and dry and the subsoil very porous. Even here, however, they can be grown with a fair amount of success if a compost consisting of two parts heavy road sidings and one of cow manure is incorporated with the natural soil and the surface gets a good mulching as soon as possible after planting. If, on the other hand, the natural soil is so heavy that it works badly, it is a good plan to mix with it a liberal dose of spent Mushroom manure and leaf soil in equal proportions. To secure a long flowering season, cuttings should be inserted in July or very early in August, shaded a little, and kept thoroughly moist to secure a quick formation of roots, and planted out as early in October as the beds can be prepared. A mulching of Mushroom or peat moss manure will be found conducive to rapid growth and early development of flower, and, as above stated, is especially to be recommended for light soils. Where the plants are still in the cutting beds it is needless to say that they should be transferred to permanent quarters as soon as possible, lifting carefully to prevent mutilation of the root. It may be noted that it is the safer plan to make sure of cuttings rather than trust to later propagation by division when a considerable increase in the stock is contemplated. This latter is, of course, always practicable with the *Violetta* type and a few stronger varieties, but there are many now included among tufted Pansies that are hardly more amenable to propagation by division than the true Pansy.

**CARNATIONS.**—Nearly all remarks made on tufted Pansies are applicable to Carnations. The best display is always obtained from plants that are put out early in autumn, and if suitable soil is provided, early layering practised and due attention given, there is not much difficulty in securing good plants at that time, especially in a season like 1894, when an over-average rainfall was conducive to early root-formation. If planting was left over from the autumn, it should be put in hand as soon as the state of the weather and condition of the ground will permit. It is the knowledge

that in some seasons such conditions are not obtainable until February is well advanced that is one strong argument in favour of autumn planting. Only on one or two occasions, when the summer has been against the chance of securing good grass until late and the layers in October were but poorly rooted, have they remained with me on the old plants until the spring. If not already done, the Carnation beds may receive a mulching, and if allowed to remain on the beds throughout the summer it will be found capital stuff to incorporate with the layering soil. Such a compost is essentially moisture-holding.

**SPRING BULBS.**—Unless we get exceptionally mild weather, spring bulbs (I was thinking more especially of Daffodils) will be nothing like so early as in 1894, a result probably due to the difference in the immediately preceding summers, for, whereas in 1893 the great heat and prolonged drought were answerable for an early ripening of the foliage and an early starting of the bulbs, the conditions last summer were exactly reversed—the foliage remained green until very late in the season, the ripening of the bulbs was deferred and the starting into growth for the present season proportionately late. Where Daffodils are in great request as cut flowers it is well to note the date of flowering (in an average season) of the different varieties as they are obtained, so that one may increase or diminish their numbers as they are likely to be required. These remarks naturally apply to flowers for cutting, and not to their naturalisation for effect in the flower garden and pleasure grounds. Here they will be used as they may be best adapted to different soils and situations and in variety, that the flowering season may be prolonged as much as possible, only it must be remembered that each separate clump should be composed of one variety. Naturalisation becomes a farce when there is an indiscriminate mixture of trumpet and chalice-cup flowers, representing the months from February to May.

**FLOWERING SHRUBS.**—Beds of these may have their final tidy up for the season, any little pruning required finished, and when, as often happens, the beds are in the immediate neighbourhood of trees and are fairly covered with autumn leaves, the latter can have a thin coating of half-decomposed leaf soil shaken over them instead of raking over the beds. This treatment may be specially recommended for hardy Azaleas and all shallow-rooting American plants, and on poor, dry soils if cow manure can be substituted for the leaf soil so much the better. Whilst on this subject I should like to caution those who are answerable for the cutting in connection with the flower basket to be very careful in their treatment of hardy Azaleas. The careless flower gatherer is apt to nip here and there, spoiling the appearance of the plant and encouraging a lot of small growth that is of no earthly use, besides damaging the prospects of a good display of flower for the next season. The proper way is to take those flowers that are on straggling, awkwardly placed shoots, cutting to a back break that is likely to develop into a strong serviceable shoot. The ordinary *A. pontica*, about the sweetest member of the family, as it is when in mass one of the most showy, was planted here rather largely in the old days, but, unfortunately, in rather a strange manner, dotted here and there among common Rhododendrons instead of in bold masses. No notice was taken of them for many years, the consequence being that in the majority of cases the Rhododendrons had nearly smothered them, and the Azaleas grew tall, but very straggling. By dint, however, of heading them back and cutting the Rhododendrons well away from them we have converted them into very fair specimens, and very effective they are in the flowering season, dense masses of yellow set, as it were, in a framework of evergreens.

Clarmont.

E. BURRELL.

**Common garden Thyme.**—It is worthy of notice how well this thrives on old house walls. Our garden walls are of this material, and on one portion of them we have an abundance of Thyme. However

severe the winter, it does not get killed, while that growing on the level ground is often cut down. That on the wall grows hard and wiry compared to the other.—J. CROOK.

**The Gladwin** (*Iris foetidissima*).—When at Torquay in November I saw hundreds of clumps of this plant in the hedgerows by the roadside, and handsome they were, laden with a profusion of orange-red berries. In the neighbourhood of Chudleigh, a few miles out of Exeter, I saw much of this *Iris* growing on the dry woodland banks and hedgerows also. From what I saw of it there I resolved to grow it for its ornamental red berries during the winter.—E. M.

**Statice latifolia.**—This a good late summer flowering perennial either for the border or for the rockery in a good open spot where a deep root-run may be afforded it. It is the showiest and most vigorous perhaps of the hardy kinds, and seen in bold groups in full flower forms quite a distinct feature. The plant may be raised from seed, though this is not always to be depended upon, particularly after a somewhat sunless summer like that of 1894. A better way of raising stock, and certainly a safer and quicker method of obtaining good plants, is by cuttings of the root. Judging by appearances, there is no indication that the plant will increase in this way, as all the growth usually springs from a forked head at the crown. But if a plant is lifted and some of the roots detached and cut into lengths of a couple of inches or even less, a good stock may soon be obtained. The stronger roots will even bear being halved or quartered, though such extremes are rarely needful outside a nursery. Insert the pieces of roots in a pot in sandy soil with the apex just protruding, and where possible place them in warmth in the greenhouse, or, better still, in slight bottom-heat. In a few weeks small breaks will appear, and as these progress gradually harden off and treat subsequently in the usual way of cuttings. By the month of June with careful treatment the young plants will be ready for planting out in their permanent positions.—E. J.

#### HARDY HERBACEOUS PLANTS FROM SEED.

THE time is drawing near when the sowing of seeds of choice perennials should receive attention. Many amateurs probably working on the system of "sowing the seeds as soon as ripe" will have sown such as they were themselves able to secure in the past summer and autumn. I do not consider that anything is gained by sowing seed as soon as ripe, but rather the reverse. One very obvious disadvantage of the system is that some species and varieties of plants germinate so quickly, that they appear above ground at a season of the year by no means favourable to their well-being. And even supposing them to be sufficiently hardy to endure frost with impunity, there is the additional risk of the seedlings being devoured by slugs. For these reasons, therefore, it is always advisable to delay sowing the seeds for a month or two after being collected—sufficiently late, in fact, to ensure their remaining dormant through the winter months. It is a very common practice to sow the majority of seeds in pots, pans, or boxes of fine soil, though I am by no means convinced that this is the safest and best way. Of course there are risks and uncertainties whatever method is employed, though I incline to the belief that the greater risk is encountered when the seeds are sown in well-drained pots. These latter are too often an obvious evil, by reason of the frequent and repeated waterings which become necessary—an operation responsible for the loss of much good and valuable seed. A far simpler way, and I venture to think a much safer one at the same time, is that of sowing the seeds in the open ground, or in ground at least that can be

protected overhead by a spare light. For many things even this protection would be unnecessary, particularly for the stronger growing kinds, such as Lupines, Hollyhocks, Gaillardias, many Poppies, Everlasting Peas, and others which germinate quickly and soon make vigorous plants ready for transplanting. Such as these may be gathered together in one block for instance, while another may be set apart for such things as *Coreopsis*, *Campanulas* of the Peach-leaved section, also *C. latifolia*, which, though somewhat strong growing, has seeds of small size. This batch should also include such things as *Adonis*, *Geum*, *Lycnis chalcidonica* and *Haageana*, *Dracocephalum*, *Sweet William*, *Columbines*, *Agrostemma*, *Armeria*, and many others; while a third section could well be made up of many species of *Primula*, also *Polyanthus* and *Auricula*, herbaceous *Lobelias*, *Lycnis Lagasce*, *Campanulas* of the *turbinata* group, also *fragilis*, *isophylla*, and indeed any of the very minute-seeded kinds that require either sowing on the surface merely or with a very slight covering. All such as these repay for sowing in a frame which may be darkened at will, and thus save much labour and anxiety in watering. In this latter the soil should be prepared by digging and an inch of finely sifted soil added on the surface and made somewhat firm. Using very dry soil on the surface will dispense with adhesiveness in firming. When this is done a good watering may be given and the seeds sown thinly on the following day, marking out a small plot for each and labelling as the work proceeds. Provided a good watering be given at the start and the frame darkened, little else will be needed for some time.

All the larger seeded kinds in the open will be best sown in shallow drills a few inches apart, protecting them from birds and cats by sprays of Gorse, Holly, or similar things. For very rare and choice alpiners, or such as may take a long time to germinate, for example, some of the *Gentians*, *Hellebores*, *Hepaticas*, *Primulas*, &c., it is a good plan to sow the seeds in pots in the usual way, afterwards standing each pot in a saucer of water. By supplying the water in this manner the soil will be kept moist without fear of disturbing the seeds by repeated surface waterings. In adopting this method it will be necessary now and again to allow the saucer to become quite dry, otherwise the soil may become sour. If the pots are covered with darkened glass and occupy a shady place, they will only require occasional fresh supplies of water below to keep the soil sufficiently moist.

It is not safe to discard seed-pots for at least two years, as many things are slow to vegetate. This is particularly true of *Trollius*, *Anthericum*, *Hellebore*, and many other things even when freshly gathered seeds only are employed. Indeed I have more than once thought that the sowing of freshly gathered seeds is a mistake, and that some species at least produce equally good results and germinate more quickly when seemingly kept for a few months. For instance, I have experience of *Helleborus* taking three years to germinate, and *Trollius* and *Anthericum* nearly two and a half years when the seed has been sown as soon as ripe. These seeds were fully ripe when collected even to falling, while others of the same batch kept over have appeared above ground in a little more than half the time in the first named, and considerably earlier in the others. *Dictamnus* has some peculiarities also when raising it from seed, and much variation and uncertainty also exist among the *Columbines*. Is it likely that seeds are influenced in this respect by the presence or absence of sunlight and sun-heat at

their time of ripening, and their vitality lessened or increased in proportion? E. J.

#### BEGONIA SEMPERFLORENS VERNON IN THE FLOWER GARDEN.

OPINIONS will probably differ about the value of this *Begonia* as a summer bedding plant. I noticed in *THE GARDEN* towards the end of last summer that more than one writer spoke rather highly of it for that purpose. I do not know if my experience was in any way singular regarding it, but I cannot say that I was particularly struck with it, because when grown alone in a bed there was a good deal of sameness about it. There is not distinction enough between the leaves and the flowers to please me. Another lot of plants in a bed that had a wide band of white variegated *Pelargoniums* round it was more effective, and the white variegation against the bronze foliage of this *Begonia* was a good contrast. I do not think that it can be successfully used in the flower garden unless it is associated with a plant with a different coloured leaf. A moderately sized bed, pretty well filled with plants of this *Begonia*, and a good edging of *Dactylis glomerata* would be fairly satisfactory, as what is wanted is something to brighten up the dull tone of the bronzy leaves. One point in its favour is that a good stock of plants can be raised from seed the same season they are wanted for use. Plants raised at the same time and treated in the same way as the tuberous-rooted *Begonias* will be large enough for planting out early in June. Last year I pricked the seedlings out into boxes, from which they were transferred to the beds. If I grow it again I shall pinch out the centre growth when the third pair of leaves are formed, as I believe this will make the plants more bushy, and altogether of a better form than when they are allowed to grow their own way. If not pinched they do not branch out sufficiently to cover much space.

J. C. CLARKE.

#### KITCHEN GARDEN.

##### HEAVY CROPS OF ONIONS.

HEAVY crops of Onions are objects of pride, and sometimes a source of profit to the grower, private gardeners in particular attaching considerable importance to them. This may be partly due to the fact that a good supply for home use must be maintained, and partly because no other crop shows so plainly on the surface whether or not it is a failure or success. Some gardeners who may have experienced no great difficulty in growing heavy crops are apt to undervalue what is being done by their contemporaries, many of whom find it far from an easy matter to grow Onions successfully. The seed may germinate evenly and well, or it may fail badly in places; the young plants may grow freely and strongly, or they come to a standstill and never thoroughly recover from the check. If thinning is deferred a few days too long owing to a press of other work, much harm may result from that, while in not a few cases thinning out has to be very cautiously carried out owing to the likelihood of the Onion maggot destroying the plants wholesale. Nor is this all. In not a few cases just when the bulbing or thickening of the base is going on strongly, mildew overruns the bed, and the crop if not completely spoiled is yet greatly impaired in value both as regards the weight and keeping properties of the roots. Then there is the difficulty to be faced in many backward gardens of the roots failing to mature properly, and everybody knows they must be ripened thoroughly if they are to be kept for winter and spring use.

For several years past exhibitors of Onions have been in the habit of sowing a pinch or packets of Onion seed, as the case may be, in heat in order to have a batch of plants for transplanting to the open in April. These early-raised transplanted Onions are found to far out-distance those sown quite in the open in February or March. Not only do they attain a larger size, but they also mature earlier—they never fail in this respect—and as a consequence invariably take precedence at flower shows held in August and September. Whether or not Onions sown early in February under glass can honestly be termed “spring-sown” it is no part of my business to determine. No judge would venture to disqualify them, and the practice thus condoned will always be followed. In America they have adopted the plan of raising plants in heat on a very extensive scale; it is found to be much the most profitable method of culture to pursue. If it pays well to follow the prize-winner's method in a land of bright sunshine in abundance, several acres of ground being devoted to Onions thus raised by single growers, how much more so is the practice desirable in this comparatively sunless country. Sowing the seed where the plants are to grow may seem the least laborious plan, but is it? What about the extra time that has to be devoted to thinning out, filling up gaps, hoeing and hand-weeding in the case of crops sown in the open. Then, again, sowing in heat admits of more time or affords better opportunities for getting the ground into a thoroughly pulverised state—a very important matter. Lumpy ground is about the worst that could be selected as a seed-bed for Onions, but during March the clods usually get a thorough drying from winds and sunshine, April showers completing the work of breaking them down. There is yet another point in favour of sowing under glass, viz., the great saving of seed effected. Those packets of choice or new varieties are very small indeed, and the prices in the case of older varieties are by no means inconsiderable. Sown in the open, allowance has to be made for failure, but in a moderately brisk heat seed that would fail in cold ground germinates readily enough, so that one-half less seed may be sown under glass than is necessary in the open. It may be thought that, owing to the already crowded state of the houses in most gardens, little or no room could well be spared for raising Onion plants in quantity, but this is far from being a serious objection. For instance, how much room would be taken up by six boxes each 24 inches by 12 inches? Space for this number could easily be found in innumerable early vineries, Peach houses being forced, and such-like, and in these enough plants could be raised to form in the open twenty-seven rows 20 yards long, the plants being disposed 3 inches apart, while if a distance of 4 inches apart in the row is allowed there would be thirty-six rows grown. The latter is perhaps the distance that would be most often favoured, and this means an Onion bed 20 yards by 12 yards, or, roughly, 8 rods of ground. If the latter was well prepared for the plants and what few other necessary cultural details are attended to, there should be a crop not far short of 40 bushels of sound well-matured Onions for storing in the autumn. For ordinary purposes, medium-sized to small roots are most to be desired, and planting at a distance of 3 inches apart should be most often practised. Exhibitors require extra large roots, and in this case planting from 5 inches to 6 inches apart gives the best results.

It is worthy of note that transplanted Onions, or any raised in the open during the autumn for the purpose, and also those raised

early in the year under glass, are far less liable to be attacked by Onion maggot, though they are no more exempt from mildew than are those sown in the open in March, unless early maturation can be considered a preventive. If wanted extra fine, then more than ordinary pains must be taken with the preparation of the ground. A change of site is desirable in cases where the Onion maggot proves troublesome, but successful growers of Onions use soot and artificial manures so freely, that it is not often they are much troubled by the maggot. As a matter of fact, some of the finest Onions shown in various parts of the country are grown in large quantities on the same breadth of ground every season. This site has been trenched so often and has had so much added to it in the shape of solid manure, road grit and strong composts, that it is now raised fully 1 foot above the ordinary level of the ground, and, as a consequence of this extraordinary culture, the Onions have so great a depth of rich, firm, yet comparatively warm soil to root in, that this partially accounts for the extraordinary success attending the practice. Evidently Onions require warmth as well as rich food and moisture at the roots, and if proof of this were needed I have only to refer to what is done by Mr. Smith at Mentmore. Nowhere else have I seen Onions grown on the ridges between the Celery trenches, and nowhere else last season did I see a more serviceable lot of well-matured roots. The ridges between Celery trenches will hold two rows of Onions without greatly interfering with the free passage to the trenches, and these sites could not be more profitably utilised. The least that can be done towards giving a trial to the plan of raising under glass and transplanting is to raise enough for most of the ridges between the trenches intended for mid-season and late Celery. If the work is done properly, there will be a capital lot of Onions for storing next autumn, even if the plan is tried in districts proverbially unfavourable to Onion culture. Those raised in boxes and planted out on the level should have a well-prepared site, solid manure having been dug in early in the winter, it may be with a view to sowing where the plants are to mature, though even more importance should be attached to the state of the soil as regards fine tilth. A supplementary dressing of 1 peck of soot to the rod, and forked in prior to planting, or else 2 lbs. of superphosphate of lime to 1 square rod at planting time, followed by a dressing of 1½ lbs. of nitrate of soda sown during a showery time early in May, will usually prove fully equal to promoting the growth of a fairly heavy and decidedly serviceable crop of roots. If the young Onions are somewhat drawn when the planting time arrives, shorten the tops to the extent of one-third of their length, and they will become more quickly established accordingly. Plant with the aid of a small flat or hollowed-out dibber, taking good care to spread out the roots in a natural manner instead of turning them up. They may be buried to the depth of 1 inch or thereabouts, and should have the soil pressed against the roots, a watering also being given if the soil is at all dry, while if the soil is moist at the time of planting, it may yet need watering a day or two later on. All that will be further necessary is to keep the ground free of weeds, timely stirrings with a Dutch hoe accomplishing this and otherwise benefiting the plants.

W. IGULDEN.

**Celery Leicester Red.**—There are so many kinds of Celery now-a-days, that the inexperienced are often puzzled which to choose. Were I restricted to one sort only, I would certainly prefer

Leicester Red. It happened to be employed in the garden where seed of it was sent for trial when it was first raised and before it was sent out. It was grown by the side of several of the then most popular strains. The winter was an exceptionally wet one, so much so indeed, that rot destroyed nearly all the other varieties; whereas not a single stick of Leicester Red was affected. Since then I have watched it in various gardens and in a variety of soils and found it to retain its rot-proof character. No better Celery could be grown for weight, crispness and quality, so that growers living in low-lying, wet districts would do well to give Leicester Red a trial.—J. C.

**Protecting Broccoli in frames.**—Recently some notes appeared on this, a writer remarking the best method was to take the plants up and place them under glass. For several years I have done this. The last two years I have laid them in in the old hot-bed where Cucumbers have been grown in summer. This was done about the last week in November, and now at the end of January I have some splendid heads of Veitch's Autumn Self-Protecting, enough to keep up the supply till the middle of February, when I hope to cut Early Penzance.—J. CROOK.

#### NOTES ON LETTUCE.

At this time many will be making up their seed orders, and a few remarks on the different varieties of this indispensable salad may, perhaps, be serviceable. For sowing in gentle heat now I have none to equal Early Paris Market; it has a nice sturdy habit, forces well, and forms small, solid, tender hearts of excellent flavour. Another advantage is that it may always be relied upon to come into use before those that have stood the winter are over. For succession, Veitch's Perfect Gem is really what its name implies, and stands hot or dry weather splendidly without bolting to seed. These are the only two Cabbage varieties that I grow in quantity for summer use, with Hammersmith Hardy Green for winter and spring use. Amongst Cos varieties, Paris White is a great favourite here, and preferred to all others during the past two dry summers, the hearts being large, white, very crisp, and of agreeable flavour. Paris Green is also liked, being only a little inferior to the White, but I found it run to seed sooner, and the leaves have a rather coarser mid-rib. Little Queen is a fine sort to turn in quickly and is of good quality, but here it bolts soon, and it would not do to have large quantities planted out, as many would spoil before they could be used. For winter and spring use Hick's Hardy White is a fine variety, doing particularly well on our warm soil, and is seldom injured by sharp weather. It is always ready for use before Bath Cos, a well-known and esteemed variety. I think it much better to grow only a few well-tried sorts rather than a number of untried ones that may disappoint the grower at a season when he most requires them. While growing, nothing in the garden seems to derive so much benefit from liquid manure as Lettuce: if given once a week no anxiety need be felt as to the size or tenderness of the hearts. W. G. C.

#### MARKET GARDEN NOTES.

IN walking through a West Middlesex market garden a few days since I noticed the adoption of a simple contrivance for getting some Rhubarb forward. A bed about 4 feet in width was dug out to the depth of a foot or so. The soil dug out was used to make a bank along the sides and ends, and some young Ash stakes were employed by being bent over the bed at certain distances to form an archway about 4 feet in height. Some strong roots of the Early Albert Rhubarb growing in a plantation hard by were dug up and placed thickly in the bed with soil between them, and over the roots a good covering of fresh stable manure, thick mats being employed to form a covering. With the wall of soil protect-

ing the roots at the sides and the covering of manure on the surface an early crop is certain, preceding by some days that taken from the roots in the open. In the case of the latter plantations advantage is being taken of the wintry weather to draw in the long stable manure brought from London, with which is mingled spent hops. The ground having been well cleaned over before the frost set in is now being covered with a good layer of this manure, which will not only keep the roots snug and protected during the winter, but also encourage an early growth. As the leaves ascend they carry up with them the long manure, which serves the purpose of a screen, protecting the young stalks from the cold easterly winds which prevail in March.

Green stuff of all kinds has been very plentiful during the autumn. Up to the time that the frost set in winter Spinach had been abundant, and frequent pickings were made. The effect of severe frost is to sear the leaves, but when a thaw comes with milder weather, the hearts of the plants soon become active and put forth leaves. Probably a good covering of snow would be as acceptable to the market gardener at the present time. Brussels Sprouts and Savoy Cabbages have furnished abundant supplies, and the stalks of the former are yet well finished. Savoy Cabbages have been remarkably good, but they are nearly cleared, perhaps because rain and hard frost after Christmas always prove so injurious to the crop. The earliest Coleworts came on rapidly towards maturity, though they are now receiving a check. Spring Onions promise well, though owing to the mild weather and the wet summer they have gone a good deal to neck. But the plant is a good one, and there is the promise of a glut in spring, as there was two years ago. R. D.

## GARDEN FLORA.

### PLATE 999.

#### CALOCHORTUS PLUMMERÆ.

(WITH A COLOURED PLATE.\*)

THIS fine species was given the above name by Professor E. L. Greene, of the University of California. It is, however, I think, identical with *C. Weedi purpurascens*, described in Professor Sereno Watson's monograph of the genus, but was not introduced into cultivation till two or three years back, when re-discovered and named by Professor Greene. This species and *C. Weedi* are closely allied, both, like the Mexican species, having fibrously coated bulbs, which are not common to any other Californian variety. The bulbs of *C. Plummeræ* are the largest known, being upwards of 1 inch in diameter, with a very thick coat. The plant is very noticeable on account of its strong and vigorous habit. The one solitary leaf grows to a length of 2 feet by 1 inch in width, and the stout flower-stem rises to a height of 2 feet or more, carrying numerous branches bearing from ten to fifteen flowers. The flowers are larger than those of any other variety, some of those exhibited at the Drill Hall on July 24 last being 4 inches across; the base of each petal is covered with long golden hairs. The plant was awarded a first-class certificate on the above date, and though not the most beautiful of the genus, it is a fine acquisition and well worth growing on account of its large showy flowers and vigorous habit.

As previously stated in the issue of November 3, 1894, with a little care and trouble *Calochorti* may be grown in the open border as easily as the majority of hardy bulbs, and when once

\* Drawn for THE GARDEN by H. G. Moon, July 20, 1894, in Dr. Wallace's garden at Colchester. Lithographed and printed by Guillaume Severeys.

this has been proved there will be, I feel sure, few gardens where flowers are cultivated for the sake of their beauty that will not contain them.

Colchester.

ROBT. W. WALLACE.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**CUCUMBERS.**—The weather of late has not been favourable to the well-being of the winter-fruited plants, not through lack of sunshine, but owing to the harsh cutting winds. Where blinds are used for night shelter, lowering them by day as previously advised during storms of wind will have proved a boon to the plants. Avoid too hard firing, rather allowing the mercury to descend a few degrees below the regular figure, especially in houses deficient of piping. In such cases a reduction in the damping down at nightfall is advisable. If red-spider has gained a footing, the foliage should be syringed with a weak solution of Fir tree oil mixed in warm soft water over night and the scum removed in the morning. A sunny day should be chosen, that dry foliage before darkness may be guaranteed. Both bearing plants and young seedlings will soon be helped on by lengthening days and increased sun-heat, so that feeding may be practised a little oftener. Young surface roots also being more numerous, top dressings, always shallow and consisting of open loamy material with the addition of one-fourth fresh horse droppings, may be given as often as they appear. Evaporating pans charged with liquid manure, always diluted to one-fourth its strength, will further aid in warding off insect pests. Where two or more fruits cluster together, remove all but one, and fertilising at this early date will be necessary in order to avoid yellow and useless fruit. Train as much as possible on the extension system, removing only the weaker shoots that stop the ingress of sun and light, and cover the pipes where in close proximity to the foliage with coarse porous material. During absence of frost a night heat of 70° will suit fruiters, 65° being better for plants which are growing freely. In watering, let the water be soft, if possible, and apply it at a temperature of 90°. December-sown plants with the first pair of rough leaves well developed may be planted out on small hillocks of open soil provided there is abundance of bottom-heat, but where this is deficient the plants had better remain in the pots for another fortnight.

**PEAS.**—In open, light soils and in favourable districts, sowings of first early Peas may now be made. These will succeed those now coming on in pots in frames, and which will be transplanted next month. I cannot name a better selection for this date than Chelsea Gem, Exonian, and William the First, these forming a slight succession to one another. In sowing let the drills be shallow, as drought is never likely to affect these early crops, and deep sowing often ends in wholesale rotting. The distance between the rows may be about the same as the height of the variety when fully grown, but if a little more space can be given, a few rows of early Spinach may be sown between. If practicable, it is well to cover the Peas before filling in the drills with a good coating of leaf-mould and burnt garden refuse, this preserving the seed until it germinates.

**BROAD BEANS.**—The present is a good time to make a sowing in pots or boxes of some good early sort, such as Mazagan or Green Windsor. These, if brought on in a little warmth and finally hardened off in frames, will transplant well about the second week in March, and will, if then protected by Spruce boughs, come in in good time. A sowing, according to space at command, may likewise be made of Seville Long-pod, a capital Bean for following Mazagan and very hardy.

**FORCING CAULIFLOWERS.**—Where Cauliflowers are wanted in quantity in June, or where the wintered stock of Early London or Walcheren has already bolted, a sowing in heat may be made of any of the small early-maturing section, such as Snowball. If the box or pan containing the seed is stood in an intermediate house, the young seedlings will quickly appear, when they must be freely thinned and kept close to the glass for a fortnight, after which a cooler house will suit them better until large enough to prick off into larger pans or boxes. Early Cabbage, such, for instance, as Ellam's or Cocoa-nut, may be reared in the same way, as may also Lettuce if a scarcity in the autumn-planted Brown Cos batches is anticipated.

**POTATOES IN POTS.**—Where Sharpe's Victor, Ringleader, or any of the short-topped early varieties were planted in pots early in December, growth will now be well advanced. Earthing up, if not already completed, should now be done and the haulm supported by neat, stout sprigs of Hazel. A little artificial manure may well be added to the compost. Avoid shading the pots by plants or fruit trees, or growth and tubers will both alike be unsatisfactory. Beware of too much water at the roots, rather erring on the dry side than otherwise.

**PEAS IN POTS.**—The same remarks respecting earthing up and supporting growth apply to batches of dwarf early Peas sown in November and now being forwarded in Peach houses at work or similar places, elevated, of course, upon light airy shelves near the roof glass. Feeding may also be practised on a liberal scale, and where too many have been left in the pots, thinning may still be practised. Although the gatherings from these are never large, they are very useful, immediately preceding those produced in frames. On fine days Peas under glass enjoy occasionally a good syringing overhead.

**PARSNIPS AND LEEKS.**—Where these are still in their growing quarters and the ground is wanted, they had better be lifted, removed to some convenient spot and laid in to their full depth, afterwards being covered with litter. Where roots of any favourite Beet are being saved for seed, they should be clamped if this was omitted in autumn, and a good thickness of dry Bracken laid over them. A Seakale pot should be fixed at the top of the clamp, being filled with Bracken during sharp weather and kept quite clear when mild, so as to admit air and prevent the tops from growing too much.

**GLOBE ARTICHOKE.**—After the snow and thaw, stools of Artichokes must be examined, as the protecting litter is apt to become too wet and rot the crowns. Remove it and replace with fresh, using it in a rather long state. Where offsets were taken off in the autumn, potted up and stood in frames or pits, they must now be looked over, and any decayed portions removed from the base of the stem. Good coverings of litter are requisite in very sharp weather, as the tissues being very tender are easily frozen through, rot following.

**CLEANING CROPS.**—The beginning of February is a good time to go through beds of winter Spinach, picking off all dead and yellow leaves, removing any large weeds with the hand from amongst the rows, and finally putting the Dutch hoe through the bed. This will admit air and warmth and encourage fresh spring growth. Quarters of Brussels Sprouts, Kale, and Broccoli should also be gone through and all dead leaves removed from the stems. Before digging or trenching any ground it will be better to clear off any stumps of Coleworts or other greens rather than dig them in, as they often produce a colony of grubs and injurious ground insects. All Broccoli beds should be examined weekly, and leaves bent down over all forward heads to protect them from frost. Fully developed heads may be removed with the stems entire and laid in in shelter. All clamps containing eating Potatoes should now be examined in open weather, especially where frost injured any of the tubers before they were lifted from the field in autumn, or rot may play

sad havoc. Sprouts also need removing, these drawing much of the goodness from the Potatoes. Advantage of frost must be taken to wheel manure on to all vacant plots, and even on those where cutting has not yet ceased, the material being tipped in large heaps and covered with a little soil to prevent the strength escaping and also for appearance sake where in sight of the mansion. While the roads are hard, gravel should be carted home for mending kitchen garden walks, this work being pushed forward with all speed, as also the renewal and planting of Box edgings. All faulty drains in this department should also be seen to. Labels for vegetable crops must also be made, Pea sticks cut in readiness for early rows, the spray or trimmings being saved for use amongst Beans and dwarf subjects generally. Stakes for seed crops in summer should also be prepared. Home-made frames may be provided for the accommodation of successive crops of Potatoes, French Beans, and Carrots, these not necessarily having glass lights, but straw covers, to be placed over the frames at night.

**SEED ONIONS.**—These should now be closely examined, any that are likely to be too far grown by planting-out time being used in the kitchen, and the rest spread out thinly in a dry, cool, airy place.

J. CRAWFORD.

### FRUIT HOUSES.

**EARLY PEACH HOUSE.** The early trees started in November or the first week in December will now be in bloom or on the point of opening their flower buds, and if the latter, no time should be lost in fumigating. It is best to fumigate lightly two or three times in succession. The borders must likewise receive attention in the way of moisture, giving water at a temperature of 80°. Should there be any premature bud-dropping, it is wise to err on the right side and apply water freely, as doubtless dryness at the roots tends to that end. When the flowers commence opening the temperature should be raised to from 60° to 65° by day and 10 lower at night. I do not advise a high night temperature, as better results are obtained by less heat after daylight ceases. With cold winds, hail, and snow, and only fitful gleams of sunshine, airing is a difficult matter, and in large roomy houses or those constructed of iron it is wise to keep the top ventilators closed, as should the thermometer run up freely, it will do much good. Sun heat at this time of year is invaluable, and should be retained as much as possible. Syringing overhead must cease whilst the trees are in bloom, but it is well to keep the walls, surface soil and boles of trees moist by damping down twice a day in fine weather, taking care not to wet the hot water pipes in cold weather, as dense volumes of steam are harmful. I am aware some growers do not advise moisture when the trees are in bloom, but I am of the opinion that, given as advised, it strengthens the flowers and creates a sweet atmosphere. At this dull period of the year fertilisation of the blooms will be necessary. The pollen is readily transferred with a rabbit's tail. I prefer this to a brush, as it is light, and the least touch suffices to set the flowers. Many of the old varieties bloom so profusely, that it is a good plan to let the smaller blooms take their chance, as the trees always set a great number of fruits.

**SUCCESSION PEACH HOUSES.**—Where there are several Peach houses the second one is generally started at the new year, and the buds will now be swelling freely. Such trees will require ample supplies of water in the way of damping all parts of the house and the trees, using tepid water. Should the hot-water pipes be close to the trees, I have found it advantageous to cover them for a time. This covering will cause a moist atmosphere, as the heat may be slightly raised during the day, giving 5° to 10° higher than when the house was started. I do not advise raising the night temperature till the bloom begins to expand. In mild weather 45° to 50° is safe, as if at all high there will be trouble with bud-dropping.

This does not apply to sun heat. On dull cold days it is not well to exceed 50° to 55°, doing what forcing is required during daylight, maintaining as regular a night temperature as possible, as a fluctuating temperature is the beginning of the grower's troubles. Some varieties—especially the American Peaches of later introduction—drop their buds badly, and I have found a temperature a few degrees higher than advised beneficial. Now is a good time to water to assist in swelling the flower-buds. Owing to these trees blooming later there will be more sun-heat, and it is a safe plan to reduce the buds if there is a superabundance, as there will be no fear of a bad set with well-managed trees. It will also be found that the wood buds now will move very quickly, and it is a good plan to begin disbudding at the earliest moment possible.

**LATE PEACH HOUSES AND CASES.**—The work of cleansing should now be finished, even in cases, as the buds soon get injured. Should there have been any trees lifted or new trees introduced, it is well to get them pruned and the soil well firmed at the base, and as the trees rarely get too much moisture in such structures, any overflowing tanks of rain water may be made good use of by giving old or large trees a thorough soaking. The walls should be washed over with fresh lime after the pruning is completed. Should brown scale be troublesome it is well to paint the older wood or main branches before placing in position, using a thick solution of Gishurst, clay and sulphur. Many cultivators leave their trees from the wall or trellis till the last moment, but as there is so much work later on, time is saved by doing the work now, giving all the air possible to keep the trees back. Large trees which bear freely will repay rich surface-dressings at this season, using such materials as turf loam, bone-meal, wood ashes, old mortar rubble and some good fertiliser.

**HARDY FRUITS.**—Though the weather may not be all one could wish, it is necessary to push on with the work of pruning, nailing and training. In frosty weather manures can with advantage be placed in position for covering when the weather is open. It is well to remove the top surface, which is often weedy, before placing the new materials, as the borders then do not get raised too high. I have noticed this winter the borders of wall trees are anything but moist in light soils, and as there is often liquid manure running to waste at this season, this may be given to such as Apples, Pears, Cherries and Apricots. To prevent the manure, which may be thick, leaving a deposit on the surface, I have found it a good plan to remove the surface soil before applying the same, this assisting the liquid to reach the roots more readily, the soil being replaced when the watering is finished. Doubtless the summer of 1893 dried the soil so much that the moisture has never got under large trees with fibrous roots, so that the food given now will be beneficial. Apricots with their roots near the surface, also Cherries, are gross feeders. I do not advise giving liquid manure to trees in bloom; it should be done after the fruits are set. The covering of whatever kind should be got ready for Apricot trees, which will soon be showing their flowers. I prefer such a covering as will admit light and not weaken the blooms. A temporary coping is of great benefit; indeed, I have more faith in an efficient coping than any other protection. The next trees needing attention are Peaches and Nectarines. These should be pruned at the earliest date possible, and the walls cleansed previous to nailing. For this purpose I use soluble paraffin and warm water. Ordinary paraffin is soon prepared by thoroughly mixing with soft soap, and when mixed adding warm water. Should the trees be dirty, now is a good time to cleanse them, washing first with strong soapy water, and painting as advised for indoor trees. I do not advise re-nailing Peach trees till the last moment, as if kept from the wall the buds are later. It is well to fasten the leading branches securely to prevent damage by winds. When the pruning and nailing of wall trees are finished the borders should receive attention.

These are often neglected if left till the busy season. Before giving these aids it is well to examine the soil and see what condition the roots are in, as if far down they do not reap so much benefit from surface-dressings. In such a case I would advise removal of a few inches of top soil or going down to the roots and placing the manure over them, giving a covering of soil over the manure. Fruit trees in the open may be top-dressed, and Pears if strong well repay for liquid manure should there be any to spare. To get the most value out of the liquid give a dressing of short manure on the surface previous to applying the food. Any old beds, such as Cucumber or Melon beds, are useful for this purpose if better manures are not available.

G. WYTHES.

## GARDEN SKETCHES.

### CHAPTER VIII.

"The coming Musk Rose full of dewy wine,  
The murmurous haunt of flies on summer eves."  
MILTON.

**JULY 1.**—At last delightful showers have fallen by day and night. The hot and dusty air has become fresh once more. Raindrops lie hidden in the Rose petals and tremble on the Lilies' verge, and are folded in the shining leafage; the pent-up fragrance is set free again, and the incense of the flowers ascends with the breath of morn and floats in the evening air. Nature is indeed rejoicing, and so are they who feel her every mood.

It is the time of Roses and Lilies. The pure Madonna Lily (*Lilium candidum*) is not happy with me, planted no doubt in a too-shaded spot. I have noticed it lately full in the mid-day glare, in cottage gardens alongside the hot and dusty roadway, blossoming in splendour. *Lilium testaceum* seems easier to satisfy, and is a most stately flower when grown in large clumps. Just at present it has a charming setting, as one passes along the herbaceous border, for the fairest of blue Delphiniums is towering by its side. Elsewhere a tangle of faint blue Cornflowers is caught among its stems. I find this Lily equally content in sunshine as in shade. The white Rose of Provence is not a robust grower, but its blossoms have a fragrant delicacy of texture and a milky whiteness that are quite unique, and are well worth any extra care bestowed. The China Roses are now flinging wide their floweringsprays. Fellenberg is a particularly vigorous variety. Cramoisi Supérieur is more single, but its crimson is so intense as to make it a most striking Rose. The white China Rose, Rival de Pastum, is alike exquisite in blossom and foliage, and we may well believe that this was the Rose mentioned in Virgil's writings. Cuttings of these old-fashioned Roses when taken now strike freely under a bell-glass in some half-shady spot. Many such that were made just a year ago are showing blossoms now, but I have had them nipped off so as to throw the strength of the plant into the formation of fresh shoots that later on in autumn may be allowed to flower, the great charm of these China Roses being their fearless blossoming until cut off by the frosts of winter. The success of Rose cuttings seems chiefly to depend on their being planted in the ground two-thirds of their length, and then pressed in as firmly as possible, a portion of ripened wood at the base being, of course, necessary in the first instance.

**JULY 17.**—St. Swithin's Day came with clouds and showers, and now we have rain with thunder and sweeping winds. This morning there was a Rose-leaf storm in the garden, when the crimson petals were torn from their stems and whirled high against the inky rain clouds

beyond. The Iceland Poppies are very gay at present in all their shades of orange-red, bright yellow, apricot, and pure white. An entire bed of them open in the sunshine and nodding together in the light summer wind will give brilliance to whatever spot they may be in. They are excellent for indoor cutting arranged with their graceful buds in amber glasses and the light *Gypsophila paniculata* (which I call Sea Spray) used to support them, their blossoms gleaming brightly through the delicate flower mist that surrounds them. The old plants are of little use, so they are grown as annuals each year. The flowering sprays of another plant—*Heuchera micrantha*—hold blossoms together very lightly. Seen in the distance when growing the tall stems are beautiful caught together in a red misty tangle of some hundred sprays, that when gathered form a delicate support for bright blossoms such as the summer Gladioli, that always tumble aside in a vase of any width, or the yellow *Oenothera Fraseri*, with its slender crimson stems and buds. *Stenactis speciosus* has great staying power, and so is a valuable border plant, its oval green eye set in the fringe of amethyst petals making it distinct from the Michaelmas Daisies. Storm and rain do not injure it. Let but the sun shine out, and it is quickly dry and bright again after its rain bath. Frequent root division makes it more vigorous.

Among shrubs in blossom, *Escallonia Phillipiana* is one of the most charming. The slender arching branches are clothed with small white blossoms, so that they look as if set with pearls and render it quite distinct from the other varieties. It has not the rapid and somewhat coarse growth of *Escallonias* in general, and so is fitted for choice positions. The large trees of *Berberis Darwini* that were golden bushes in spring-time are now nearly as beautiful in their summer apparel of deep blue, every branch being completely draped with fruit like fairy Plums, with the delightful bloom veiling the rich hue beneath. The starlings sometimes light on them for a morning feast, but as yet they are untouched by the blackbirds and thrushes, which are still occupied with the yet lingering Currants within the garden walls. Long branches of these blue berries, set in brown jars with stems of *Moutbretias*, are our prettiest indoor flower group. Since the drought ended, *Zenobia pulverulenta* has made rapid growth and is sending up fresh tinted shoots from the base. The leaves are of a lovely pale blue-greyish hue, shadowed as if with crimson, and the pure white flowers, set in loose clusters, are like Lily of the Valley and droop in little waxen bells from beneath the leaves. A peaty soil and half-shaded position suit this American plant. It is not of the hardiest of shrubs, but it is one of our most precious. *Cassinia fulvida* is overpowering in its smell of honey, but is very pretty in its early flowering stage; and later on, if the flower-heads are clipped off when they turn brown and musty, the shrub will be restored to its golden hue. This season I notice round the base seedlings springing up, having lain dormant since last year. During the last few weeks the white pendent plumes of *Spiraea arifolia* from a few stems some 8 feet high have been lovely seen against the blue hills beyond. Even in winter, after the leaves have fallen, this *Spiraea* is of value, for the flowers, though brown, yet linger on the stems, and the whole plant makes a light and graceful tracery cast up against the distant landscape. *Spiraea palmata* and its white variety make a fine group side by side in the rock garden. The blossoms of the latter in its delicate sprays when just opening are like seed pearls. The crimson stems and

rose-pink flowers of the former make it very attractive, and even when the flowering is past the light network of seed vessels makes it still pretty. As the Spiræas are plants of damp meadows, they enjoy moisture, and Spiræa palmata is always seen at its best by a stream-side or bank of a pond. S. Bumalda is a slender rosy shrub of rapid growth. S. crispifolia, with its deep pink blossoms, has been a bright bit of colour for some time beside a grey rock. It is a compact bush, increasing very slowly in size.

The blossoms that come and go day by day have generally beautiful seed vessels, so that the plant when it has shed its petals of the hour seems none the worse, but, with fresh swelling buds, awaits the dawn to be reclothed. This is especially noticeable in the Cistus family. Robed in the morning with fluttering blossoms not yet free of their crimping bud folds, at evening's close they lie scattered on the ground beneath, while the tree, free of any withered bloom, stands erect with shining leaves and red-brown buds, that hold the satin petals and the capsules from which they have just fallen, clustered together to await the coming day. Cistus florentinus, amid a tangle of Rock Roses of varied tints, has been beautiful, they, too, letting drop their coloured banners at close of day.

JULY 25.—Is there anything more powerful to recall the days gone by than the scent of flowers? The garden is spicy now with the perfume of Carnations, Mignonette, and Sweet Lavender. The last brings back to memory an attic under the eaves of an old dwelling, where the blossoms were spread out to dry in the long summer days, afterwards to be enclosed in muslin bags and laid among the folds of snowy linen, and many a day have I climbed to that sunny chamber to strip the blossoms from their stalks, and listen to the swallows twittering on the house-top, and the cooing of the wood-queens in the tall trees close by, and to watch the peacocks from the little window strutting up and down in front of the long turf shed.

With the perfume of Carnations return to memory the Peaches gathered from the southern wall of my old home, where they ripened when the Carnations were in bloom, and many a one was eaten in the warm scented air of a summer evening, while the Carnation blossoms lay in masses, touched to richer glory by the sunset hour. Carnations are so much better from young plants that the layering of them should never be omitted during this month, for the young plants are then ready to be moved in September, and thus have time to become established before frosts begin. Slips and pipings can also be made in any shady spot. These latter are not generally sufficiently rooted to move before the following April. This season the Carnations were so much affected by the purple fungus that appeared in blotches over the leaves, that I threw out all those in the fountain garden, removed the soil from the beds, replaced it with some fresh loam from pasture land, added some leaf-mould and replanted with cuttings of last year, which have grown apace. This purple stain on the grass is the Carnation's cholera, and so infectious, that it is death to the plant unless each leaf is removed as soon as the disease is apparent on it. The old Clove Pinks—the sweetest of all—are especially liable to this complaint. Since moisture has returned the Montbretias have made rapid growth and give a delightful glow of orange-red in the rock garden. M. crocosmiellora is not so tall or leafy as M. Pottsii and flowers more freely, the blossoms

outstripping the foliage and being larger and more brilliant. The beautiful arched purple stems are many-branched, and beaded their entire length with flower-buds opening gradually from the base upward. No withered bloom is ever visible, as, perfection past, they drop one by one to mother earth, leaving the crimson-sheathed seed-pod. The Montbretias delight in a moist atmosphere and soil, and where these can be found they are among our most valuable autumn plants. When the clumps become too large they can be dug up in spring and torn to pieces, the larger bulbs being replanted and the remainder thrown away if not required. The spiny-leaved Eryngiums have been beautiful all this month, especially E. amethystinum, with its crown of red-admiral butterflies. Each sunny morning brought the fluttering, dazzling wings to lie expanded on the blossoms, the insect intoxicated either by its scent or its nectar into stillness. I have counted as many as nine of these butterflies on the plant at the one moment. E. alpinum in like manner attracted the wild bees, and so overcame them with its essence that they could be calmly lifted off the flower-heads and laid in one's hand, there to reel and stagger in the most drunken manner for about one minute, after which they would fly away, mounting high into the air. L. A. L.

(To be continued.)

## ROSE GARDEN.

### WINTER ROSES.

LECTURING to the Horticultural Club on the odour of Roses at the Hotel Windsor on December 11, I embraced the opportunity of noting the winter Roses in the markets, shops, and streets. The facts gleaned in such quarters could hardly be said to be encouraging to British trade. The bulk of the December Roses in London were of French or foreign growth, and they consisted chiefly of Mme. Falcot and Isabella Sprunt, with a few Safrano and l'Idéal. There were also a few English grown Roses, but while these were comparatively few and far between, French Roses, consigned in boxes of 100 each, may be said to have furnished the markets and overflowed into the streets. In front of the Royal Exchange and Liverpool Street Station these French Roses had also more colour than English ones of the same sort, and, being massed in hundreds, added to the colour which the Roses presented in single file hardly possessed.

The flower girls in the street were not slow to add to the colour of their Rose-buds. The purple glow of the foliage of some of our Teas adds greatly to the effect of the half-opened buds, hence to increase the body of purple foliage in contrast with the Rose-buds of cream or gold, not a few of these clever mounters had worked in one or more glowing crimson leaves of Berberis Aquifolium with the all too scant leaves of Mme. Falcot. There was, however, a striking lack of white Roses in the metropolitan streets and markets a fortnight before Christmas-tide, and surely it is not beyond the ability of our English growers to flood the markets with home-grown Niphotos Roses for Christmas as liberally as they are supplied with foreign Roses, Camellias, Azaleas, Lily of the Valley, Arums, Roman Hyacinths, and Tulips. I am glad to note that "U. S." has faith in Niphotos for winter work. I go further, and would challenge any Rose grower to name a white Rose that can equal Niphotos for quantity and quality at any season under glass. D. T. F.

**Imperatrice Eugénie** is the name given to three perfectly distinct Roses. M. Guillot sent out a Perpetual Moss under this name in 1856;

one year after M. Beluze introduced a Bengal variety, and three years before M. Oger sent out a Hybrid Perpetual. Such confusion is caused by this multiplicity of names that a trade grower is often accused of substituting a variety when in reality the only error was in not knowing for certain which class or section of Rose was alluded to. There are many similar instances to the above, and much unnecessary annoyance is caused by this careless naming.—R.

**Mme. Georges Bruant**, one of the hybrid Japanese Briers, resulted from crossing Rosa rugosa with Sombreuil, and partakes of the characteristics of both—almost pure white and semi-double. R. rugosa alba is a perfect single white; Sombreuil is very thin and of lemon-white shades. The result is a vigorous grower with a long bud and of truly perpetual-blooming nature, with much sweeter perfume than in the ordinary Rosa rugosa.—R.

**Moss Rose Cristata**, sometimes called Chapeau de Napoléon, and at others Crispée, was sent out almost seventy years ago, and if one gets hold of the true variety it is still the best crested pink of this class. It should not be confounded with the common Moss Rose, although both are very fragrant and somewhat similar, but Cristata is a much newer production and more mossy. Both are only moderate growers, best on their own roots, and need rather hard pruning.—R.

**The old Cabbage or common Provence Rose**, known in this country for almost three centuries, is still grown around London beneath fruit trees. It supplies a large number of partially crested buds, which when cut young are almost like the Mosses and very sweet-scented. Not a vigorous grower, but when on its own roots and allowed to sucker at will, it is long-lived and hardy. There are several home and Continental names for this old favourite in addition to the above—R. d'Hollande, R. hortensis, R. de Chou, R. centifolia communis and others.—R.

**Rose W. A. Richardson for exposed places**.—This Rose has a grand constitution. It grows and blooms most freely here on its own roots in bush form fully exposed to the eastern gales, continuing to flower late into the autumn. Whether grown on a wall or in the open it must not be cramped for room, neither must it be over-pruned. The weaker growths, especially those from the centre of the tree, should be duly thinned and the head generally balanced, but nothing further. It succeeds well here on a comparatively light soil, which is an additional good trait in its character.—A. C., Newark.

## ORCHIDS.

### NEWLY-IMPORTED ORCHIDS.

IN forming or adding to a collection of Orchids many people prefer to purchase newly-imported plants, and there is much to be said in favour of this. There is, of course, always a chance—if a remote one—of obtaining something new amongst a lot of Orchids that have never flowered under cultivation. But there is a much greater advantage in the way imported Orchids of all kinds grow away when introduced to a suitable atmosphere. It has often been a matter of wonder to me to see Cattleyas, for instance, recover so quickly when badly shrivelled on the journey home, while if the plants had got into such a bad way under cultivation, no amount of skill or care would have been effectual in bringing them round. There is, in short, an innate vigour in Orchids fresh from their native habitats which in many species is gradually lost under cultivation even with the best care. In selecting plants from an importation, those should be chosen that are quite dormant, with, if possible, healthy leaves, firm at the axils and fairly large, as represen-

tative of the different species. An *Oncidium* or an *Odontoglossum*, for instance, with eight or nine good pseudo-bulbs, is preferable to two plants with half that number each. When the plants arrive, the first thing necessary is a thorough and careful cleaning of all parts. All decayed pseudo-bulbs, roots or leaves must be cut clean away with a sharp knife. If only a few plants are being treated, they may then be laid upon pans filled with clean crocks, and placed in a shady position in a warm house. Where there is a considerable number a piece of stage should be given up to them, the plants being laid out thinly and sprinkled lightly with tepid water daily. If more convenient they may be suspended head downwards from the roof, and this is perhaps the most suitable treatment for *Aerides*, *Vandas* and others which, from their habit of growth, are apt to collect water in the axils of the leaves and the apices of the plants. As soon as they are showing signs of life by pushing new growths or roots they may with safety be potted, blocked or placed in baskets, as may be necessary. It is important that they be not left until the roots are far advanced, or some of these will probably be broken off in potting. The ordinary compost as recommended for established plants of the various kinds will be suitable, but it is safer to add more small crocks and charcoal, so as to ensure a quick passage for water. The plants may also be elevated rather more than usual. Great care must be exercised after potting and while the young growths of the pseudo-bulbous kinds are pushing. A little too much water, cold drip from the roof, or even an hour's exposure to bright sunshine will often cause the loss of these tiny shoots, greatly to the detriment of the plants, as back breaks are never so vigorous as the leading shoots. *Cypripediums* are easily established by potting them at once in clean crocks alone, watering them twice daily until new roots are forming, and then giving a little peat and Moss. *Phalenopsis*, too, may be successfully treated in this way, but these are best without anything in the way of compost for the first year, or with only a little fresh Sphagnum Moss to retain a certain amount of moisture. The plants must not be allowed to bear many flowers at first, even if they show, or the strongest ones will be weakened at the outset. It is a good plan with *Odontogloss* and others which produce many-flowered racemes to remove all but one or two of the flowers the first season. This will be quite sufficient to see what the variety is like, but even these must not be allowed to remain on the plants until they fade. H. R.

*Cattleya blenensis* is a charming little hybrid between *Cattleya Loddigesi* and *Laelia pumila*, in which the two kinds are admirably blended. This is at present flowering with Messrs. Williams and Son, of Holloway. It is of dwarf habit, the flowers large and of good form, the sepals and petals deeply flushed with rose. The lip, resembling that of *Laelia pumila*, is white on the side lobes, the front lobe being of an intense bright crimson-purple.

*Cycnoches peruvianum*.— This was included in the group staged by Messrs. F. Sander and Co. at the last meeting of the Royal Horticultural Society. The plant carried a raceme of several blooms, which were in size, shape and colour very similar to those of *C. pentadactylon*. The colour was a greenish yellow, spotted with reddish brown, whilst the peculiarly formed lip was white and the long arching column very prominent. A few of the species belonging to this genus are especially interesting, and are not difficult to manage provided they are treated in a proper manner. Whilst in active growth the *Cycnoches* enjoy tropical heat and plenty of

moisture both in the atmosphere and at the roots, but when the growths are complete, a cooler and drier temperature will be found to suit them best. At this time care must be taken with regard to watering.—G.

#### DENDROBIUM WARDIANUM.

This is a magnificent Orchid, which from the present time onwards will make a brilliant display. This species is annually imported in enormous quantities from India, some coming from Assam and the Khasia Hills and others from Burmah. Those from the latter district, however, have longer stems and larger blooms than those from the first mentioned, although the most highly coloured varieties appear to have originated amongst the shorter-stemmed plants from the Assam district. *D. Wardianum* was named in compliment to Dr. Ward, of Southampton, with whom it flowered soon after its introduction. It first bloomed in the Kingston Nurseries, but this plant was thought to be a variety of *D. Falconeri*, which it somewhat resembles, especially in the formation of the

Flower of *Dendrobium Wardianum*.

bulbs. The foliage falls off annually and the flowers appear in twos and threes from the joints of the leafless stems at the present season. The individual blooms often measure between 4 inches and 5 inches across and last a considerable time in perfection if kept dry. The sepals and petals are white, mostly tipped more or less with magenta-purple, and, as before stated, the smaller blossoms have the richest colours. The lip is broad and remarkable for its fine colour, being bright yellow on the disc, tipped similarly to the sepals and petals and having two large maroon blotches at the base, one on each side. In Messrs. Williams and Son's nursery at the present time are numerous forms in flower, some having the sepals and petals almost pure white. The variety named *D. Wardianum candidum* is an exceedingly rare form with pure white blossoms, excepting a yellow stain on the lip and two light reddish-coloured spots at the base. It was introduced with the original importation from Burmah by Messrs. Low, of Clapton, and first flowered in the Broad Oaks collection at Bury, in Lancashire. *D. Wardianum* enjoys plenty of heat and moisture when in active growth, but after this is complete a decided rest is necessary to ripen the bulbs and to produce

plenty of flowers. It appears to succeed best when grown in baskets and suspended near the glass, and should be potted in a compost of good peat and Sphagnum Moss, with good drainage. Having long pendulous bulbs, care should be taken to fix the plants firmly when potting, so that they do not rock about in the baskets, for if left in this condition they cannot root into the soil and become established. This charming Orchid is admirably adapted for cutting.

WM. HUGH GOWER.

#### LYCASTES.

AMATEURS and others commencing the culture of Orchids could hardly find a more suitable genus than *Lycaste* to begin with. None are easier to grow, and all of them are free-flowering and handsome plants, most of the species being also very cheap. Although they all grow with more or less freedom in the cool house, better results will be attained by giving the plants a little more heat than *Odontoglossums* and other cool house Orchids require. Shade from bright sunshine is also necessary, and an

airy, moist atmosphere at all times, except while in flower, when they must be kept drier. *Lycastes* are easily propagated by division of the plants, *L. Skinneri* being especially amenable to this treatment. They are best grown in pots, which must be clean and well drained, and the compost may consist of lumpy peat, chopped Sphagnum, and finely-broken crocks, with a little fibrous loam added for the stronger growing kinds.

The plants require an abundant supply of water at the roots during the growing season, and even when at rest they must not be allowed to get quite dry. *Lycastes* are often attacked by a soft brown scale, and sometimes by red spider if the atmosphere is at all dry.

These must be kept in check by frequent syringings with warm soapy water, care being necessary in the operation to avoid puncturing the somewhat tender foliage.

*LYCASTE SKINNERI* is the best known in the genus, and one of the most useful Orchids in cultivation. This species has many varieties, the typical flowers being bright rose on the sepals and petals, with crimson spots on the lip. By having a sufficient number of plants and growing these in slightly different temperatures, this Orchid may be had in flower for at least five months. Occasional applications of weak liquid manure are helpful during the growing season, first watering with clear water to ensure its proper distribution. The variety *alba* is wholly white, with the exception of a yellow stain on the lip. Other varieties are *debeatissima*, *nigro-rubra*, *rosea*, *purpurea*, *superba*, &c., the names of these being descriptive of their variations from the type.

*L. AROMATICA* is an extremely free-flowering species, the blossoms being very fragrant. The pseudo-bulbs are ovate, about 2 inches high, and bear two or three broadly lanceolate, plaited, light green leaves. From the base of these the single-flowered scapes are plentifully produced. Each flower is upwards of 2½ inches across, bright

golden yellow, sometimes spotted on the lip with orange-red. This species flowers at midsummer, and lasts a long time in perfection.

*L. DEPPEI*, like the preceding, deserves more attention from growers than it receives. It is similar in habit to *L. aromatica*, but the flowers are larger. The sepals are greenish yellow with abundant purple spots; the petals pure white, and the lip yellow, spotted with crimson. The variety *punctatissima* is larger than the type and a superior Orchid. The blossoms are thickly covered with purple spots and lines.

*L. HARRISONI* is a beautiful species, and quite undeserving of the neglect into which it has fallen. This frequently produces twin-flowered scapes, each flower being about 3 inches across, very thick and fleshy in texture. The ground colour is creamy white, the lip yellow at the base with purple markings. This species was referred to *Bifrenaria* by Reichenbach, being slightly different from the other kinds in habit and the formation of the flowers. This and its variety *alba* are natives of Brazil, and require more heat than the other species.

*L. LANIPES* is one of the freest flowering Orchids in existence. It is a strong grower, having pseudo-bulbs 4 inches high and leaves 18 inches in length. The scapes are one-flowered and produced in autumn. They are not very showy, being principally of a greenish white, but the fact of their lasting so well when cut is a recommendation.

*L. PLANA* is a bright and showy species and a winter bloomer. The flowers are  $3\frac{1}{2}$  inches across with bright red sepals, the petals being white, with a blotch of crimson upon the tips; the lip is roundish in front, white, spotted with crimson. This has several varieties, including the comparatively well-known *L. plana Measuresiana*, but most of them are very rare. H. R.

*Oncidium splendidum*.—This magnificent Orchid has by some authorities been classed as a variety of *O. tigrinum*, to which in the flowers it bears a strong resemblance. In habit, however, it is so entirely different, that it is difficult to believe the two in any way related. The roundish pseudo-bulbs and the thick leathery leaves of *O. splendidum* are bronzy and rough in appearance, and the spikes are produced from the base of the former. On strong plants these are frequently 30 inches in length, sometimes 3 feet. They are branched and bear a large number of flowers. The compost for this Orchid must be very free and open, as it abhors anything like closeness about its roots. I have found it do well in pots or shallow pans in equal proportions of peat fibre and Sphagnum Moss, with a free admixture of clean crocks. The pots must be exceptionally well drained, a good deal of water being required while the plants are making their growth. It must be kept well up to the light at all times, and while the pseudo-bulbs are maturing be fully exposed to the sun. The water supply must not be lessened until the bulbs have quite finished swelling, or weak flower-spikes will be the result. This is an important point too often lost sight of by growers. If they would only watch the roots of this and other Orchids during this period, and note how actively these are searching for nutriment, it would prove an instructive object lesson. Very little water is required during the early winter months, increasing the supply as the spikes develop. *O. splendidum* thrives best in the *Cattleya* house all the year round.—H. R.

*Sophranitis violacea*.—This pretty little species is not often seen in flower, and although lacking the showiness of some of the varieties of *S. grandiflora*, the flowers have nevertheless a peculiar charm. The colour is a soft purplish rose, and the blooms are produced on single-flowered scapes from the apices of the small oval pseudo-bulbs. A plant of this species was in flower recently in the collection of Captain Greenwood, of Harnham Cliff, Salisbury, where it is grown on small trellised blocks in the *Cattleya* house. It is

important that these small-growing species be kept in an atmosphere free from fluctuations of heat or moisture, or they cannot possibly thrive, the plants often becoming the prey of scale and other insects. *S. violacea* is a native of Brazil, whence it was introduced in 1840.

*Dendrobium Ainsworthii*.—This is one of the most beautiful of hybrid *Dendrobies*. The plant in growth and habit resembles *D. nobile*, one of the parents, the other being *D. aureum*. It usually flowers about the present time, and continues during February and March. The sepals and petals are creamy white, flushed with rose at the base, whilst the lip has a large central blotch of bright amaranth-purple, with numerous radiating lines of the same colour. The flowers are also sweetly scented.—G.

#### DENDROBIUM NOBILE.

I NOTED the remarks on this useful old Orchid at p. 15, and can confirm what "W. H. G." says of it. I had a large specimen plant which flowered annually at Christmas. One year it was particularly well flowered, and I counted 1400 blooms on it. This happened twenty years since, and the blooms at that time were worth 3s. per dozen. The plant was broken up into a score of smaller pieces, and I have them now, but instead of having one plant in flower at Christmas I have two or three smaller plants, and a succession of bloom is kept up until June. In fact, I have had specimens from that same plant in first-prize collections in London in that month. This is evidence of the vigorous constitution of the species, for this collection of a score of specimens was one small plant in a 5-inch pot thirty-two years ago when I took charge of it. There are other *Dendrobiums* quite as beautiful or even more so, but none of them would stand culture of this kind and increase to the same extent. The idea still exists, not only amongst amateurs, but even amongst gardeners, that it is necessary to have a special Orchid house before any Orchids can be grown. I can remember the time when Orchid houses were practically unknown, and yet what fine specimens were grown of this *Dendrobium*, *Cattleya Mossii*, *Laelia purpurata*, *Phajus grandifolius*, &c., with little aid except the vineries or other forcing houses.

*Dendrobium nobile* requires a growing season, when the temperature must be high to obtain good results, and after that a time of rest. The plants flowering at Christmas should be placed in a temperature of 60° to 65° as a minimum as soon as they pass out of bloom in order to get the growths matured early, and as the succession plants go out of flower they must all pass through the same treatment. All that the gardener has to do is to keep them well supplied with water and in a moist atmosphere while growing. If they push out growths and roots freely from the tops of the stems it is a sign that something is wrong with the roots; either they are not receiving enough water, or the roots have got into bad condition by the decay of the potting material. It is a good time to re-pot any plants that need it when they pass out of bloom, but do not over-pot. This is an error which many anxious cultivators are liable to commit. The pots are filled nearly half-full of large pieces of broken pots, well placed; over the drainage I place a layer of Sphagnum Moss and complete the transfer of the plant by getting it out of the old flower-pot with as little injury to the roots as possible. When the roots have laid hold firmly of the inner surface of a flower-pot it is better to break the pot to pieces and remove it bit by bit than destroy half the roots. The compost should be fibrous peat torn to pieces and the finer particles sifted out; add to it a liberal proportion of freshly-gathered, cleanly-washed Sphagnum Moss and clean potsherds. Pot firmly and always raise the plants above the surface in the form of a cone. This is the treatment most of the *Dendrobiums* receive, from the small-growing species with stems an inch high to the more gigantic specimens, such as *D. Dalhousianum*,

with 6-foot stems. Some, of course, do better in baskets; indeed, most of them will succeed as well in baskets as in pots. The best grown plants of *Dendrobium nobile* I ever saw were in the garden of Viscount Portman, Buxted Park (gardener, Mr. Prinsep). The plants are cut down annually, and each year new growths are made, all the flowering growths being cut away. Those who try this plan must remember that this *Dendrobium* makes its growths one season and the flowers are produced from those growths the following year. All Mr. Prinsep's plants were grown and flowered in large teak baskets.

J. DOUGLAS.

*Calanthe Textorei*.—This fine species belongs to the *veratrifolia* section. It is an evergreen plant, and will succeed in a much cooler temperature than the deciduous kinds. It should be grown in large pots and given plenty of water whilst in active growth. The flowers, produced on a stout erect scape, which grows to a height of from 18 inches to 2 feet, are pure white, the petals and lip being shaded with pale mauve when first expanded. This plant is a native of Japan, whence it was imported about eighteen years ago by Messrs. Veitch, of Chelsea.—W. H. G.

*Sophranitis grandiflora*.—I have noted this plant flowering well in many collections during the winter, especially in the neighbourhood of London. Its bright scarlet blossoms make a striking and pleasing contrast to those of other Orchids which may also be in bloom. It may be grown either upon a block of wood or in a small basket, but the best results I have noticed have been where shallow pans suspended close to the glass are used.—W.

#### LAELIA SUPERBIENS.

This is a noble species when well grown, and although small plants do not as a rule flower freely, when once these attain a good size there will be no cause for complaint on this score. The pseudo-bulbs are each about 18 inches in length and bear on the apex a pair of deep green leaves. The spikes proceed from between these, and are each from 4 feet to 5 feet in length, although naturally they are said to grow to 10 feet or 12 feet. The flowers occur in loose umbels on the tops of the spikes, as many as sixteen not being uncommon on strong plants. The sepals and petals are rosy-pink, the lip deeper in colour, streaked with golden-yellow. *L. superbians* requires liberal treatment to grow it well. The pots should be large enough to take the plants easily, as the roots are strong and seem inclined to ramble in search of nutriment. The compost should be open, but substantial, and I have had good results from the use of partly-decayed leaf mould in equal proportions with peat, broken into lumps as large as a walnut, and Sphagnum Moss. Plenty of charcoal must be added, and if it can be procured, some rough pieces of burnt clay or ballast, as it is termed at the potteries. This material is very suitable for use in large pots or baskets, as it is very porous and not so liable to injure the roots as the sharp-edged potsherds. This species enjoys a slightly higher temperature than most of the genus, and does well in the company of *L. purpurata* and others in a spacious house where plenty of head room can be afforded it. It will not thrive in a low, close structure with its head nearly touching the glass. Sometimes, owing to the vigour of the leading growths, large plants get bare towards the centre, and when this is the case the rhizome should be notched half way through between the second and third pseudo-bulbs in order to induce the dormant eyes to start into growth. This improves the appearance of the plants without in any way interfering with the full development of the leading growths, which if the rhizome was cut right through would probably sustain a severe check. *L. superbians* is a native of Guatemala, where it was discovered more than half a century ago by Mr. G. Ure-Skinner.

## STOVE AND GREENHOUSE.

## THE CHIMNEY BELLFLOWER.

(CAMPANULA PYRAMIDALIS.)

This handsome species of the Bellflower family is a European plant, having been introduced into this country more than 350 years back; hence it is fully entitled to be classed as an "old-fashioned plant." It stands out still as one of the very finest of its race in every respect, being an easy plant to grow, a most prolific flowerer, and a very showy one when in bloom, lasting also for a length of time in that state when well managed. The culture of this *Campanula* was probably more popular before glass houses came so much to the front, being a subject easily kept through the winter with a little protection if possible, it being certainly more secure if this be accorded, although in favoured positions it may be wintered in safety on sheltered borders. It is, however, as a cool greenhouse or conservatory plant that its beauties are brought out in their best character, and as such it can be recommended for extended cultivation even in these days, when other attractions are much more numerous than of yore. The subject of the illustration is an example of what may be accomplished under good culture, thus making essentially a specimen plant of no mean attractions. It is taken from a plant of the pure white variety with larger flowers than usual. For quite cool houses of any aspect the Chimney Bellflower can be strongly recommended as a most useful flowering plant, coming into bloom about the middle of July and lasting until the end of September. I have had the same plants good for this period by continuously picking off the seed-pods; unless this be followed up the later flowers will not develop, as all the strength seems directed towards the swelling of the seed-vessels. At the base of the stalk of each flower others in the embryo stage may be noted, and these will be repeatedly reproduced until the plant is finally exhausted if the seed-pods are not allowed to swell. Honey-bees are particularly fond of this *Campanula*. I have noted them by hundreds very busy at work; hence probably more pods swell than would otherwise do so. There are various modes of

## CULTURE

that can be adopted according to circumstances. If plants of large size be wanted, such as will produce from fifteen to twenty or more spikes, these reaching a height of 7 feet or more, then it is best to sow the seed in August in a cold frame and winter the plants afterwards in 3-inch pots, these being potted about the following March into one or two sizes larger, according to their vigour. Early in the summer another shift should be given

them, and early in September the final or flowering shift, which, in the case of strong plants, will be 10-inch or 12-inch pots. I have seen them in larger pots, but the gain does not correspond with the amount of labour expended. These sizes are quite large enough for wintering the plants in in cold frames; larger would be cumbersome. These plants will be fit for standing

gentle warmth, gradually hardening off, until cold frame treatment will suffice when well established after pricking off. These plants should not be stood out-of-doors fully exposed until established in 4½-inch pots, and then it will be better to plunge them, so as to avoid any undue amount of watering. These plants will take two shifts before the following winter if well cared for. In any case a late shift should not be given, otherwise the plants will not have time to re-establish themselves before winter. I much prefer to give the final shift in the autumn, but if room for storing in cold frames be limited, then the final shift may be given when the plants are stood outside in the spring. From the time of seed-raising onwards avoid overcrowding, pricking the seedlings off for the first time, as in the case of Celery, quite early and in shallow boxes. Firm potting is very essential, it being productive of a sturdier and more compact growth. The chief factor as regards soil is good loam, road scrapings being a good addition thereto in lieu of sand. I do not advise any free use of manure in the soil; some small amount of well-decomposed leaf-mould or of spent Mushroom manure would be ample. Later on when the spikes are advancing an occasional application of an artificial stimulant or of liquid farmyard manure will greatly benefit the plants. In no case, however, should excessive watering be indulged in; it must rather be guarded against, as prejudicial to the plants, more particularly when coming into flower. If this point in their culture be not attended to, the plants will cast their foliage prematurely, being denuded of leaves at the base, thus looking lean and meagre. The best method of support, which can scarcely be dispensed with, is slender Bamboo sticks painted green. By the use of these in a moderate manner there will be nothing unsightly. It will be well, however, to do the staking twice: first as supports in a temporary manner during growth, otherwise the shoots, by reason of their very rapid development, will split away at the base, and, secondly, just prior to the first flowers opening.

Having secured a specially good strain of seedlings by selection, it is well to stand aside the best of these for seeding, only allowing the finer flowers to produce seed. If it is desirable to propagate particular varieties by themselves, it can easily be accomplished by the roots, as in the case of Seakale by sets. This mode of increase should be attended to as soon as

the plants go out of flower, making the sets as in the case of Seakale, they being smaller of course. These should be covered with silver sand for a few days to stop any bleeding, and then they can be pricked off into boxes and put into cold frames. The selection made by Mr. Wythes, of Syon House, is of dwarfier growth with stout spikes, bearing the flowers well down to the base;

The Chimney Bellflower (*Campanula pyramidalis compacta*). From a photograph sent by Mr. J. Hudson, Gunnersbury House, Acton.

out-of-doors by the middle of March with a little shelter, it being a good plan to plunge them straight away in eider ashes up to the rims. This, in fact, is the best way to winter them in the frames, so as to protect the pots from breakage by frost. Another plan by which some amount of time is saved, as well as a

wintering in frames, is to sow in February in a

the individual flowers are large and show considerable variation in colour. This is known as the "compacta" strain or Syon House variety.

The plant from which the photograph of the plate was taken was only 3 feet 6 inches in height from the pot. PLANTSMAN.

## FERNS.

### VARIEGATED FERNS FOR THE WARM HOUSE.

ALTHOUGH, generally speaking, Ferns requiring stove temperature are not considered as useful from a decorative point of view as their congeners of a hardier constitution, the list of their variegated forms contains some equally well-marked plants, some of which are of easy culture, and I may also add that most of them possess decorative qualities to a very high degree. If we take the genus *Adiantum*, we find several nicely variegated forms, the most remarkable amongst them being undoubtedly the beautifully coloured *A. macrophyllum albo-striatum*, a somewhat cumbersome name for such a very handsome plant. It is an extremely pretty form which, according to reliable information, appears to have made its appearance simultaneously in England, in France and in Belgium some ten years ago—an occurrence which can scarcely be accounted for in any way. In each case the variegated plant has preserved the erect, somewhat rigid habit of the typical species, and the fronds, rising from an underground creeping rhizome, attain from 12 inches to 18 inches in height. Their large and peculiarly-shaped leaflets are, like those of the type, of a delicate pink or red colour, which eventually attains a crimson hue; but they are irregularly, but abundantly striped with white, which variegation, besides being the principal ornament of the partially developed fronds, remains perfectly distinct and prominent when the foliage has assumed its permanent bright green colour. Some grand specimens of this lovely Fern were exhibited by Messrs. J. Veitch and Sons at the Temple show last May, when the pleasing mixture of the colours was much admired.

*A. cuneatum variegatum*, a plant sent out some two years ago by Messrs. Pitcher and Manda, is certainly distinct in itself, but it is questionable whether the variegation, although well marked, is sufficiently conspicuous to add to the decorative value of the plant, which, by its loose habit and the slender nature of its fronds, reminds one much more of a variegated form of *A. elegans* than of the popular Maiden-hair Fern. A much better form of *A. cuneatum* with variegated foliage made its appearance in 1871 among the thousands of seedlings which were then annually raised in Messrs. H. Low and Co.'s nurseries at Clapton, for in those days *A. elegans* was not known. In this case the variegation was exceptionally good, the very dark green colour peculiar to the mature fronds of the species being copiously relieved by pure white streaks, which extended to all parts of the little fronds. Unfortunately, that most interesting and very promising plant was, through neglect, lost to cultivation and to the floral decorator. Instead of being separated during the process of pricking off, three or four seedlings had, as is frequently the case, been allowed to remain together, and one day the plant with the variegated portion in it was found to have disappeared among a quantity of young *A. cuneatum*, which had been disposed of for decorative purposes. This occurrence is all the more to be regretted, as the reproduction of the plant would have been watched with the utmost interest. Should another such form make its appearance spontaneously now, it would most likely be carefully preserved and be propagated by the division of the crown, if not from spores. In

*A. CLAESIANUM* we have a new variegated Fern, which is also a valuable acquisition. It was introduced from Brazil and exhibited at the Temple show last May by M. Linden, of Brussels (who named it after his collector, M. Claes, who discovered it), when it was much admired by all who saw it. Its growth is compact and tufted; its fronds, about 9 inches long, are composed of rhomboid pinnules of comparatively large dimensions, of a pale green colour, ornamented with a silver blotch at the base, from whence numerous silver lines radiate to the margins, which are bluntly toothed. It is stated that it reproduces itself perfectly true from spores. It is, however, in the genus *Pteris* that the most useful as well as the most striking Ferns requiring stove temperature are found. As regards beauty and richness of colour, there is no other variegated Fern which can bear comparison with

*P. TRICOLOR*, one of the most charming Ferns ever introduced into cultivation. According to Lowe ("New and Rare Ferns," t. 9), who describes it as "being graceful in habit, elegant in form, moderate in size, and splendidly variegated with green, white and red, well contrasted," it was introduced from Malacca by M. Linden. Although this really handsome plant has been known in collections for upwards of thirty years, it is only now and then that we hear of someone having succeeded in growing it to perfection, and in most cases this happens seemingly without anything special in the way of cultivation. Its well-being evidently depends more on local or climatic influences than on skilful treatment. As a proof of this, it may be stated that in some places where formerly this beautiful Fern was thriving it will now hardly grow, in spite of unchanged treatment; whereas, in other places, where for years it only contrived to exist, it occasionally makes a sudden burst and for a season or so grows apace. In the form and habit of this plant it resembles *P. aspericaulis* so closely as to leave no doubt as to its being a variegated form of that Fern, from which it is distinguished principally by the brilliant colour of its fronds, which sometimes attain 2 feet in length. These when young are of a purplish red or bright rose colour, and when mature their leaflets are of a vivid dark green at their edges, while their basal part is silver-grey, their midrib being of a permanent bright purplish colour. The diversity of colours in the fronds in different stages of development at the same time on each plant greatly adds to its beauty. If

*P. ARGYREA*, also introduced from the East Indies by Messrs. J. Veitch and Sons, lacks the extreme brilliancy of the fern above described, it may, on the other hand, claim to be perhaps the most useful of variegated Ferns where size is of some consideration. It is by far the more useful of the two East Indian forms and is particularly well adapted for pot culture for decoration, its gracefully arching fronds under liberal treatment frequently exceeding 4 feet in length. On account of its remarkably well-defined and striking variegation it is most effective, as the large band of silvery white in the centre of its fronds and leaflets forms a most pleasing contrast with the lively green by which it is surrounded in every part of the plant. Although sometimes recommended for growing in a cool house, where it thrives very well during the summer, this useful species evidently requires a higher temperature during the winter; its dislike to cold is clearly indicated by the brownish colour which its fronds, even when mature, assume under cool treatment in winter. Another very prettily variegated form of *Pteris* sent out by Mr. Bull some four or five years ago under the name of

*P. VICTORIAE* has all the appearance and is said to be exactly the same plant as *P. ensiformis variegata* of Moore, exhibited at one of the meetings of the Royal Botanic Society as far back as June, 1877, when it received a first-class certificate. It is a remarkably slender and graceful plant of small dimensions, producing two entirely distinct sorts of fronds, the barren ones being few in number, small and prostrate, while the fertile ones, up-

right and abundant, are 12 inches to 15 inches long and composed of narrow leaflets about a quarter of an inch broad. They are particularly attractive on account of their silver markings, which are conspicuous throughout the plant. Although it reproduces itself freely from spores, this Fern is given to variation, and some of the seedlings raised from it are thoroughly distinct; thus, for instance, is May's.

*P. REGINE*, which is of much more vigorous constitution, and in which the variegation runs in narrow stripes to the margins of the leaflets, showing very little, if any, of the green border noticeable in *P. Victoriae*. *P. Regina cristata*, also raised in Mr. May's nurseries at Edmonton, is another form with beautifully and distinctly variegated foliage of a more slender nature and very elegant habit on account of its fronds being very prettily and regularly crested.

*P. NOBILIS*, or, as it is more commonly called, *Doryopteris nobilis*, is another handsomely variegated Fern requiring stove temperature. It is a native of Southern Brazil, and, so far as general appearance is concerned, totally different from other *Pterises*. Its fronds, borne on naked, wiry stalks, vary considerably as regards shape and size, according to the age of the plant on which they are produced. In its young state it only produces single, heart-shaped fronds, and the next ones are sagittate or arrow-shaped; while these eventually developed are halbert-shaped and finally somewhat palmate in form, with the terminal and the upper lateral leaflets entire and the lower lateral ones divided into two or four spear-shaped segments on their lower side. They are of a bright green colour, and their broad, slightly undulated segments are ornamented throughout their centre with a broad white band, which gradually diminishes in intensity towards the edges.

To the above list of variegated Ferns may also be added the variegated forms of *Selaginellas*, as they are closely related and thrive under the same treatment. Besides the golden and the silver forms of the common *Selaginella*, respectively called *S. Kraussiana aurea* and *S. K. variegata*, which during the winter require to be kept close to the light in order to prevent their damping off, the most popular, the most useful and the best known is *S. Martensi variegata*. This variety has retained the habit and vigour of the typical plant, which is of erect habit, but the dark green leaves which clothe the succulent stems, which on their underside produce a great quantity of roots, are profusely blotched with creamy white—a character which, though not quite constant, is readily reproduced by means of cuttings, which root freely in a light porous soil and a warm, moist atmosphere. DOODIA.

*Polypodium (Phlebodium) aureum arcuatum*.—Where cut flowers are in demand and a glass accommodation somewhat limited, there is often at this time of the year a great strain on the resources, which can only be met by growing such things as last well in a cut state. Foliage, too, must be provided in plenty, as the open garden will not now give much variety in this way. Ferns are largely grown for the purpose, and most of them associate well with cut flowers of any kind, their worst fault being a tendency to wither quickly. A most useful kind (especially for large vases) which has not this fault is the one named above. Fronds of this which were cut more than three weeks ago are now looking as fresh as when cut. The glaucous hue on the foliage shows up well under artificial light, the fronds looking quite silvery and distinct from any other thing we have. This Fern is quite one of the easiest to grow, as it is not at all fastidious as to soil. Given plenty of drainage and plenty of water, good fronds and plenty of them will be forthcoming. Like most of the *Polypodiums*, growth commences late in the season and the

plants are at their best in mid-winter, which is a great advantage. Anyone wishing to add to his stock of useful winter fine-foliated plants could not do better than get a few plants of this if not already in stock.—J. C. TALLACK.

## NOTES OF THE WEEK.

**Snowdrops.**—It is worthy of notice how much later these are coming into bloom this year than last. Three years ago I had them in full bloom at the end of January, but now (January 26) they are only just showing flower. On a shallow ledge where they generally come early they are equally late. I think this arises from the cold summer.—J. CROOK, *Forde Abbey*.

**Water Hawthorn.**—The slight frosts we had in October did not seem to check the blooming of this interesting water plant, fresh flowers appearing until a few days before Christmas. *Aponogeton distachyon* does best when planted in about 2 feet of water, and if it can be placed where the water enters the pond it will do much better and have a better chance of not being frozen.—J. W. H.

**The Genevan Plant Protection Society.**—I said in my last letter that I would not answer further letters of Mr. Leonard, and I will keep my word. Readers of THE GARDEN who would like to have an answer about these letters will find them in our next "Bulletin de l'Association pour la Protection des Plantes," which will appear this month or in the beginning of March, and which will be sent to anyone who asks for it.—H. CORREVOX, *Geneva*.

**Rosa moschata nivea.**—In his account of *Rosa moschata nivea* "A. H." says that as to its origin and history he can give no information at all. In the *Botanical Register*, vol. x., 861, he will find a good plate of it, with its full history, by Dr. Lindley. It is a beautiful Rose, and easily propagated by cuttings. I have had it for many years. It is not in the Kew list of Roses, but I believe they have it.—HENRY N. ELLA-COMBE.

**Helleborus colchicus Zenith.**—I do not know if the above variety of *H. colchicus* is grown in many gardens. If not, it would make a beautiful addition to the early spring flowering plants. It is quite a distinct form, and much earlier than any of the Lenten Roses. Since the first week in December flowers of the above have been plentiful. Although the stems were short when the first flowers developed, they are now 6 inches or 8 inches in length, with several well-expanded flowers on each. The colour is a very rich purple; the petals inside look as if they are lined with velvet, the centre having a large cluster of cream-coloured stamens, which add to the beauty of the flowers.—J. W. H.

**Olearia Haasti.**—In THE GARDEN of January 12, and also of January 26, much has been said in favour of this most useful and ornamental shrub. While cordially supporting all that has been said in praise of this plant, I should like to point out an additional good quality not mentioned by your other correspondents. *Olearia Haasti* is one of the few flowering shrubs that will thrive beneath the shade of other trees, and I have frequently seen it succeed in places so densely shaded, that even common Laurel would not grow. It flowers late in the season, when the blooms of spring-flowering shrubs are past, and is all the more valuable on that account. When planting shrubs beneath the shade of trees we generally fall back on Aucuba, Holly, Yew, Laurel, and such like, and an evergreen flowering shrub, such as *Olearia Haasti*, will be welcomed, especially as its flowers appear at a season when there are comparatively few shrubs in bloom.—F. W. MEYER, *Exeter*.

**A note from Oregon.**—Our old friend Dr. Bolander writing to us under date January 10

from Portland, Oregon, says: "The immediate environs of Portland are not rich in plants, but the regions of the mountains near by certainly are. From any small elevation of this town (of 75,000 inhabitants) we have in sight the snow-capped mountains: Mt. Hood, 12,000 feet to 13,000 feet; Mt. Adams about the same height, Mt. St. Helens and Mt. Rainier. I am told that Mt. Adams and Mt. Rainier are very rich in curious plants. Mt. Hood is not, neither on its east nor its west side, for I ascended both. The environs of this city are grand. Besides the mountains we have in the city the navigable river Willamette, joining the great Columbia 13 miles below here. The most of the land is still covered with large coniferous forest trees, Douglas Spruce predominating. The southern part of this State has more the make up of Northern California. We had a catalogue of plants of the entire State by Thomas Howell, but it is now out of print. The author is now working at a flora of this State. I am now an old man, unable to go much about, but still I cultivate many plants in a small garden to while away my leisure time. A few words on climate. Our winters are in the main very short. Snow 1 foot to 2 feet only in some winters, like the present. Tea Roses hardly ever freeze. Rain a good deal till June, but not thirteen months, as our enemies say. During July till September often not a drop of rain falls. This is a pity. The summer heat is not great, the nights being cool."

**National Chrysanthemum Society.**—In addition to the three exhibitions announced to take place at the Royal Aquarium in October, November and December, the usual show of early Chrysanthemums, Dahlias and Gladioli will be held on September 3, 4 and 5, the National Chrysanthemum Society giving £20 in prizes for early Chrysanthemums, and £10 towards the Dahlia and Gladioli classes, supplemented by a grant of £50 from the Royal Aquarium Society. The schedule of prizes will be issued, as heretofore, with that of the National Chrysanthemum Society.

**The Gardeners' Orphan Fund.**—A meeting of the executive committee took place at the Hotel Windsor on the 25th ult., Mr. William Marshall in the chair, there being, as usual, a large attendance of members. The secretary, Mr. A. F. Barron, announced the following special donations: From Mr. M. Todd, seedsman, Edinburgh, sale of flowers, £13 10s.; Mr. H. J. Jones, Rycroft Nursery, Lewisham, visitors to his display of Chrysanthemums, £9; the Midland Carnation Society, Birmingham, per Mr. R. Sydenham, £5; Mr. J. Kipling, The Gardens, Knebworth, skating on the lake, £2; Mr. H. Herbst, Kew Road, Richmond, £1 1s.; Mr. W. H. Divers, The Gardens, Belvoir Castle, Grantham, 8s. 4d. From boxes: Mr. William Marshall, Auchincraigh, Bexley, £1 7s. 10d.; Mr. J. Hughes, Harborne, Birmingham, £1 3s. 3d.; Mr. G. Fry, Lewisham, £1 1s. 10d.; Mr. H. Perkins, The Gardens, Greenlands, Henley-on-Thames, 10s.; also a number of small sums, also from boxes, and all equally welcome. The secretary brought up a draft report and balance-sheet of a satisfactory character, considering the general depression in business. They were passed for presentation at the annual general meeting on February 8, at which Mr. Harrison, of Leicester, will preside.

**The weather in West Herts.**—A very cold week. On the coldest day (Monday) the temperature in shade at no time exceeded 30°, and during the following night a thermometer exposed on the surface of the snow indicated 25° of frost, or a lower reading than any previously recorded during the present winter. A similar reading was also registered on Tuesday night. At 2 feet deep the temperature of the ground is now within 4°, and at 1 foot deep within 2° of the freezing-point. During the past month there have only been seven mild days and the same number of mild nights. Taken as a whole, it was the coldest January I

have yet recorded here, my observations dating from 1885. The mean temperature of the soil was also low, being at the depth of 1 foot 1° below the January average for the previous nine years. Rain or snow fell on no fewer than twenty-two days, and to the total depth of 3 inches, which is rather more than a quarter of an inch in excess of the mean for the month. There were three distinct falls of snow. On the 13th the ground was covered to the depth of 3½ inches, on the 22nd to the depth of 2½ inches, and on the 28th it was 1½ inches deep. Besides being cold and wet this was also an unusually gloomy January, the average record of sunshine only amounting to about an hour a day. Another feature of the month was the great predominance of north-westerly winds; indeed, for altogether 432 hours, or eighteen days, the direction of the wind has been some point between west and north.—E. M., *Berkhamsted*.

**What's in a name?**—While thoroughly sympathising with the dislike felt by some of your correspondents to the many plant names that are uncouth and very long, we ought to remember that there is the other side of the question. If we want to correspond or share information with Continental friends, I fear that Virgin Bower, Bald Money, Avens, Almond Cross, and other excellent British names might not avail always to identify our plants. The constant revision and division of generic names is a sorrow in all branches of natural history. It would seem as if sub-genera might meet the case in many instances without disturbing names well known and understood. Then as to specific names, it would indeed be a gain if a little self-restraint were practised, especially by some German and Russian botanists, so as to avoid, for the sake of weaker brethren, such stumbling-blocks as *Kolpakowskiana*, *Szovitzianum*, *Tschibatchewi*, and the like, memorials no doubt of dear and honoured friends, but striking us as somewhat offensive. Though as to this, too, we perhaps look at the matter from an insular point of view, for an attempt to pronounce our surnames might prove an equally stiff obstacle to them. As to the myriad hosts of florist flower names, no doubt there is a very natural feeling in their authors of pride and satisfaction which leads them to associate a novelty with some beloved member of the domestic circle or some generous patron, and being a very human tendency it is likely to continue.—F. L. S.

**Plants wanted.**—Perhaps some of your readers can tell me where a good strong clump of *Lathyrus magellanicus* (true) can be had. I have searched many catalogues and cannot find it. I also want seeds of *Dipacis sylvestris* or *lacinatus*. I suppose seed-men think *Teasels* too common for their lists, but none grow wild in the north, and I want them for a bit of wild gardening.—M. P. FORSTER, *Corbridge-on-Tyne*.

"This is an Art  
Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHIDS.

### NOTES ON ORCHIDS.

THE lengthening days herald a period of increased activity among Orchids, and all arrears of winter work, as cleaning and preparing composts, should be completed without delay. Deciduous *Calanthes* as they go out of bloom should be placed on a dry shelf in a warm house in the pots in which they have been grown. No attempt should be made to start them until they break naturally, when they may be placed at once in their flowering pots, starting in small pots being quite unnecessary. Many *Cypripediums* may now be potted—in fact any not being in flower that require it. Equal parts of peat, chopped Sphagnum, and fibrous loam, with plenty of charcoal and small crocks, will suit the stronger growing kinds, while for those of weaker growth less loam should be used, and some rough pieces of limestone added or used in place of crocks for drainage. Other strong-growing semi-terrestrial Orchids, as *Anguloas*, *Peristeria*, and *Phaius*, may as soon as signs of new growth appear be repotted, using a compost similar to that for the strong-growing *Cypripedes*, enriched with a little dried cow manure. Especial care must be taken with the drainage of all these Orchids, as they require so much water when growing. In potting, remove all decayed roots with a sharp knife and all sour portions of the compost. Beginners in Orchid culture are apt to be afraid of burrowing with the hands among the roots for this purpose, but this is a mistake, as if carefully treated afterwards no harm can accrue from this; whereas if the soured compost and half-rotten roots are allowed to remain, then decay soon spreads to the sound and healthy portions. The temperature of the *Cattleya* house must now be slightly increased, and the atmosphere kept proportionately moist. Where such as *C. Trianae* and *C. Schroederi* are in bloom, care must be taken that no water touches the flowers, as this soon spots them, greatly marring their beauty. Late plants of *Dendrobium nobile* and others must not be kept too moist, as until the flower-buds can be distinctly seen there is always a danger of their producing growths instead. Those *Dendrobes* that are naturally late in finishing up their growth, as *D. macrophyllum* and *D. Dalhousianum*, should be encouraged to grow as early as possible, in order that the new pseudo-bulbs may ripen with the waning sun in autumn. Plants of *Lælia anceps* as they go out of flower may be repotted if necessary, but this ought not to be oftener than once in two or three years, provided some of the surface compost is removed annually and a little fresh substituted. In repotting set the leading growths as far as possible from the rims of the pots and bed the compost firmly. Keep a sharp look-out for yellow thrips on *Masdevallias* coming into flower, as they soon ruin the appearance of the flowers if not kept under. The roots of these Orchids are now very active and they must not be allowed to get dry. Green fly is also beginning to be troublesome both among these and the advancing spikes of *Oncidium*s and *Odontoglossum*s. If these are daily looked for and removed with a slightly damp sponge, there will be no need of fumigating, but a little

tobacco powder or sulphur may with advantage be dusted lightly about the young growths. *Odontoglossum citrosum* must be kept quite dry at the roots until the flower-spikes can be seen in the points of the young growths. It does not matter if the pseudo-bulbs shrivel, as they quickly plump up again if watered as soon as the spikes are visible. A light position at the cool end of the *Cattleya* house suits this Orchid at this season. *Vandas*, *Aerides* and similar Orchids must, as soon as they are seen to be on the move, be top-dressed with Sphagnum Moss. If there is the slightest disposition to souring, let all the old Moss be picked and washed away, all decayed roots cut off and the sound ones relaid among new material, covering as many as possible of the air-roots at the same time. Keep all glass, stages and pots clean, have the houses washed out daily, and sprinkle a little soot and lime under stages and in out-of-the-way corners. Small pieces of Potato or Carrot laid about in the evenings and examined every morning make good traps for woodlice and small snails, which must be diligently kept under, or they will work much mischief among the young roots and tender growths. H. R.

**Angræcum Leonis.**—Of this singularly distinct species there is a large stock in one house at St. Albans. These plants are unusually vigorous, with the characteristic fleshy leaves of large size, the aerial roots being correspondingly abundant. This species with its large sweetly-scented blossoms of the purest white is one of the best of all Orchids in cultivation for bouquets, sprays, &c. For this purpose its flowers would undoubtedly be much sought after by florists if it were more plentiful. What a contrast is afforded in one genus between such as *A. Leonis* and *A. sesquipedale*, *A. citratum* and *A. eburneum*!—*ORCHIDS.*

**Pilumna nobilis.**—The older variety, *Pilumna fragrans*, is the better known, or rather more plentiful species, but *P. nobilis* is much the better variety. I was told the other day by a good Orchid grower that the sweet-scented *Pilumnas*, or *Trichopilias* as they are now called, degenerated in a few years after a course of treatment in our hothouses. This degeneration is caused, I believe, through growing the plants too warm. The *Cattleya* house is too warm for them, as I find the plants succeed well year after year if grown in the cool house along with the *Odontoglossum*s, the pseudo-bulbs finishing up to a large size. Another mistake is through over potting. If potted at first in a well-drained pot, using the best fibrous peat, the plants need not be disturbed for three or four years unless the compost has become sodden. The rooting material only requires to be kept fairly moist whilst the plants are growing. After growth is finished only give enough water to keep the plants plump.—*A. YORKE.*

**Cypripedium species at St. Albans.**—These are, like the hybrids, grown in immense quantities, no opportunity of adding to the collection being lost. Many of these are species that have been imported direct from their native habitats; but whether this be the case or not, all are in most luxuriant growth, finding evidently a very congenial home in the light, low span-roofed houses. *C. Chamberlainianum* is represented by some very fine, healthy, well-established plants, some of which are just coming into flower, and, considering the fresh condition of the plants, the best possible results should obtain. There is one remarkable feature about the flowers of this distinct species which I had not noted until my attention was drawn to it by Mr. Maynard. It is in the twist of the petals, the right petal turning under and the left over; this appears to be a fixed character of this variety. There is at the present time a very fine stock of *C. Dayanum*, which for the sake of its beautifully marked foliage alone is worthy of a place in any collection. It is

beyond doubt the best of any in this respect, the pure silvery mottling standing out in such contrast to the pale green. I recollect well seeing this *Cypripedium* in Mr. Day's collection at Tottenham at the time of its introduction. The montanum vars. of *C. insigne* are plentiful and so very distinct. *C. villosum aureum*, in its true character, and *C. villosum Colossea*, with extra large bold-looking flowers of deep colour (a very fine form), were both good. *C. callosum* and *C. Spicerianum* were both in flower, the latter being a superior variety. *C. Sanderianum*, which belongs to the *Selenipedium* section, is a distinct species, with elongated petals and a pointed lip; its influence will no doubt be apparent before long in the hybrids. Most of the true *Cypripediums* at St. Albans are grown in the span-roofed houses already noted, but those of the *Selenipedium* type are chiefly to be found in the long corridor-like structure.—*ORCHIDS.*

**Cattleya Trianae.**—The flowers of this fine spring-flowering species are now commencing to open. The first flowers I have seen this year were in the Victoria Nurseries, Holloway, where the species is largely grown and well represented by both light and deep coloured varieties. This plant belongs to the *labiata* section and is a native of New Grenada, from whence it was imported many years ago. It has become very popular in our gardens, and enormous quantities are from time to time sent home. This species varies considerably in the colour and markings of the blooms, and during recent years some most beautiful kinds have received varietal names.—*W.*

**Cypripedium purpuratum.**—I recently noticed this very distinct and pretty species in flower. It is a very interesting plant, and is easily distinguished from all others in cultivation. It appears to be getting scarcer each year. It is also stated to have become exceedingly rare in its natural habitat in Hong Kong, and it is to be hoped that it will not eventually die out entirely. It was amongst the first known kinds to be introduced to our gardens and has been used by the hybridist with excellent success. Such beautiful hybrids as the following claim *C. purpuratum* as one of their parents: *C. H. Ballantine*, *C. Maynard*, *C. Cyathea*, *C. Edith Winn*, and several others.—*W. H. G.*

**Cypripedium insigne varieties.**—From "W. M." comes a box containing flowers of this old favourite, Nos. 1 and 2 being the beautiful variety *punctatum violaceum*, or, as it is often called by the Continental growers, *Chantini*. No. 1 is a nice coloured form, and "W. M." says the plant is carrying over forty of these fine blooms. No. 2 is a rather paler flower of the same kind. The other two blooms arrived in poor condition, the box having been broken in transit. No. 4 appears to be the variety *C. i. Maulei*, and possibly No. 3 may be *C. i. Wallisi*, but without flowers in good condition it is impossible to name varieties of this species. At the present time so many have received varietal names, that it becomes an almost impossible task to identify one from the other, excepting in the most distinct forms. I should like to see Nos. 3 and 4 again.—*W. H. G.*

**Cymbidium Lowianum.**—This Orchid appears to be unusually good this season, the spikes on many plants I have seen being especially fine and the growths very strong and healthy. When there is room for them the different species belonging to this genus are very attractive either in or out of flower, and, lasting as they do for many weeks in perfect condition, are very useful in keeping up a show of flower. This does not distress the plant to any appreciable extent, as in the case of *Oncidium*s, *Odontoglossum*s, and others. Those commencing the culture of this Orchid should procure strong established plants, as these are far more likely to do well than newly-imported species, especially if they have suffered much in transit. The compost best suited to its requirements is three parts of good sound peat to one of fibrous loam, using this in a rough state, and adding thereto a little chopped Sphagnum

and plenty of charcoal or broken crocks. The pots may be fairly large, as plants in good condition grow rapidly, and the drainage must have special attention. The roots of this Orchid are stronger and more persistent than those of some others: therefore, in repotting they should not be disturbed more than is absolutely necessary. Of course, no Orchid roots like disturbance more than those of any other plant, but with some of these it is a necessity, as they do not wrap and hold the compost together in the way of those of *C. Lowianum*, and in consequence some parts get sour and must be removed. The best time for repotting is as soon as possible after the flowers are past, and the plants must be encouraged to grow strongly by placing them in the warmest part of the Cattleya house and keeping them moist both at the roots and in the atmosphere. They must be shaded from direct sunlight, and when in full growth occasionally watered with weak liquid manure, that made from cow manure and soot being the most efficacious and safest. Frequent spongings are necessary to eradicate the small scale that attacks the foliage, and which if left alone soon spoils the appearance of the plants. *C. Lowianum* was introduced from Burmah in 1878 and has several varieties, these differing from the type chiefly in size and the colouring upon the lip.—H. R.

**Cattleya labiata** (white variety).—I am in receipt of a bloom of another albino of this lovely and useful Cattleya from W. Eastwood, of Newchurch, Manchester, who says that it has "just flowered for the first time from a dozen imported plants recently purchased." This bloom has the appearance of having been produced from a weak growth, and will no doubt be much finer another season. The sepals and petals are pure white, as is also the lip, which latter is distinctly veined with delicate rosy carmine. It resembles the beautiful variety *C. l. R. J.* Measures recently noted in THE GARDEN, although not of such fine form. This possibly may be owing to the weak state of the plant. W. Eastwood may congratulate himself in having such a fine form occur out of a dozen plants. If it blooms next season I shall be pleased to see a good fresh flower.—W. H. G.

#### HYBRID CYPRIPEDIUMS.

For several years past there has been a marked increase in the numbers of hybrids shown by various raisers from time to time. If anyone should have entertained the idea of any cessation in the supply he will find it far otherwise; at least this will be the case as far as Messrs. Sander and Co. are concerned. The hybrid Cypripediums alone are a most important feature in this establishment; there are literally thousands of them at the present time in various stages of development, from the larger ones showing flower down to the very tiniest speck, scarcely discernible upon the surface of the soil. In the raising of these hybrids order and method are strictly followed out, and every past experience is brought to bear upon the hybridisation now carried on. When it is known what results have been obtained by intercrossing various species, many of which are far removed from each other, the process of raising seedlings from these same and other crosses becomes all the more interesting. The practice at St. Albans of sowing the seeds in the pots of other Orchids may be the same as practised by other raisers, but it is here followed out in a most systematic manner. These are raised not only in the pots of other Cypripediums, but also in those of *Lælia* and *Cattleyas*, nearly all of these foster-parents being themselves hybrids. The healthy growth of these seedlings is most remarkable; they are thriving like so many annuals of the easiest possible culture. Of hybrids in flower early in January there were *C. Calypso* (Oakwood var.), a very distinct and choice hybrid, in which the colour is intensified. Another hybrid, the result of crossing *C. Curtisi* and *C. Rothschildianum*, bids fair to be a decided acquisition; two such parents should result in a fine offspring. *C.*

*graude*, another hybrid, was very vigorous. Beside it was *C. nitidissimum*, one of the very finest and choicest hybrids of the *Selenipedium* group. *C. Leeaunum giganteum* was in its best form. Another variety named *virginale* was most decidedly distinct in its pure dorsal sepal. *C. nitens* (Sander's var.) has flowers of great substance and with darker spots than the type. *C. Lathamianum aureum* is a richly-marked hybrid suffused with a golden shade; *C. Masereelianum*, at one time exceedingly choice and still far from plentiful, is also fine. *C. Lynchianum*, the result of crossing *C. Spicerianum* with *C. selligerum majus*, is a most promising hybrid. *C. Leeaunum James Hamilton* is a very attractive and fine form, distinct from, but quite equal to *C. l. giganteum*. ORCHIDS.

#### SHORT NOTES.—ORCHIDS.

**Lycaste Skinneri Reginae**.—This, which I recently noticed flowering in Mr. Williams' nurseries, Upper Holloway, is a very distinct and striking form, of large size and good substance, the broad sepals being white, slightly flushed with rose, the petals shaded with a rich shade of carmine.—W.

**Lælia anceps Fitchiana**.—I recently saw a very distinct form of *L. anceps* under this name. The flower is of very large size; the side lobes of the lip, well reflexed and prominent, are mottled with a purplish-mauve colour, as are the other segments of the flower. It makes a pretty contrast to the darker as well as the white varieties.—W. G.

**Cœlogyne cristata** (Chatsworth variety).—Some very large specimens of this choice variety are now a mass of bloom at Harrow Weald House, many of the pseudo-bulbs measuring 6 inches and more in circumference. This is one of the most useful and easily grown Orchids we have, but to grow it to perfection it certainly requires some extra attention. *C. cristata Lemoniana*, with the citron-blotched lip, was also in bloom, and very distinct from other kinds.—W. H. G.

**Cypripedium Dauthieri striatum**.—Under this name comes a bloom of this hybrid from "G. M.," but it is far from being an improvement on the typical hybrid. *C. Dauthieri* is a cross between *C. barbatum* and *C. villosum*, and when represented by a good form is a very desirable kind. The variety here referred to is perhaps better known as *C. Dauthieri marmoratum*. The mottling on the whole bloom is very irregular and not at all pretty. This form is by no means uncommon, as it has appeared in many collections.

#### FLOWER GARDEN.

##### SELECTING THE FINER MICHAELMAS DAISIES.

To make a selection of the choicer Michaelmas Daisies much depends on a person's experience with them, because some of the most meritorious varieties under some conditions do not display their best features. Most of the trade lists that have reached me since autumn, 1894, have not, so far as I can see, adopted the modern names as authorised by the Aster Conference a year or two ago. I think this is a mistake or an oversight, for though much may be said in favour of sticking to old names in many cases, this is not one of such cases, but extremely exceptional. The Aster muddle called loudly for the revision, kindly made and well done by the Aster Conference, and their revised nomenclature—whether perfect or imperfect—has at least the claim of being the only one capable of being intelligibly followed. And further, owing to the fact that most of the choicest Asters are garden hybrids, it was not so much a botanic as a florist's set of names that was needed. But still worse, not only under the "old style" were, and still are, the names and plants mixed, but many nurseries have their own style—that

is, there is no sort of harmony in trade lists or trade material. This makes confusion more confounded, and it encourages that form of laxness which is, perhaps, the worst of all, for when a genus of plants is in a state of confusion, it largely takes away the personal responsibility of those who distribute the plants.

But to take things as they are, the best must be made of them, and as it is desired to get the best kinds in quantity, and as trade lists are the only sources, generally speaking, I fear that to some extent more must be secured for trial than are ultimately intended. The descriptions of the Aster committee, as furnished in the R. H. S. "Journal," vol. xv., parts 2 and 3, January, 1893, will be indispensable, and perhaps on the whole will afford the readiest means of getting together the best varieties; they at least point out many of the best kinds from a florist's point of view.

My own plan has been for years, with the object of finding the best Asters within the limited number of forty to fifty, to watch every likely trade list, and no matter what the names are, if they give the least hint of being something different from well-known varieties or from those either being grown or such as have already been tested, to secure a specimen. I have found many good Asters in this way, but I fear that it would be discouraging did I mention the scores of rubbishy kinds that had no value for a garden. In getting plants in this way the name with which they come is of little or no moment. If the flowers are not good they go, if worthy they stay, and the correct or approximately correct name is then sought for. Many good varieties have been discarded that would be well worth growing in a smaller collection than fifty, on the principle that they would not in a smaller collection have other varieties almost similar, or rather need not have in a small collection, and even in a larger collection than fifty they might be retained, simply on the score of variety and quality. But that is where I think the advantage of a limited number comes in. If, say, you limit your selection to forty, you can afford to discard good varieties when they happen to be very near to a preferred variety, and the result will be quality with wider distinctions. By no means an important point to watch in selecting the autumn Asters is the respective periods at which the kinds are at their best, so as to secure a long and even succession of bloom, or even when desirable to have the chief bloom within a given month. To accomplish this, whether the desirable period were early or late, I fear some of the best varieties would be shut out. As, for instance, did you insist on late September or October flowers, most of the beautiful vars. of the *Amellus* group would have no place, and did you want a September bloom merely, the *Novæ-Augliæ* group, all the four or five of which are superb, would be of no use.

And after all, you learn most and best by experimenting. Besides, you will learn in your own garden, what no one can tell you, as to its capabilities with these plants. The land may suit certain kinds to perfection, and with such kinds you will excel. Others may do as indifferently, so amenable are these plants to various soils and climate. But in every case it will be advisable to grow the plants for at least two years to do them justice, as in many cases, especially the cordifolius group, the kinds are more notable for their habit than their individual heads of flowers. March will be a suitable time to plant, and I would plant by preference in a stiffish loam, deeply dressed and manured. J. Wood.

Woodville, Kirkstall.

## THE GREAT ALPINE ROCKFOIL.

(SAXIFRAGA PYRAMIDALIS.)

As shown in the accompanying woodcut, this plant is one of the most useful and beautiful that could well be grown, and all who possess a garden, however small it may be, can have this floral pyramid in the greatest perfection without the assistance of artificial heat of any kind. In Dr. Engler's monograph of Saxifragas this plant is put as a synonym of *S. Cotyledon*. Although long considered in gardens as a distinct variety of that species, I am still of the opinion after having seen them growing together for the past ten years that the two are quite different. I have had wild plants of *S. Cotyledon* from Norway and the Pyrenees, and they are quite different from this gigantic *S. pyramidalis*. The latter throws up large spikes 2 feet to 3 feet in height, thickly covered with white, rose spotted flowers, forming a most charming pyramid, very useful in the decoration of the greenhouse and the conservatory. It is biennial so far as that the rosettes producing the flowers die when the season is over, but previously from the base of these old crowns are produced from six to a dozen or more of young ones ready to take their place the next year. When the plant is used for indoor decoration these young crowns are taken off and potted in good rich compost, grown on in a cool north house or frame and shifted as required until finally they reach the pots in which they are intended to flower. When the plants become pot-bound, a weak solution of liquid manure will be found beneficial. On the rockery the plants require to be planted annually, and new soil should be given them when this takes place; 6 inches apart will be sufficient, and if healthy and vigorous the plants will very soon almost meet each other. They make a pretty group in the open, and are much appreciated by those who have only seen the wild species on the Alps. K.

## COLOUR IN FLORISTS' FLOWERS.

TWENTY-FIVE years ago or more, when I first became acquainted with cultivators of florists' flowers, they had, as many have now, fixed ideas of colour as well as form in these flowers. The colours must be "bright, deep and rich." I well remember a striking instance of this on an occasion when the southern section of the National Carnation Society held an exhibition in Mr. Charles Turner's nursery at Slough late enough in the season for nearly all the leading northern growers to be present. Several very beautiful new seedlings were exhibited, and amongst them a handsome rose-flaked Carnation with large well-formed flowers; it was of a soft pale rose colour, which harmonised beautifully with the pure white. I pointed it out to the late Mr. Arthur Potts, but one glance was enough. He "would not have such a flower in his collection." It was passed over by all the northern judges; they would have rich deep rose colours and no other. I also produced from seed what I thought was a very pretty bizarre Carnation; it had stripes and flakes of rose and purple on a white ground, and when I put it in the bizarre classes I was told by one of light and leading amongst the northern florists to put it amongst the fancies, or I would be disqualified. No one cared for it, so I grew it for my own pleasure, until the editor of THE GARDEN offered prizes for the best Carnations in the various classes, and I sent the despised and rejected Carnation to be tried again. It won the first prize in the class, and was named Harmony because of the beautiful blending of the colours. It has gradu-

ally crept into cultivation, and is exhibited in the stands of show Carnations, but the strict florist will have none of it.

And so variety in colour is sacrificed to a preconceived notion that the colours in Carnations, whatever they are, should be of a dark, and not of a pale tint. The Auricula is even a more notable instance of this dogmatism. Like the Carnation, it has been a favourite garden flower for at least 300 years, and the point of excellence, the only standard worth working for in the eyes of the old-fashioned florist, is black. He calls it black, and when contrasted with the pure white centre of the flower it is as near black as possible; and when a variety with a splendid truss and perfectly formed flowers was produced with a plum or violet colour it

Harrison Weir esteems them highly for their sweetness and beauty.

I have been tempted to write on this subject because in any standard of excellence set up by florists a free play should be given to Nature in regard to colour, or a blending of two colours; the latter is also of some importance. When quite a young beginner I remember admiring a very beautiful seedling Polyanthus, but the stern old judge, long gone to his rest, at once rejected it because the yellow colour of the margin was not of the same tint as the centre. If I mention the Tulip, it will be with some diffidence. I admire it in all its beautiful tints of flame and feather, nor can we ever cease to remember all that the florists have done, not only in producing, but in preserving to us for so many years this and all the other beautiful garden flowers. We know and appreciate what they have done; we can only guess at what they might have done had not their minds been narrowed down to a certain groove as regards colour, to say nothing of form which might very well occupy an entire paper to itself. I mention the Tulip in this connection because the disqualifying points seem even more inexplicable than they do in that of the Auricula or the Carnation. A flower may be very beautiful in its form of petal, the purity of its cup, and the delicate tracery of flame or feather, but the anthers may be stained, and it is put aside at the exhibition. The anthers may be right in the next flower examined; it may have a rich dark-pencilled feather, but the beam, as it is termed, is of a light colour, or it may have a rich red and dark crimson on a deep yellow ground, and because of these two colours it is again rejected. "It is a tricolor, it is of no use," exclaims the florist. On this point of colour I know I am at variance with some of our best florists. If the exact colour flowers ought to be is to be defined with the exact form, &c., it seems to be very much like judging them by square and rule.

The great Alpine Rockfoil (*Saxifraga pyramidalis*). Engraved for THE GARDEN from a photograph sent by Mr. Hodder, Ponsoby, Torquay.

was cast out, and the rubbish heap became the receptacle of what might have been a thing of beauty, to be admired in the gardens of all tasteful persons. The same censorious spirit prevailed amongst the Polyanthuses at one time; all were rejected for black or dark maroon ground colours. Now they have ventured to classify them and distinguish between dark and red ground colours. Ever since I cultivated florists' flowers I have withstood this stifling of Nature in our favourite garden flowers, and it is some satisfaction to be supported by persons of undoubted artistic taste. In regard to the Carnation Harmony, the eminent flower artist, Mr. Moon, told me it was the most beautiful of its kind as regards harmony of colour; and in respect of the fancy Auriculas which the florists throw away, Mr.

The preference of one colour before another, or insisting on one colour only where there might be two equally effective, seems to some a dogmatic attempt to define beauty as something to be measured or meted out to cultivators of flowers. Our ideas of what is beauty in the flower garden have been changed in modern times. We may now go more into detail, and ask ourselves, what is beauty in a florist's flower? Surely not a long array all of one colour and all of one form. Variety is charming, and it is well that we have as much variety as possible in our gardens in colour as well as in form. A florist would throw away any Carnation in which the edges of the petals were fringed, and when the flower is a bizarre, a flake or Picotee, I believe the florists are right, but when we have the fringed edge in a border Carnation and the variety is self-coloured, I would say save it, grow it, and admire it. J. DOUGLAS.

**Edelweiss** (*Leontopodium alpinum*). — The most successful way of treating this plant under cultivation is by regarding it more in the light of a biennial, though, perhaps strictly, it may elaim to be a true perennial. Be this as it may, I have

never been so successful when growing it from division as when the plants are raised from seeds. Thus treated and by sowing a few seeds each year so as to make sure of some flowering tufts annually, it possesses greater vigour and produces its singular woolly heads more freely. It is surprising how varied is its growth in different soils and localities, and in no garden or locality have I seen it at any time so luxuriant as at Pusey House, in Berkshire. In these gardens it was a perfect picture. Seeds ripened freely, and by making sowings early in the year strong plants were ready for planting out during the summer. When planted out they always made rapid progress. At the time of flowering the plants were fully 1 foot high and were much admired.—E. J.

#### SOLDANELLAS.

THESE constitute a small group of extremely pretty and interesting alpine plants that are rarely seen in good condition in our gardens: indeed, their culture, so far as concerns maintaining them permanently in health and vigour, seems only indifferently understood. For a season or two the imported plants grow and flourish in the most encouraging manner, and ultimately attaining, as it were, their greatest perfection, send forth their tiny flower-spikes and pleasing flowers from almost every crown. But after this the plants appear to lose much of their vigour, and though a similar course of treatment is kept up, only a scanty growth and flowering are the result. In various ways, by pot culture and planting out in moist, shady spots in sandy peat and leaf soil, I have endeavoured to get a return of their former vigour, but without success. The general appearance of the plants is that of exhausted energy, which is not resuscitated, as is the case with many plants, by division and fresh soil. Whether the plants may in a measure be revived by dividing them into very small scraps and pricking them out after the manner of seedlings I do not know, as I have not tried such small divisions. Perhaps the better way of attaining success would be by obtaining fresh seed as far as possible, at the same time using every means of seeding the plants we have. In this way it may be possible to get greater vigour into the plants than when increased by division; at any rate it is worth a trial. Seeds of these plants, or at least some of them, would, I doubt not, be obtainable either from specialists at home or abroad, and if these were successful, a year or two would be sufficient to grow them into good plants. Some well-filled pans of these dainty spring alpine plants would come as a pleasant surprise to many lovers of alpine plants, and others who may not have seen them previously could not fail to be interested also. When gathered together in a sheltered nook in loam, peat, and leaf soil in about equal parts, the few species of which this genus is composed are very interesting. It is better, perhaps, to grow them thus, because they are then more readily accommodated with one essential in their culture, namely, moisture. In view of this I have wondered if any grower of alpine plants in the British Isles has attempted their culture in Sphagnum Moss, and with what result. When we hear of the success attending this method of culture in other parts of the world, and with some of the most unmanageable of rare alpine plants, the question of soils dwindles into insignificance. And it is quite possible that the moisture-loving nature of these Soldanelles may yield to this kind of treatment and produce better results than when grown in soil in the usual way. At any rate, with such a charming little group it is at least worth a trial when other methods only partially succeed.

*S. ALPINA* is the best known, perhaps, having been introduced upwards of two centuries ago. In height this species rarely attains to more than 4 inches or 5 inches, forming close upon the ground tufts of shining and somewhat kidney-shaped, leathery leaves. From these in March or April appear the tiny flower-stems, bearing pretty bell-shaped blossoms of a pale blue shade. The flowers, of which there are several on a stem, are deeply cut into narrow segments, having the appearance of a heavy fringe. Not far removed from this is

*S. MONTANA*, except that it is larger in all its parts, and consequently more vigorous. The flowers are also of a deeper shade of purple-blue and the corolla more deeply cut. I have been more successful with this kind than any, and, owing to its more vigorous nature, perhaps, the plants have attained fully 6 inches or 7 inches high, and borne from four to five flowers in a scape.

*S. PUSILLA* has blue flowers, the margins of which are not so heavily fringed and the scape usually only one-flowered.

*S. MINIMA* is a very tiny plant, as the name implies, rarely growing more than 3 inches high. This has flowers suffused with lilac, usually but one in a scape and prettily fringed at the margin.

E. J.

#### THE ROCK GARDEN.

##### WINTER EFFECTS.

JANUARY is, no doubt, the dullest and dreariest month for the rock garden, and plants which bloom at this time of the year are welcome. During the second week of this month we had here in the western counties (Devonshire and Cornwall) frost varying from 10° to 16°, followed by deep snow. But at the time of writing (third week in January) the signs of winter have already passed away, and on looking over various rock gardens, one cannot help being struck with such plants as present a pleasing appearance or are even in bloom at this season. In a well-arranged rock garden, plants of this class should be distributed with the greatest care, and should form a special feature in those portions which contain deciduous or late-flowering plants, and would, therefore, without such help look dull and uninteresting for several months to come. Christmas Roses have already been in bloom for some time, and form a most suitable material for intermixing and forming irregular groups among the larger kinds of late-flowering plants, especially in the rougher parts of the rock garden reserved for plants of the more robust class. This system of planting has great advantages, for later in the season when the Hellebores are past their foliage would set off the flowers of other plants succeeding them.

Among the earliest plants of the robust class I may mention *Iberis sempervirens* and *Geum aurum*, which here at Exeter are already in bloom in an exposed position out-of-doors. *Geum aurum*, by the way, is not so well known as it deserves to be. Its large handsome flowers are of a deep rich golden yellow, while the evergreen leaves are large and glossy, constituting quite an ornament in themselves when the plant is not in bloom. The flowering of this plant at this early season is no doubt premature, but it is none the less valuable on that account. There is no difficulty whatever in growing this *Geum*, as it seems at home in any soil or situation. Cyclamens are also now in bloom, and are ornamental both in their flowers and foliage. For plants now in bloom in a half-shady position few can surpass the blue *Hepatica angulosa* and the charming *Anemone blanda*. The deep azure-blue flowers of this *Anemone* rival those of the *Gentian* in brilliancy, and therefore make it most desirable, especially as its cultivation is so simple.

One of the neatest rock plants for winter flowering is *Iberis stylosa*. Here it has been in bloom for some time, and is now (third week in January) thickly laden with its pretty mauve blossoms borne well above the dark green glossy foliage. This plant is of exceptionally neat and compact habit, and is fit for the choicest rock garden. It does not spread rapidly like its congeners of the *Iberis sempervirens* type. The plant in question is growing here at Exeter in rather stiff loam, mixed with stones, on a sunny slope, which seems to suit it. On the same slope a square yard or two is covered by the pretty little *Ionopsidium acaule*, with its neat lilac-coloured blossoms fully expanded. This plant grows freely from seed sprinkled on the open ground, and forms a quickly spreading, but very neat carpet. It was sown on the sloping ground last spring and has flowered continuously throughout last summer and autumn, the flowers being scarcely more than 2 inches above the ground. The parent plants are now dead, but from their self-sown seeds has sprung a colony of plants which are now in full bloom, although less than a fortnight ago we had 10° of frost followed by snow.

Returning to perennial rock plants, I may mention the well-known *Gentiana acaulis* as a most valuable plant for winter effect in the rock garden. Not only is the foliage crowded together so densely as to form a bright green carpet, but it often happens that its large deep blue flowers appear as early as January. It is so this year, and I have already seen several blooms fully expanded, though the proper time for flowering is not till March or April. *Gentiana verna* (generally the first of the *Gentians* to bloom) is not quite so far advanced this season, and it will probably be some weeks before its buds are open. Its foliage, too, is not so conspicuous as that of the larger *Gentiana acaulis*: and although *Gentiana verna* is one of the choicest gems for our rock gardens, the other variety (*G. acaulis*) is certainly the most effective during winter. Other choice rock plants just now coming into bloom are *Saxifraga Burseriana*, *S. sancta* and *S. luteo-viridis*, all of which do best in a sunny position on sloping ground. *S. luteo-viridis* (often erroneously called *S. Frederici Augusti* or *S. purpureo-lutea*) is here the most advanced of these varieties, and at the time of writing the pale yellow blooms are already expanded, and stand out most effectively from a dense cushion of bright green foliage. *S. sancta* and *S. Burseriana* are just unfolding their blossoms, and in another day or two the rocky ledge from which they spring will be a picture pleasant to behold. I have so far confined my remarks to plants now in bloom, giving examples only of such as have come under my own observation. There are probably many other kinds elsewhere already in full bloom, but I think even the few I have mentioned will suffice to show that our rock gardens need be by no means so bare of flowers in the winter months as they generally are.

It is, however, not with flowers only that we may embellish our rocks during the dull season, but we may also choose from a very large number of plants whose foliage looks fresher and brighter in January than during the summer months when flowers are plentiful everywhere. The foliage of many evergreen plants changes colour during winter, and striking effects may be produced by tasteful combinations. How very effective, for instance, is *Galax aphylla* growing from a carpet of *Arenaria balearica*. The latter clings close to ground or stones, clothing them with the brightest green, while *Galax aphylla* grows about 6 inches high and its

ORCHARD AND FRUIT GARDEN.

GRAPE MRS. PEARSON.

THIS magnificent Grape does not appear to be planted so extensively as its merits would seem to warrant, yet all who have grown it speak in the highest terms of its general excellence. In my opinion it is only second to Muscat of Alexandria amongst white Grapes, and on some soils and situations it is really superior to that famous variety. Many Grape growers find Muscat of Alexandria shrivel at the ripening period or immediately afterwards in spite of all their efforts to prevent this, but Mrs. Pearson planted in the same house and by the side of the variety named not only produces a heavier crop, but is free from shrivelling in the berries,

from Vines planted in almost all sorts of soils. I have had charge of it grown in black, light, and heavy composts, in all of which it succeeded admirably, while some other varieties were pretty much a failure in the same vinery.

To get extra fine bunches of model shape I find it best to prune to the second or third bud on the lateral, whichever may be the most prominent. Such buds never fail to make a large bunch, but there is a risk that too many of these big bunches may be left on. Provided the Vine is in vigorous health, it is marvellous how the bunches will increase in length and breadth, considerably exceeding the estimated size, and the grower is loth to remove some of these fine bunches when it is observed that the crop is too heavy. Under those conditions it is a good plan to remove a bunch or two, thereby relieving the Vine of the strain somewhat, and also ensuring large berries with a high finish.

Another item is to endeavour to get each berry with its full number of stones; if four can be secured in every berry, they will attain a larger size than if only two stones were in them. To secure this result a perfect set is indispensable, requiring extra care at the flowering period. Naturally Mrs. Pearson is a free setter, but it may be assisted in a great degree by maintaining a warm buoyant atmosphere, with a night temperature of not less than 65°, rising 10° in the day. In the middle of the day a sharp rap with the hand will distribute the pollen, causing it to fly in all directions, and this rapping of the rods should be continued daily until all and every part of the bunches are set.

Another great aid to a free set and also the forming of the stones is an application of 2 oz. of superphosphate to every square yard of the border given at the time of starting the Vines, a similar dose being given immediately after the fruit is set. White Grapes appear to be more benefited by this dressing than black do, and Mrs. Pearson especially seems to enjoy it. From careful observation I feel sure that lime ought to be more employed in many gardens for Vines, and the lack of that essential element is a frequent cause of bad setting and indifferent health. There are various modes in which lime can be applied

with advantage. Superphosphate seems to have the best effect on light and medium soils, while those of a heavier character are most benefited by bone meal and basic slag. The latter should be applied early in the season at the rate of 2 oz. or 3 oz. to the yard, and as it is slow in action no immediate benefit will be apparent. These manures will supply the lime necessary for the Vines and their crops without setting free the other constituents in the soil, and may be given with benefit in addition to natural manure in a liquid or solid form. W. G. C.

**Plum Oullin's Golden Gage.**—I do not know of any better all-round variety than this, as it does well in most localities. This is an early Plum, well worth room in all gardens, and is little inferior to the best of the Gages. I have it only

Grape Mrs. Pearson.

and will keep perfectly sound and plump until May, which is usually as long as Grapes are required to keep. Under good management and provided the Vine is not overcropped, the flavour of Mrs. Pearson is infinitely superior to that of many Muscats, and when exhibited in perfect condition Muscats must be good to beat it in an open class for white Grapes. On several occasions in judging white Grapes I have voted in favour of this variety taking premier place, feeling well satisfied that it deserved that position. My contention always is that a badly-ripened, green or rusty stand of Muscats bears no proper comparison with well-finished Mrs. Pearson or other perfect white Grapes. One very important advantage Mrs. Pearson possesses, viz., not being at all particular as to soil, splendid bunches and fine, beautifully coloured berries being obtained

leaves are of the brightest scarlet just now, forming a most delightful contrast to the vivid verdure from which they spring. Very valuable, too, at this season are the many evergreen plants bearing brightly coloured berries, such as *Gaultheria procumbens*, *Vaccinium Vitis Idæa minus*, and other dwarf rock plants. But even without such contrasts of colour many of our best rock plants are in themselves highly ornamental. Very few plants can be more effective than that lovely queen of Saxifrages, *S. longifolia*. Who has not observed that the silvery rosettes of this beautiful Pyrenean Rockfoil are much whiter in winter than in summer? This is on account of the silvery encrustations of the leaves having attained their full maturity. A group of this Saxifrage planted almost horizontally into the upright or slanting fissures of a dull reddish-coloured rock looks as though it were coated with a permanent covering of hoarfrost, and forms a most pleasing picture.

Among other rock plants with silvery foliage I will only mention *Antennaria tomentosa*, which, though not as white as in summer, is nevertheless of a pleasing silvery grey, and the same might be said of *Alyssum serpyllifolium* and *Alyssum spinosum*, which, though not in bloom, are a great ornament to the rock garden on account of their compact silvery foliage. Of the many varieties of *Sedum* none are prettier and more effective at this time of the year than the kinds with either bright green or red foliage. Perhaps the brightest green of all is that of *Sedum crassifolium*, whose fleshy and glossy leaves impart an unusual brilliancy to that plant. This variety does not appear to be very generally known, but it cannot be too highly recommended. It grows about 4 inches high and bears yellow flowers in summer. It should be planted in masses, perhaps between taller plants that would flower at a different season. All through the winter the bright green of its glossy foliage is very striking. Of red-leaved *Sedums* (*i.e.*, red at this time of the year) I will mention *Sedum rupestre* and *S. pruniatum*, both of which form an excellent carpet of bronzy red.

In conclusion, I would call attention to the vivid green of such plants as *Hutchinsia alpina*, *Draba ggas* and many of the mossy section of Saxifrages, which might with advantage be employed for the double purpose of making the rock garden look more cheerful during winter by their verdure and at the same time form a most useful means of carpeting the ground between taller plants that would flower at a later season.

F. W. MEYER.

Everet.

(To be continued.)

**Aster cabulicus.**—I am most grateful to those correspondents who have given information respecting this species. Be *A. cassubius* a well-authenticated name or otherwise, it will be seen the plant meant is but a variety of *Amellus*; whereas *cabulicus* is a species so distinct as to belong more correctly to another genus, and is called *Microglossa albescens*.—J. W.

**Megasea Stracheyi.**—This, as a hardy plant, and as is often the case with fame, does not prove of much use with me. True, the flowers are a delicately tinted white, and of good size and bold spike in strong plants, but there are always drawbacks with such delicate flowers produced near the surface out-of-doors, and one can seldom see the flowers perfect. Nothing can be more unrepresentable than white flowers in a soiled state. The coloured *Megaseas* do not spoil, and they have taller scapes and brighter foliage. This is worthy of note—about the foliage—because the *Megaseas* have much of their value in the almost evergreen quality as open-air plants.—J. Wood, *Woodville, Kirkstall*.

in bush and cordon form, but last season in Kent I saw some very fine standard trees loaded with fruit. Its season is about the middle of August. It does grandly on a west aspect as a wall tree. With me, on a light poor Plum soil this variety succeeds where others fail, and the trees crop freely. I saw fine crops in Scotland a few years ago, thus proving its hardy free-growing character.—W. S.

**Grapes for a private garden.**—However interesting it may be to grow a collection of varieties of Grapes, it is pretty well known that the greater part can be very well dispensed with when it comes to the question of making a selection suitable for supplying a gentleman's table with high quality fruit. For this purpose Mr. Douglas (p. 1) limits his selection to seven varieties, and substitutes Black Alicante for Royal Vineyard. These, as it happens, are actually the varieties I grow here. Black Alicante is a fine showy Grape and succeeds admirably with me, but after the Mrs. Pince are finished I generally have a reminder that the quality is going off when the Alicante are being sent in. If Appley Towers black Grape as I saw it with Mr. Hudson at Gunnersbury House last autumn keeps up its good character, it will either form a good substitute for Black Alicante or a good companion. Previous to limiting the number of varieties to those above stated I used to grow Gros Maroc, Alnwick Seedling and Gros Colman, but as the quality was not cared for I had to cut them out. It is quite evident that as a rule there is too much of a mixed medley of varieties grown. When well grown Gros Colman suits some people, but as a rule it is seen anything but well coloured. A friend of mine who is very partial to experimenting with Grapes, especially in trying varieties on different stocks, showed me last November some splendid bunches of Gros Colman, the result of grafting on Madresfield Court. This latter is such a fine quality Grape that very few people would think or care of putting an inferior variety on to it. The berries were the largest for the variety I have ever seen and beautifully coloured. In the same house there are several Vines of the same variety on its own roots, but the fruit was not to be compared with that of the grafted Vine. Muscat Hamburg, again, we know is a splendid Grape, but it requires careful culture.—A. YOUNG.

#### SMALL PEARS OF RICH FLAVOUR.

THE rage for size is causing many of our small varieties to be greatly neglected by planters, but, although small, many of these Pears are of most delicious flavour, and the majority of the sorts are regular bearers, and far more certain croppers than the larger and more imposing sorts. In some gardens the smaller Pears are most appreciated on the dessert table, being of a more useful size than the big ones, and frequently of a superior flavour. The following varieties in their order of ripening are all small or comparatively so, and will afford a succession of well-flavoured fruit from July to well on into the spring months:—

**DOYENNE D'ETE** is well known for its earliness and pleasant flavour if eaten as soon as gathered from the tree, which crops profusely in all forms. Cordons especially bear heavy crops, and it must be a bad season indeed if this variety fails.

**MILLE SOULANCE** runs the preceding variety closely in earliness and good qualities, both ripening with me in July. Since planting this sort five years ago it has borne freely every year.

**CITRON DES CARMES** is another small early variety, the most highly-flavoured fruit being obtained from bush or standard trees. From such trees ripe fruit is produced from the beginning to middle of August. On walls the Pears are not so juicy, and according to my experience the trees in such positions are very prone to Pear scale.

**DR. HOGG** is a small, handsome Pear that should be better known. The fruits are beautifully

marked with red on the sunny side, and produced very freely both on the Quince and Pear stocks, and also on all forms of trees. In addition to those good qualities, the fruit is of a most pleasing flavour, and liked by all Pear lovers; in use during September, early or later in that month, according to situation of the trees.

**EYEWOOD** is a small October Pear, of excellent quality on our light soil, succeeding admirably in bush form, and is a continuous cropper, rarely failing to be more or less productive.

**ASTON TOWN** is an old favourite; the fruit, though small, is of delicious flavour. I think no variety bears such enormous crops on standard trees as this on almost all sorts of soil and in cold or warm localities. I have a strong recollection of having to assist to pick many bushels from great trees when under a well-known northern gardener, and also remember his advice, viz., "If ever you have to plant standard orchards, put Aston Town on the most exposed side to break the gales." The behaviour of the variety at that place proved the thorough soundness of the advice, as the trees had attained a large size and were very prolific.

**COMTE DE LAMY** comes into use about the same time as the last-named (October and November), and on good soil is one of the best Pears grown. By thinning out the fruit it may be had of fair size, but, as a rule, the trees are too prolific to produce big fruit.

**WINTER NELIS** is a well-known and favourite Pear, especially noted for its rich flavour, good keeping and productiveness. Seasons influence its period for use, but, as a rule, it may be relied upon from the end of November to end of January. For use after Christmas I believe

**JOSEPHINE DE MALINES** has no equal; the quality of the fruit is Al, and is in use from January to March inclusive. In every part of the country that I have known this excellent variety it has cropped well on walls, and in warm and suitable districts bush trees are heavy bearers. To have the fruit as long as possible it should be allowed to remain on the trees to the latest possible date, only gathering it on signs of sharp frosts; in fact, I have had the fruit out in several degrees of frost without its suffering any apparent damage in either flavour or keeping afterwards.

**MARIE GUISSÉ** is a most delicious Pear, in use during February and March, but, unfortunately, it is not a success with me except on cordon trees. Bush trees in the open having been a complete failure for a number of years, they have been rooted out. In some other places I have seen this bear splendid crops, and where it is a success it should have a place in even small collections, being so valuable for its lateness and high quality.

**VAN DE WEYER BATES** is a variety that I made a note of last year as being a grand late Pear; fruit that I tasted in April was very rich and juicy, and the grower stated that the trees cropped profusely on the Quince in all forms. Not having grown this sort I cannot speak of its hardness or otherwise, but I have no doubt it would answer in cold districts against a wall.

W. G. C.

#### Gros Maroc and Black Hamburg Grapes.

—A reader of THE GARDEN writes me that Black Hamburg Grapes realise such a low price that he has decided to graft his Vines with Gros Maroc, and asks if it will not prove more remunerative. Many Grape growers have been disappointed at the low price of such fruit of late years, but in spite of low prices good bunches of Black Hamburgs, well finished, will sell at paying figures. I think most fruit growers will admit that this famous and highly popular Grape is not so well grown generally as it used to be, and purchasers will sooner pay more for highly-coloured Gros Maroc than for Red Hamburgs. The latter variety has advantages over its rival in becoming profitable earlier, and under good management producing a heavier crop. Gros Maroc is somewhat slow in getting established, afterwards acquiring almost too gross a habit; and although

started at the same time as Hamburgs in an early viney it is at least a fortnight later in ripening. There is also the question to be considered of how long the purchasing public will prefer showy Grapes at the expense of quality. According to my experience in selling to fruiterers the tide is turning, and Grapes of rich flavour are more valuable than they were two or three years ago. It is possible, therefore, that those growers who discard such a good all-round Grape as Black Hamburg for an indifferently flavoured variety like Gros Maroc may find they have made a mistake. If the former were better grown, by giving it more air and not so highly fed, also giving careful attention to other cultural matters, it would still hold its own amongst Grapes for all purposes. Some years ago I manured Black Hamburg Vines as liberally as Alicante and other varieties, but although the bunches and berries were large, the colour was not what it ought to be. Later experiments proved conclusively that less feeding was better, as shown by the deeper colour and beautifully hammered berries.—W. G. C.

**Peach Dymond.**—This Peach is fully deserving of all the praise that the several correspondents of THE GARDEN recently have bestowed upon it, and although as yet I have not tried it for forcing, I shall do so at the earliest opportunity. I have several trees in late houses, and it certainly has been looked upon in its season as one of the very best. It develops a splendid colour, and being a very firm fruit travels well, and its quality is first-rate. It has one failing with me in its susceptibility to the attack of aphides during the summer season. Each year as soon as the leaves commence active growth after the flowering period is past the fly appears on this Peach when other trees would be quite free, and syringing with an insecticide must be resorted to early to prevent its spread to other adjoining trees. Whether this is common to the variety in other gardens I know not, but I do not find any reference to this failing by other growers who have recently brought it into prominence. It would be interesting to know whether it is a general or only a local failing. Each of the four trees I grow has the same tendency, and this makes me think there is some inherent weakness in the variety, or the soil is deficient in some element necessary for its healthy growth. I get good crops yearly of the character described notwithstanding the attack, which is, however, in evidence only in its early stages of leaf growth. It is a splendid variety for open walls.—W. S., *Rood Ashton.*

#### MEALY BUG ON VINES.

IN a recent issue of THE GARDEN I notice "W. I." advocating scraping Vine rods infested with mealy bug. This, according to my experience, is superfluous, and generally admitted to be injurious. When I took charge of my present situation on November 1, 1888, I found an old lean-to viney so badly infested and in such a dilapidated state that I almost despaired of cleansing it. I first had the rafters, trellis, glass, and walls washed with a strong solution of soft soap and petroleum, and seeing the Vines had been rather severely scraped on previous occasions, I had them well rubbed with the hand, but no scraping was done, except about the spurs. They were then well scrubbed with soft soap and warm water, and afterwards dressed with a mixture of soft soap, sulphur, soot, and clay, with a wine-glassful of petroleum to a pint of water. The whole was allowed to simmer on a slow fire for twenty minutes, and applied in the usual way. The border (an inside one) was next cleared of all loose soil and top-dressed. Of course, nothing more could be done till starting the Vines. When the question of syringing arose, I decided to try how the Vines would break without it, as I could not see the sense of applying such strong insecticides and washing them off in a few weeks. When the buds showed signs of breaking a little heat was turned on, the evaporating pans filled, and a fair amount of moisture maintained without

syringing. I was pleased to see the Vines break remarkably well. Notwithstanding all the cleansing, in due course a few insects made their appearance. These were immediately destroyed by touching them with a small brush dipped in petroleum. The second year the same process was strictly observed with improved results, as only a very few insects appeared, which were destroyed as before. The third year the same process was maintained, when only two insects were discovered all the season. Since then, I am pleased to say, there has not been a bug in the house, and every year I see an improvement in both Vines and fruit (except two rods) viz., Lady Downe's and Gros Colman, which still show the effects of hard scraping and will never give satisfaction. I have no hesitation in attributing my success as much (or more) to the non-syringing system and strict watchfulness during the summer as to all the cleansing and dressing put together, and that without scraping the rods. R. R.

Belfast.

#### CURIOUS GROWTH ON VINE.

I ENCLOSE a sketch of part of the stem of a Bowwood Muscat Vine. As you will observe, there are a number of swellings between the spurs such as I have never noticed on Vine stems before. The Vine had all its natural bark on when sketched, and measured  $3\frac{1}{2}$  inches in circumference over the largest of the swellings in the sketch and only 2½ inches between the swellings. The Vines were planted in September, 1892, and carried a few good bunches last season. Theinery adjoining the Muscat house is planted in the same kind of compost, but there is very little swelling noticeable on the Vines. I should be glad of any information on the subject.—C. R.

\*.\* It is doubtful if a correct solution can be arrived at without first having a section of the affected rods to examine. Judging from the sketch furnished, the inner bark has been injured in some way and behaves in much the same manner as I should expect to find in the case of a stem of an otherwise healthy tree that has been attacked by either canker or American blight. When the bark is thus damaged or ruptured it frequently calluses and heals over, a swelling or circular ridge gradually closing over the exposed wood, and if the irritating cause of the wound is removed, the bark eventually unites all round, though there may be some dead wood underneath. The ridge or swelling would remain. All this might have been going on under the outer or dead bark of the Vines without "C. R." observing it, but if this is really the solution, he can easily verify it by cutting through one of the swellings. The question naturally arises, how is it possible for the live inner bark to be damaged in any way all the while it is protected by a thick covering of dead bark? It is not often that any injury is sustained by well-protected inner bark, but if petroleum has been used for either cleaning the roof or for syringing or dressing the Vines, this is apt to collect together, and is of such a penetrating nature as to be quite capable of injuring the bark of Vines on which it drips. An over-strong dose of other insecticides powerful enough when properly diluted to destroy insect life, is also fully equal to damaging the Vine rods, especially seeing how comparatively soft and porous these are. I am quite of opinion the swellings arise from some external cause, and not owing to anything being wrong at the roots. Naturally these swellings must greatly interfere with the steady flow and return of the sap, and will do so to a considerable extent as long as the rods are retained. This difficulty can most probably be obviated by a change of rods, and which can be done gradually or without the loss of a part of a crop even. Lay in young canes from near the lower part of the old rods, and stop these when about half-way up the house. Next year all or many of the spurs may be cut away from the lower half of the old rods, and the new rod be allowed to occupy the space and crop freely, also, in addition, extending to the top of the house. If

the Vines are in a healthy condition below as well as above ground, the young rods at the end of the second season's growth will be strong enough to fill the house, and the old rods should, therefore, be sawn off close to where the young ones started while yet the foliage on all is in a green state. If cut away directly the bunches are cleared off there will be no bleeding, but if deferred till the winter, it will be found a very difficult matter to prevent a wholesale loss of sap. If the swellings occur on the young rods, then it may be found necessary to make a wholly fresh start.—W. I.

**Two good stewing Pears.**—Those who require Pears for cooking will find Verulam and Gilgil two of the very best, the latter for early winter supplies and Verulam for spring use. Gilgil is one of the best flavoured of all the stewing Pears. It is a large round fruit, in season from October to December, and the tree does well on the Pear stock. Verulam is better known, and is little inferior in quality to the one described above. It is valuable on account of its keeping properties, and when cooked it is of excellent flavour and of a deep rich colour. Being a very large fruit it should not be grown on standard trees in an exposed position.—G. WYTHES.

**Apple Northern Greening.**—Cooking Apples are none too plentiful late in the spring, and the above is one of the best for keeping. I have seen many varieties recommended for keeping, but, so far, I have found few equal this, the quality also being good. It is not at all fastidious as to soils, doing well in standard form; indeed, it is a valuable market fruit if not gathered too early and given cool storage. I never attempt to keep this variety in the fruit room, it being stored in any out-building free of damp or rain-proof. I have kept heaps of this fruit in this way, as the skin being hard, it does not bruise badly. Old trees bear freely and do not like much pruning. I merely thin out the weak growth or cross branches about once in three years. In storing the fruit it is well to grade it, as the smaller fruits are not so valuable for keeping.—G. W. S.

## FERNS.

### VARIEGATED FERNS FOR THE CONSERVATORY AND COLD FERNERY.

WHEREVER Ferns are grown for their intrinsic value and not merely for house or indoor decoration, we usually find them planted out or at least arranged in a more or less effective manner, and according to the taste of their owners, either kept by themselves or intermixed with fine-foliaged plants. During the summer months, besides the variegated Ferns requiring a warm temperature, which may then safely be grown with the cooler ones, coloured Dracaenas, Begonias of the "Rex" section, Crotons, Pandanus, and numerous other fine-foliaged plants may with advantage be used for that purpose, but, although they may exist, these plants cannot at this time of the year flourish in a temperature varying between 40° and 50°, which is that allowed the majority of Ferns in cultivation, and with excellent results, as testified by the well-known ferneries at Nash Court, Faversham; Woolton Wood, Liverpool; Messrs. Veitch's at Chelsea, and many others, which retain their fresh appearance all through the winter months, although kept at a low temperature. But the monotony above stated may, and indeed is easily relieved by a judicious selection of Ferns distinct from all others by their variegated character, and forming a most pleasing contrast with the numerous sorts with foliage of various tints of green.

Variation is a characteristic almost exclusively peculiar to Ferns of exotic origin. Although in a list of British Ferns grown by Mr. P. Neill Fraser, of Edinburgh, and published by him in 1865, we find variegated forms of *Asplenium Adiantum-digrum* and *fontanum*, as well as variegated forms of *Athyrium*, *Blechnum*, *Lastrea Filix-mas*, *Polypodium vulgare*, *Polystichum angulare*, *Pteris aquilina*, and *Scelopendrium vulgare*, it is very doubtful whether in these cases the variegation was anything particularly striking, or whether it was sufficiently constant and showy to increase the decorative value of the plants affected by it when under cultivation. As these plants are now very scarce, if existing at all in any of our collections, we are justified in coming to the conclusion that, had their variegation proved permanent and ornamental, these plants, which owing to their hardness could be grown without trouble, and especially without the expense of glass structures and heating apparatus, would not have been allowed to drop into oblivion, and we conclude that either their variegation was insufficiently distinct to add to their beauty, or that they did not reproduce themselves freely either from spores or from division. Fortunately, such is not the case with Ferns of exotic origin, all or nearly all of which reproduce themselves as truly and as abundantly as the typical forms with green foliage.

Variogated Ferns either for stove or greenhouse may be divided into three series: (1) Those with bright variegation which were introduced into European gardens from abroad, and of which *Pteris cretica albo-lineata* may be given as a type; (2) those produced in cultivation, of which *Pteris Mayi* is one of the most distinct; (3) those Ferns in which the variegation consists in the contrast of light green-coloured lines or patches on a naturally more or less dark background. The most distinct, as also the most useful, of this series is the deservedly popular *Lastrea aristata variegata*. If, for the purpose of simplifying their culture, we classify together all these plants, for which a temperature of 40° to 50° is sufficient in winter, we will find that although the list does not include those species with the most brilliant colours, it, however, contains the most popular and most useful variegated kinds. It is well known that in really well-variegated Ferns the character referred to is, with scarcely any exception, faithfully reproduced, and it is important to note that amongst exotic kinds the variegation, when fixed, is constant. Accidental variegation, however, is also occasionally met with among exotic Ferns of warm and cool temperature, principally among *Cyrtomium*, *Doodia*, *Lomaria*, and *Nephrolepis*, in which portions of fronds are more or less streaked and splashed with either white or creamy yellow, and it is quite possible that by careful selection we may eventually find the variegation in some of these plants permanently fixed, although it is not always the case.

When visiting Messrs. J. Veitch and Sons' nursery at Chelsea I recently noticed young plants of a very prettily variegated form of the semi-hardy Japanese *Lastrea atrata*, which, I was told, was raised by Mr. H. B. May, of Edmonton. This new-comer apparently possesses all the qualities for which the typical green form is so much appreciated. At the same place I was also shown a very prettily and regularly variegated frond of the justly popular *Doryopteris palmata*. This, however, is not yet entirely fixed, a small percentage only of the seedlings possessing the variegated character. The same may be said of a splendidly

variegated form of *Pteris serrulata cristata*, which forms a bushy plant of compact habit, each frond well crested and well variegated. These two last plants were raised by a Continental nurseryman, who, being a keen observer, does not give any stray seedling the chance of disappearing and being lost to Fern amateurs.

If we take variegated Ferns according to their decorative value, we may—as the best one of those adapted to cool culture—give first place to the beautiful

*PTERIS CRETICA ALBO-LINEATA*, which may reasonably claim to be the most distinct and useful of variegated Ferns, and the value of its decorative qualities is sufficiently shown by the enormous quantities of it which every year, and in all sizes, pass through our London markets. This Fern is usually considered a native of Japan. In contradiction to this, however, Lowe, in his excellent work, "New and Rare Ferns," published in 1871, says (p. 39): "It was introduced into England in 1860, having been received from the Botanic Gardens of Java." He also adds that some hundreds of plants of it had been raised at the Royal Gardens, Kew, from spores, and that every one was quite true, not a single normal green frond being found among them. It is also stated in the "Synopsis Filicum" that it had been gathered in Brazil by Dr. Glaziou. A thoroughly distinctive character of this variety lies in the great dissimilarity of its barren and fertile fronds. The former, forming the body of the plant, are broad and of a somewhat spreading habit; whereas the latter, much narrower in all their parts, are erect and well above the others, thus giving the plant a highly ornamental appearance. But it is the beauty and clearness of its variegation and its hardiness which no doubt has secured a well-deserved popularity for this remarkable Fern, which is particularly well adapted for the decoration of the dwelling-room, where, provided it receives careful treatment, it remains for a long time in perfect health, the broad silver bands which occupy the centre of its fronds and the bright green colour peculiar to their edges being extremely attractive. In

*P. CRETICA MAYI* we have a home-raised crested and also beautifully variegated form of *P. cretica* in which the dissimilarity of fronds, although very conspicuous, does not form a distinctive character. Although in this case the variegation is of equal brilliancy, the fronds are nearly uniform in size, and instead of standing erect, all the fertile ones partake more or less of the spreading character which in the typical plant is peculiar to the barren fronds, forming a plant of compact growth and habit similar to the several known crested, but green forms of this essentially decorative species. It also reproduces itself true from spores.

*P. c. NOBILIS VARIEGATA*, also a home-raised variety, differs from the preceding in its more compact and stiffer habit, the barren and fertile fronds alike being borne on stiff stalks of a brownish colour. Their leafy portion, also more important than in *P. c. Mayi*, is all undulated, of a bright green colour along the edges, with a broad white band in each leaflet, forming a striking and most pleasing contrast. Among the plants of larger dimensions equally well adapted for culture in the cool house we have

*P. MEMORABILIS VARIEGATA*, whose fronds, 20 inches to 24 inches long, are rendered very attractive by the centre of each of their numerous pinnae being of a bright pinkish colour, gradually, however, fading into white, a colour which they retain as long as they remain on the plant.

*LASTRÆA AKISATA VARIEGATA* is a plant of Japanese origin and a very handsome Fern, which needs no further proof of its excellence than the great esteem in which it is held by the public as a plant of first-class quality for indoor decoration. The variegation of its handsome leathery fronds, 18 inches to 24 inches long, is very effective. It consists of a pale green or whitish band running

all along the centre of each leaflet on a dark shining ground. It is worthy of notice that this variety reproduces itself freely and quite true from spores, and also that, although the contrast between the colours of the centre and of the sides of the leaflets is much more conspicuous in specimens which have been subjected to a little heat, this plant succeeds admirably in the greenhouse. Its constitution and the nature of its fronds render it one of the most enduring of all cool Ferns. It is even perfectly hardy in several favoured counties and remains outdoors uninjured through the winter in Cornwall, Devonshire and Somersetshire. In

*ATHYRIUM GORINGIANUM PICTUM* OR *TRICOLOR* we have another Japanese Fern of medium size, as hardy as the preceding one, but of a deciduous nature. Its fronds, which are abundantly produced from a fleshy underground crown, are very graceful, though very brittle, and particularly striking on account of their pretty elaret-coloured stalks, which form a most pleasing contrast to the bright grey colour of the leaflets disposed on each side. These are furnished throughout with a central white band running the whole length of the frond, and is as effective as in the better-known *Pteris tricolor*.

*DICTYOGRAMMA JAPONICA VARIEGATA*, a very distinct and hardy Japanese plant, may also be classed among variegated Ferns, for, when freshly developed, its fronds, which are produced from a thick, fleshy, underground rhizome, show unmistakable signs of variegation, which, however, gradually disappear as maturity is attained.

It would be most interesting to know whether some of the variegated forms of British Ferns which were best known some twenty-five or thirty years ago are still in existence, and, with a view to helping in ascertaining where they may now be found, I will here give short descriptions and a few particulars respecting their habitats, &c., according to E. J. Lowe's authority, as given in his excellent work, "Our Native Ferns."

*ASPLENIUM ADIANTUM-NIGRUM VARIEGATUM*, so named by G. B. Wollaston, is said to be a beautiful variety, normal in outline, its fronds being striped symmetrically with white. It was found in Yorkshire and in Guernsey by the late Mr. C. Jackson.

*POLYPODIUM VULGARE VARIEGATUM*.—Of this, two distinct forms were said to exist formerly in British collections: one with sharp pointed fronds, pretty distinctly striped with yellowish white stripes, found at Oldstead, Yorkshire, by Mr. C. Monkman, of Malton, and another found near Cark, Lancashire, by Messrs. Stansfield. The fronds of this form, nearly normal in outline, are of a leathery texture and marbled above with yellow blotches. Neither of these Ferns, we are told ("Our Native Ferns," vol. i., p. 53), proved constant under cultivation.

*SCOLOPENDRIUM VULGARE VARIEGATUM*.—Several forms of this plant have been known in collections, the principal ones being variegatum Claphami, a dwarf plant found by the late Mr. Clapham in North Yorkshire. Its fronds, normal in size, but slightly dilated at their extremity, are sometimes beautifully variegated with white. Another form called variegatum Willisoni, also a native of North Yorkshire, is also of dwarf habit, and its fronds are variegated with yellowish white. In both cases, however, the variegation is given as "only sub permanent." According to Lowe, *S. fissum* variegatum and *S. variegatum crenatum* are, or were, two handsome forms: the former with fronds narrow at the base and wide near the summit, but becoming rapidly acute to the tip, and differing from *S. fissum* only through its being variegated; the latter, a very fine variegated form of *S. crenatum*, with fronds forked at their summit and about 7 inches in length. The best variegated form of the common *Hart's-tongue*, however, appears to be the one named after its fortunate discoverer, Mr. Elworthy, and

is described as a "handsome, permanent variety, of a normal form and much variegated."

*POLYSTICHUM ANGULARE VARIEGATUM*.—The soft Shield Fern has also produced several variegated forms, which are described in Lowe's excellent work as having been in British collections. One found near Littlehampton, Sussex, called variegatum pramorsum, has its fronds furnished with pinnae of various dimensions and forms and pinnules spiny-toothed and very irregular. Another form named variegatum-eristatum, originally found near Southampton, has fronds normal in all their parts, except that their summit as well as the extremity of their pinnae are crisply tasselled; while another called variegatum-eristatum, and found in the Isle of Wight, has fronds 12 inches to 18 inches long, with thick, narrow, undulate pinnae and crisped pinnules. In these three varieties, all of which have been discovered by Mr. G. B. Wollaston, of Chislehurst, the whole plant is said to be beautifully variegated with cream colour during the spring and early part of the summer, but whether the variegation is conspicuous or not during summer and autumn is not stated.

Besides the plants above described there are several other well variegated Ferns, such as *Pteris argyrea* and *Victoria*, *Adiantum cuneatum* variegatum and *macrophyllum albo-striatum*, and others, but although these may exist under cool treatment, it is well known that they do not really flourish unless they are subjected to a warmer temperature. With the exception of *Athyrium Goringianum pictum*, which loses its foliage during the winter, all the above named plants will help to relieve the monotony of the cold fernery at this time of the year, as a temperature of 40° to 45° is all they require, especially when they are planted out, for we may here call the attention of intending cultivators to the difference in point of hardiness between the plants grown in pots and those planted out. The latter possess over the former a great advantage, inasmuch as their roots, even if only a few inches below the surface of the soil, are protected against the action of cold; whereas the roots of the plants grown in pots are readily affected by the more or less sudden changes of temperature from which the delicate texture of the extremity of the roots in immediate contact with the pots cannot fail to suffer. It may be safely asserted that a Fern which thrives in a winter temperature of 40° when planted out requires when grown in a pot 45° to 50° to grow equally well; hence the obvious advantages of the planting-out system. DOODIA.

*Adiantum Farleyense*.—This beautiful Fern is not grown nearly so much as it deserves to be. Many gardeners find it a difficult subject to grow well, and some make the mistake of potting it in the ordinary compost for Ferns, viz., peat, loam, sand, &c. The former it does not like, but it will do well in good yellow fibrous loam, rough leaf-mould, and some coarse silver sand, with a few lumps of charcoal. Some recommend a little bone-meal to be added, but I never use it, preferring to give the plants liquid manure as soon as the pots get full of roots. The pots should be well drained, never allowing the plants to suffer from want of water, and never syringing overhead. Plants that are not satisfactory should be turned out of the pots as soon as growth commences, split up into single crowns and placed in 3-inch pots, moving into 5-inch pots as soon as the small ones get filled with roots. These will make nice little plants for house decoration in the autumn. I have some here now in 5-inch pots that were treated exactly as I have described with from twenty to thirty fronds on a plant. Many of the fronds are 20 inches in length. The temperature of a plant stove suits it well.—C. R. C. W.

GARDEN FLORA.

PLATE 1000.

LILIAM BROWNI AND ITS VARIETIES.

(WITH A COLOURED PLATE OF L. BROWNI LEUCANTHUM.\*)

THE *Liliums* of China and Japan have given the botanist a great deal of trouble owing to their

*Lilium Browni*, showing growth.

been calling *L. Krameri*, so that we had to fall back on the next oldest name for the present plant, which is *L. Browni*.

We are not now concerned about *L. Krameri*, but it is satisfactory to know that *L. Browni* of 1845 is still *L. Browni*, and that the picture in *THE GARDEN*, Vol. XXIX. (1886), p. 350, is *L. Browni* true, and not *L. japonicum*. In *THE GARDEN*, Vol. XLIII. (1893), p. 41, there will be found a most interesting account of the *Liliums* of China and Thibet, which is a translation of a paper prepared by M. Franchet and published in the French journal of botany. M. Franchet's description of *L. Browni* may fittingly be quoted here:—

*L. Browni*.—A Chinese species found in the island of Chusan (the home of *Chamerops Fortunei*); also on the hills around Kiu-Kiang, in the province of Kiang-si, Ichang, &c. It exactly resembles *L. longiflorum*, but its flowers are larger, being from 6 inches to 8 inches long in wild specimens, and the divisions of the perianth are tinged with violet (red-brown) on the exterior. The most reliable distinctive characteristic of *L. Browni* is the presence of a more or less dense down of small papillose hairs on the margin of the nectariferous furrow, and on the filaments of the stamens and frequently on the style.

*L. Browni* is not a popular Lily in England, because it cannot be established as we can establish, for instance, *L. auratum* or *L. speciosum*. It is, however, often imported in quantity, and finds ready customers among those who know its beauty and who are satisfied with the truly rich display it rarely fails to make the first year. It winters badly with us, no matter how one treats it. The most successful method I know of is to lift the bulbs in late autumn and keep them in a cold frame, burying them in new cocoa-nut fibre or light peat and sand till February.

Dr. Henry states that in Ichang, where it grows wild amongst the mountains, *L. Browni* produced, when well cultivated, as many as fifteen flowers.

*VAR. LEUCANTHUM*.—This is the third good garden Lily that we owe to the zeal of Dr. Augustine Henry, F.L.S., who held a post in the Chinese Imperial Customs till recently, and who during his stay in Ichang, in the exact centre of China, collected largely in the interests of botany. In 1889 he forwarded to Kew a small box of *Liliums*, and from these have flowered the beautiful *L. Henryi*, of which a coloured plate with the history of the plant was published in *THE GARDEN*, Vol. XL. (1891), p. 422; *L. Browni* var. *chloraster*, described below, and that represented in the plate herewith. This is a distinct and beautiful Lily, undoubtedly a form of *L. Browni*, the bulbs, habit, foliage, and other botanical characters being the same, but from a horticultural point of view it is greatly superior in its good behaviour under cultivation, that is so far as experience with it at Kew goes to show its character as a garden plant. It differs from all the other forms of *L. Browni* in having

white flowers, shaded a delicate yellow on the lower part of the segments inside, and in the broad base of its tube. It was planted in a bed outside at Kew in 1891 and left in the ground without protection till it flowered last year. The bulbs when they arrived in 1889 were no larger than chestnuts; when lifted a short time ago some of them were as large as a man's fist. When in flower last August the tallest had a stem 4 feet high, green, the largest leaves 4 inches long, an inch broad, with three distinct nerves, those near the flowers being much shorter and ovate in form. The characters of the flowers are well shown in Mr. Moon's drawing; the largest were 6 in. long and the inner segments were over 2 in. wide, the reflexed portion of the segments comparatively short. Mr. Wallace, of Colchester, agrees with me that this is one of the finest of Eastern *Liliums*.

*VAR. CHLORASTER*.—This plant first flowered in the open air at Kew in 1891, when it was described by Mr. Baker as "a well-marked variety of *L. longiflorum*, with flowers resembling *L. Browni*." He shortly afterwards identified it as a form of *L. Browni*, and described it in the *Gardeners' Chronicle* in August, 1891, under its present name. It came, as already stated, along with *L. Henryi* and the plant herewith figured. In stature and general appearance it resembles the variety *leucanthum*, from which, however, it may be distinguished by its brown-tinted stem, narrower leaves and less nodding flowers. As its name signifies, it has a green tinge along the keels of the segments, which is broadest and most conspicuous inside the flowers. Until *leucanthum* flowered, we thought *chloraster* a first-class Lily. In its behaviour out of doors it has been quite as satisfactory as *leucanthum*. It may be worth recording that a good judge of *Liliums* suggested that these two varieties may have originated from a cross between *L. Browni* and *L. auratum*.

*VAR. OBOVATUM*, which was first described by Planchon with a figure in "Flore des Serres," t. 876 (1853), is now recognised as a variety only of *L. Browni*. It was figured in the *Botanical Magazine* in 1813 (t. 1591) as *L. japonicum*. It differs from the type in having a whitish or yellowish bulb (in the type the bulb is brown), narrow scales, green stems, thinner, less glossy leaves, and the flowers, which are smaller, are not so much tinged with red-brown. It is rare in gardens.

*VAR. PLATYPHYLLUM*.—Mr. Baker found among the specimens collected by D. Henry those of a *Lilium* with flowers like those of *chloraster*, but with anthers 1 inch long, whilst the stem was only 1 foot long, though the leaves were broader. It may be among the bulbs received at the same time as *L. Henryi*, &c., as some of them have not yet flowered.

*VAR. VIRIDULUM*.—This was introduced and flowered by Mr. Ware, of Tottenham, and described

Bulb of *Lilium Browni*.

multiplicity of forms, the result of long cultivation in the gardens of China and Japan. These cultivated forms have been introduced into Europe, and when they come to be compared with each other and with their progenitors, the wild types, it is not easy to classify them. This accounts for the error that was made in regard to *L. Browni*. Some time previous to 1845 a Mr. F. E. Brown, nurseryman at Slough, flowered a *Lilium* which he named after himself and distributed. Botanists, however, decided that it was *L. japonicum*, a species described by Thunberg, the Dutch botanist, many years before, and this view was accepted until lately, when the French botanist Franchet pointed out that true *L. japonicum* has pure white, open, cup-shaped flowers and lanceolate, distinctly stalked leaves, and probably has never been seen alive in Europe. Mr. Baker, of Kew, has arrived at nearly the same conclusion, but he recognises Thunberg's plant in what we know as *L. Krameri*. He wrote in 1891:—

We used to think that this (*L. Browni*) was the *japonicum* of Thunberg, but when Mr. Elwes was preparing his monograph the authorities of the museum at Upsala kindly lent us Thunberg's type specimen, and we found, to our surprise, that it was not this species, but what we had

\* Drawn for *THE GARDEN* by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by Guillaume Severeys.

by Mr. Baker in 1885. It has very short, broad leaves, cream-coloured flowers, only slightly tinged with red-brown outside.

Cultivators of *Liliums* may here be reminded that many of the species will ripen seeds if the flowers are fertilised, and from these quantities of flowering bulbs may be raised in two or three years. There is a large batch of *L. Henryi* at Kew, some of which will probably flower this year, and they are only fourteen months old from Kew-ripened seeds. A similar batch of the rare *L. formosanum* was raised at Kew three years ago, many of which flowered when a year old. The bulb scales also may be utilised for propagating.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**FRENCH BEANS.**—Fresh sowings of these should now be made, and, with lengthening days and increased sun heat, the yield will be better. In addition to Osborne's Forcing and Syon House, Newington Wonder and, where head room is plentiful, Canadian Wonder may be sown, small batches of each affording a succession, particularly if a little more heat is given to some than to others. The 6-inch pots may also now be replaced by those 8 inches in diameter, and the compost made a little stronger and richer than for the earlier lots. Six Beans in each pot are ample; therefore, when germinated reduce to that number. Crowding is ruinous. If a Cucumber or Melon pit can be spared, Beans do capitally in such positions, but the bottom heat should not exceed 75°, 70° as a maximum top heat suiting well. Where no other convenience exists than pits which have to be watered by removing the lights from the outside, I would advise sowing the Beans in 8-inch or 9-inch pots, and plunging them in the warm leaves and litter, as grown in this way the foliage is less rank and flabby, and suffers less from removing the lights for watering. When a good quantity of bloom has set, pinch the leads, in order to strengthen the plants and improve the crop. An effectual method of supporting Beans in pits is to place stout sticks at each end and in the centre of each row, and to carry thin twine from one to the other.

**PERMANENT SEAKALE BEDS.**—The crowns of these will now readily respond if covered first of all with Seakale pots, and afterwards with half leaves and half stable manure, not too decayed, treading the material well in between the pots, and allowing a top covering of at least a foot. A testing stick should be thrust in and examined occasionally. Where there are no pots the stools may be surmounted by stout stakes, bent over and secured at the tops, the heating material being piled round and over them. Rhubarb may also be forced in a similar way. Beds of Seakale intended to supply the last lot but one should also be covered with a good thickness of leaves, these being kept from blowing about by a layer of straw. Treated thus, growth will come on gradually, and be ready for cutting as soon as the pot-covered crowns are finished.

**PARSLEY.**—This is most in demand at the worst period of the year, and much forethought is requisite to keep up a supply in large places. If the roots which have been protected in pits or frames have been picked so closely that a scarcity is apprehended, large boxes may be filled with soil and the roots laid in thickly, the boxes being then placed in a temperature of 60°. Growth will soon follow, and a sufficiency be had until that in the pits again springs into growth. A few boxes may also be sown in heat.

**ONIONS AND LEEKS.**—Where extra large and early Onions are required, seed of such sorts as Cranston's Excelsior, Ailsa Craig, or the Wroxton may now be sown in heat. Boxes may be used, the seed being sown on a firm surface of good holding loam placed over a good layer of well decomposed manure, merely covering the seed and afterwards placing the box in a warm house averaging 60° at night, sprinkling with a fine rose or

syringe, and elevating them well up to the glass. Small pots, however, are preferable, sowing a few seeds in each, and leaving the most central plant in each pot when thinning out. They must be kept in heat for some weeks after germinating, being gradually hardened off in April. Leeks for producing extra large specimens may also be sown in the same way and treated similarly, using the richest soil obtainable, and only sifting that which covers the seed. A good strain of the Lyon cannot be beaten either for size or quality.

**SPINACH.**—A warm, sunny border should now be utilised for sowing a few rows of this vegetable, as it is very hardy and quickly germinates. This will be ready for gathering by the time the earliest sown winter batches are over. The latter can then be cleared off the ground, manure dug in, and another crop sown. A large breadth at this date is not needed, as Pea sowing will soon become frequent, and Spinach may then be sown between the rows. As soon as beds of winter Spinach are cleaned and hoed, a dressing of artificial manure should be given to assist growth.

**BRUSSELS SPROUTS.**—Seed for the production of very early sprouts, say at the end of September, may now be sown. In cold, exposed gardens, however, sowing should be postponed for three weeks later. Where the demand is small, a good-sized box will suffice for sowing the seed in, placing it in a warm greenhouse and eventually pricking out the young plants into larger boxes or in a frame on a mild hotbed. No better site can be selected for early Brussels Sprouts than that from which Celery has been dug. If this is trodden as soon as dry enough and retrodden previous to the plants being put out, the sprouts will be hard and of medium size, the reverse of what would be produced by a quantity of fresh manure. Later crops need more stimulants. Good sorts for early work are Northway Prize and Paris Market. Where Carrots are forced in frames the sprouts may be sown between the rows, and transplanted when of sufficient size.

**SPRING CABBAGE.**—Crops of this important vegetable growing in all but the heaviest soils may now be hastened on by the use of the Dutch hoe between the rows and by slightly earthing up the stems. On soils inclined to be cold, a sprinkling of guano applied broadcast before hoeing takes place will help the plants greatly, and on fairly warm soils any approved fertiliser will answer. All yellow and rotten leaves should first be removed, and if gaps through death or deformity abound, they should be made good by the use of an outside row, taken up carefully with a ball of soil attached, and planted firmly. As a safeguard, it is always well to sow a little seed of an early variety in a box or pan, as they often do good service, and if not wanted the labour is not much. Early Ellam's, Cocoa-nut, or Earliest of All are good and certain sorts for the purpose. Enough seed for a couple of rows of Enfield Market or Early Rainham may also be sown, this following the first named, and continuing in usable condition for a good time.

**CARDOONS.**—These will now come in well for a change, and will help out other things if a good quantity were stored away in a cool shed on the first appearance of sharp frost. Litter put over the plants in the open ground is sometimes depended upon, but it often proves useless and the Cardoons perish. I have seen them hung up by the heels in the Onion shed and remain sound for some weeks. These are impoverishing things and rather troublesome to grow, but if the seed is sown later in the season—say the middle of April—the plants attain to a very useful size and can be managed as easily as Celery. The seed is best sown in small pots and the plants grown on in warmth, afterwards hardening off and planting out with the ball intact. Feeding on a liberal scale when growing is necessary.

**COOL-GROWN RADISHES.**—A sowing of Wood's Frame or French Breakfast may now be made in a cold frame or pit in light friable soil. These will be ready for pulling by the time the supply from hotbeds and early Potato frames is exhausted. If a single light frame only can be

spared, mix the seed of the two varieties together, and so secure a pulling of each. Cover at night with long dry litter or Bracken and give no air, even during sunny days, till the young seedlings appear, when liberal thinning and abundant ventilation will be necessary. A sowing may also be made in a warm sheltered corner, and, if possible, on a slightly raised bed, sowing the same sorts and covering at once with litter. This must remain on until the Radishes appear, and then be removed each frost-free day, being again replaced each evening. Acres are thus grown in the neighbourhood of London.

**HARDY GREENS.**—The majority of Coleworts that were planted out sufficiently early to form good solid hearts will ere now have been cut, but autumn-planted batches, which will have to be used as ordinary greens, are yet numerous. As, however, after this date these are liable to bolt, the best plan is to lift them carefully and lay them in behind a north wall, in which position they will keep fresh and good for some weeks longer. The ground can then be manured and dug in readiness for Peas, Beans, or other early crops. As soon as the severe frost disappears, quarters of Scotch Kale should be gone through and all the lower leaves removed from the stems. This will induce fresh young sprouts to issue from every joint, these proving most useful during April when there is a scarcity.

**SPRING BROCCOLI.**—The past few weeks have been very trying to some varieties of spring Broccoli, these being often so damaged just beneath the crown as to prevent the heads from swelling to half their normal size. If they have not yet been protected by hay-bands or Bracken worked freely in amongst the stems it should now be done. Where heads of the Leamington Sulphur or Early Penzance have already grown to the size of tea-cups, lifting had better take place, removing them with stem and root to a cool shed and laying them in leaf-mould or other dryish soil and giving a slight top covering of dry littery material. These, though small, will prove most acceptable in the dining room. Where Cooling's Matchless is grown for March supply it should now receive some protection in a similar way.

J. CRAWFORD.

### FRUIT HOUSES.

**PINES—EARLY FRUITERS.**—A few of the strongest plants should be started, selecting those with thick stems and of good sturdy habit, placing them in a closer house or pit with more bottom heat. For this batch I prefer a small, close house with every provision for a nice genial heat. Admit every ray of light. The glass should be clean and new material placed in position for plunging, this being made firm. Should any doubt exist as to over-heating, place the plants on the surface, having trial sticks in the heating material to test warmth. Plunge the plants when the temperature is falling and the heat at about 90°. For reliable fruiting, Queens are the best for the time named, and those with a knowledge of Pines can readily judge the best plants. If kept at rest during the winter they often start or push up the fruit at once when placed in their fruiting quarters; whereas if kept too warm and growing they are much longer about. The plants have longer leaves, are often loose at the collar, and need more care in plunging. If at all loose, remove some of the lower leaves and top-dress the plants with large pieces of turfy loam, well ramming the material close to the stem. Should this fail, I have used a short stake at the base to secure the plant to, ramming the soil firmly. If bottom heat is supplied by hot water, the plunging is simplified and there is less fear of burning, as with fresh tan, leaves or manure. Even with hot water it is well to maintain a regular temperature, as fluctuations cause uneven growths, and the plants do not take regular supplies of moisture and food. As soon as the plants are well settled down, give liquid manure or guano water, but free from thick matter. Before applying manures, if the balls of the plants are dry, water with tepid

water and get the whole mass saturated before applying stimulants. The temperature of the house for the early fruiting plants should not be too high at the start, 70° being sufficient in most houses, with a rise of 10° by sun heat early in the day. The night temperature may be a few degrees lower, 65° being high enough in severe weather. To prevent excessive firing cover the outside glass with a warm covering at nightfall, and in fine weather increase the atmospheric moisture, damping all parts of the house except the hot-water pipes. Keep the moisture at this time of the year out of the hearts of the plants, and give more moisture in all parts of the house as the days lengthen.

**SUCCESSIONAL PINES.**—The cream of the plants having been picked out for early fruits, the successions will be left in an irregular condition. As these need less attention in the way of heat and moisture, it is not well for another month to force into growth. Any plants showing signs of starting may have the warmest position and a little more moisture at the root. It is not advisable to remove these plants if they can be kept quiet for a short time longer—rather have as many for succession as possible. The temperature should not be raised much, as at the time of writing the weather is very wintry. At the time these notes are penned, 60° at night are ample, and 65° to 70° by day. Ventilate during bright sunshine, with occasional dampings down. Strong suckers potted up early last fruiting season should be kept moist. These will not have rested during the winter, and will give a good return next August. If kept growing place them near the pipes, and with more moisture they will be in good condition to pot later on.

**GENERAL STOCK AND POTTING.**—Old plants should receive more atmospheric moisture, with a genial bottom-heat and a slightly raised day temperature if the weather is bright. Make preparations for potting. The strong plants will require a good shift, the largest into 10-inch or 12-inch pots. Get the pots in readiness, washing and placing them ready for use. Avoid using new pots if others well seasoned can be had. Well drain the pots, using clean crocks, and for the larger plants a special compost as rough and fibrous as possible for the larger plants. This should be placed in bulk under cover in the potting shed, so that it is in good condition by the time required. For small suckers smaller pots and finer material will be wanted, and should be got ready for repotting next month. As fresh heating material is needed in large quantities next month for both succession and other small stock, collect it into large heaps for the heat to go through the whole mass, turning it frequently to dry the materials. This does not apply to tan, but as manure and leaves are often used for small stock, it should be prepared as advised to get rid of steam and violent heat. Small plants may be kept from 5° to 10° lower than succession plants, but should any plants have got sour or are sickly, repot earlier than advised, having got both the potting and plunging material ready before beginning the work. Use plenty of drainage material in the soil to keep it open, and keep the pits close after potting, giving moisture sparingly at the roots for a time.

**STRAWBERRIES IN POTS.**—Another lot of plants should now be prepared for forcing, and as only few can devote a house to Strawberries, they have to be forced in a variety of ways. For forcing to fruit early in April there is no more reliable kind than *La Grosse Sucrée*, which forces well, as it often only produces a single well-matured crown, and the flower-stalk comes well out of the centre of the plant. The flavour is excellent, being very sweet. This variety does not make so much foliage as some others, and therefore the plants may be grown more closely together. I would also advise *Royal Sovereign* for early April fruits. The fruits are large, flavour brisk and luscious, and if required to pack for long distances, superior to *La Grosse Sucrée* in that respect. Plants placed in fruit houses at this date should be thoroughly cleansed before going on shelves,

also the foliage dipped to get rid of any pests lurking in the foliage. Use sulphur freely for the destruction of mildew. Very little moisture will be required at the start, but in fine weather syringe the plants overhead freely. The best results are obtained by allowing the plants a long period at the start. Any attempt to hurry them will end in failure; whereas forced slowly there will be a good return. Many can devote shelves in houses just starting to Strawberries, and treated thus they set well and finish little inferior to those in the open. The plants placed in a mild bottom heat late in the year will now be showing flower-spikes freely, and may be given more warmth, also a rise of 5° and as light a position as possible. Syringing must cease as the flowers expand, and in mild weather give a dink of air daily. At this early date fertilisation of flowers will be necessary. This should be done at midday in bright weather. Plants just coming into bloom should be fumigated several nights in succession, as this work cannot be performed later whilst in full flower. As soon as a good set is secured, reduce the fruits to eight or ten at the most, as more will not finish well. Syringe daily with tepid water, raise the temperature, and give weak liquid manure. To push on a few very early fruits of such kinds as *Vicomtesse*, which will do well in a moist house, after thinning, the plants will make quicker progress if moved into *Pine* stoves or houses with a temperature of 60° to 70° by day with more warmth. More food can be given till the fruits commence to colour.

**CUCUMBERS.**—The plants that have been giving winter supplies will be less vigorous now, and require every encouragement until the newly-planted ones come into bearing. Give rich surface dressings of bone-meal and soil warmed before placing on the surface, also liquid manure. As long as the plants send out new growth a supply will be maintained, but when this ceases it is useless to give food as advised. Rather hasten the succession plants, and by stopping at the earliest moment get a few fruits to form a succession. Another sowing should be made for later use, as often in private gardens there is a greater demand in the spring for Cucumbers, and as there is no advantage in growing exhausted plants, the house or pit in which the winter stock is will be available. Plants coming into bearing should not be allowed to carry too much fruit at first. They must be assisted frequently with rich surface-dressings, a steady bottom-heat of 80° and 65° to 70° at night, with a free rise of temperature by day, with a free amount of moisture in all parts of the house, hastening growth. If practicable, cover the glass at night to maintain warmth without excessive firing. At this date little air will be required if due attention be paid to moisture; indeed, cold draughts of air mean red spider, thrips, and green-fly. G. WYTHES.

## ROSE GARDEN.

### PLANTING OF DWARF ROSE STOCKS.

WHILE it is quite right to plant our hedge Briers for standards and half-standards during the autumn or early winter, I certainly think we are wiser in delaying the transplanting of dwarf stocks until the middle of February and March. Such at any rate has been the result of my experience and observations. Our standards have been more or less exposed to cold from their first growth in sucker form, but, although we propagated the cuttings of all dwarfs from wood equally exposed, they have been kept from light and weather influences during the whole period they were forming stocks. Nor, as a rule, has the wood utilised for stocks had any frost; certainly none of any severity where propagated at the most suitable time. This, then, combined with the more tender or softer bark formed beneath the surface soil, renders

our dwarf stocks rather susceptible to a severe frost. More especially is this the case with the *Manetti*, and I have frequently seen a bed of good stocks crippled by frost when planted in the autumn. The cutting *Brier* is a little hardier; so, too, are the seedlings; but, nevertheless, I prefer spring to autumn planting of all dwarf Rose stocks.

A hint or two upon these is suggested by a complaint from a friend that small seedlings had been forwarded to him, whereas he required some fit to work upon during the coming summer. A two-year-old seedling of the thickness of a small knitting-needle is most suitable, but they may be of less diameter than this, and still swell quite sufficiently to be safe for the majority of *Teas* and *Noisettes*, also for the smaller of the *Hybrid Perpetual* buds. It is during the last few weeks of July and August that they swell so rapidly, and a summer shower makes a vast difference. If we plant stocks of seedling Briers that are large enough for budding now, say about the size of a lead pencil, they are almost sure to be much too stout for *Teas* to be worked upon with any safety. A coarse stock, particularly one that continues to swell so long after the bud is inserted, is apt to smother the latter. Cut off the tips of the longest roots of these, and do not fear to serve all stocks in the same way. A seedling treated thus is little inferior to a well-made cutting *Brier* stock.

In planting, we must take into due consideration the class of Rose we intend working. If it be some dwarf and close-growing variety like *Catherine Mermet* or *Devoniensis* from the *Teas*, *La France* and *Augustine Guinoisseau* from the *Hybrid Teas*, or *Louis Van Houtte* and *Marie Baumann* in the *Hybrid Perpetual* section, then a distance of 9 inches in the row, with the latter 3 feet apart, is ample. But we need double the space for *Gloire de Dijon*, *Rêve d'Or*, *Margaret Dickson*, and others, taking care to give a mid-way position to the ordinary growers. Dwarf stocks made from cuttings are best planted as shallow as we possibly can, so that they will remain upright. Then choose the first opportunity when the soil can be worked easily to draw it up to and around them in the same manner as cultivating *Potatoes*. This not only supports them, but we can so easily get the bud upon the crown of the root in due season. The raised soil is easily removed, and we also find the underlying bark of the stock in a softer condition for working, and not so liable to split when inserting a bud of large size. R.

### AMONG OUR INDOOR ROSES IN FEBRUARY.

IN all cases, even in unheated houses, this is one of our busiest months. It is with the main batch of our pot Roses that I wish to deal at present, and here we are certainly at the most critical period of their existence unless they are more than usually backward. All of them have growth, many already showing bud, and others coming into bloom. This week I was looking over a garden where pot Roses are not so well done as they should be, seeing every facility of heat, room, and labour was available. No wonder that many condemn a pot Rose as producing only an occasional bloom of presentable appearance in cases where they are neglected in the present stage. Once allow insects to gain a hold, or only once give the plants that disastrous check which is the outcome of those extreme measures one is sometimes tempted to use in exterminating insect enemies, and we may look for an annoying failure with

the present crop of bloom. Nor should we be too generous with liquid manures. We are apt to look upon Roses as particularly hungry plants. This is correct enough, but we must not forget that we have given them a highly concentrated food in the rich potting soil used; therefore, to supply liquid manures freely and before the roots have been able to take up any appreciable quantity of the food in the soil is not a wise proceeding. Allow the new roots to work into this in the healthy and free way they delight in doing, and leave liquid manures for plants in partially exhausted soil, and also as a sustaining aid to strong growth later on.

Sudden changes of temperature are another source of many failures. It is somewhat difficult to ward against this. On January 25 and 26 we had very keen winds and no sun; the following morning (Sunday) there were about 15° of frost. Now this was immediately followed by a bright and clear sunshiny day; consequently, the house with barely warm pipes was up to a temperature of 80° and 90° by 11 o'clock. Air could not be afforded, as the wind was uncertain, and a draught of that kind was almost sure to start mildew. All we could do was to keep the place moist and the pipes as cool as possible; in fact, the fire was allowed to go out. It was difficult to keep the temperature high enough at night and early morning, also upon more than one occasion during the previous few days, and then in the space of a few hours we find an equal difficulty in keeping the heat sufficiently low and avoiding the inlet of any cold air. We cannot hope, nor do we need, to keep up a uniform temperature; but Roses in full growth and tenderness cannot be subjected to extremes with impunity. Some of us, I fear, are too anxious to see our plants entirely free from insect enemies. It is very nice to have them so, but I venture to say we can hardly secure this and avoid over-doing them with liquid insecticides or fumigation. Insects spring from all quarters and at almost any time, and while we are right in endeavouring to keep them away entirely, I fear we often err almost as much in this respect as by allowing them too long a spell of peace. If we use the syringe judiciously and a weak insecticide, there is little fear of insects gaining any seriously injurious hold. I am not now alluding to scale; this must be exterminated, or at any rate stubbornly battled against, and no time is more favourable than while the wood is dormant. When young growth has commenced we can seldom deal with scale effectively. To give a check, whether by atmospheric extremes, mistakes in watering, or when cleansing our plants, has far more to do with the dropping of buds, their turning black as soon as visible, and also failing to appear upon well-matured wood than many apparently realise, if we are to judge by the treatment accorded in many private gardens. Another error of no mean consideration is too great a hurry during the first breaking of new growth. We must wait for the roots to come along in due order, more especially when the plants are turned out of pots. In pots all of the plant and soil are subjected to the same influence of heat, and for this reason will stand rather sharper forcing. R.

*Rosa camelliæflora* has been on my west wall ten or twelve years and never bloomed till 1894. I should not have had patience enough to keep it so long but for the beauty of its evergreen shiny foliage. It is now 10 feet or 11 feet high. Mr. Ellacombe maintains that it is the Cherokee Rose (*R. sinica*, *B.M.*, 2847), but the leaves of that are strongly serrated. Mine, which I enclose, are smooth and the blooms more cup-like.—G.

## TREES AND SHRUBS.

### RUBUS AUSTRALIS.

THE Brambles are essentially plants of the northern hemisphere, and although common on the mountains of the tropics, very few reach the temperate regions of the southern world. In New Zealand several of our European species have become perfectly naturalised, amongst which are *Rubus laciniatus*, one of the most beautiful of all Brambles; *R. leucostachys*, pubescens and discolor, the last of these having invaded every part of the colony. The only species, however, truly native of New Zealand is *Rubus australis*, the subject of the accompanying illustration. It is a species of particular interest, being, in the first place, one of the largest, perhaps the very largest of all Rubi. In its native country it climbs to the top of the loftiest trees, often, according to Sir J. Hooker, associated with a climbing Fern—*Lygodium*.

*Rubus australis*. From a photograph sent by Miss Hunt, Southfield, Paignton, Devon.

Another feature of interest in connection with it is its extreme variableness. So far as the foliage of its different forms is concerned, it varies from a practically leafless condition to one possessing a wealth of lustrous deep green leaves of large size. It is not strictly correct, however, to speak of it as "leafless," for the leaves are always there, being made up of three, five or more leaflets; but in the particular variety alluded to (and the one represented in the engraving) each leaflet is reduced to a long spiny petiole and midrib, terminated by a small lanceolate blade a quarter of an inch to 1 inch long. In other varieties the leaflets are of ovate outline, usually more or less cordate at the base, some measuring 2½ inches in length and 2 inches in width, others as much as 4 inches long by one-fourth as much in diameter. The margins are always coarsely serrated and the under surface frequently pubescent. The stem is occasionally quite smooth and never so formidably armed as the petiole and midrib of the leaf, which are thickly set with recurved prickles, these serving the double function of protection and support.

I am not aware of this *Rubus* having flowered in this country. Perhaps it has, but its flowers

are borne in large branching panicles and they are small (less than half an inch across), either white or faintly pink-tinged and fragrant. They are also unisexual, the male flowers being distinguished by a conspicuous ring of numerous stamens, which are almost absent in the female flowers. The species is spread over the North and Middle Islands, occurring most abundantly on the borders of forests. It is one of the plants known to the colonists by the name of "lawyer," and the Maori name is *Tataramoia*.

So far as the larger part of England is concerned, it cannot be described as strictly hardy. It may on a sunny wall be grown for some years, but sooner or later a frost comes which is too much for it. It is perfectly at home on the south and west coasts and in similarly favoured places. With Canon Ellacombe at Bitton it is, I believe, a great success. A plant on a south wall at Kew, which got to be of good size, was killed a few winters ago. It is now replaced by a smaller one, and is also represented in the large temperate house. It is indeed in winter gardens and cool conservatories that it will in most parts of the country have to be grown. Planted at the foot of a *Panax* or other New Zealand tree and allowed to grow over it, a cha-

acteristic bit of the native flora might be reproduced. W. J. BEAN.

## KITCHEN GARDEN.

### BROAD BEANS.

As early in February as the ground can be got into a free working state the first sowing of Broad Beans ought to be made. Better, however, wait till the middle of the month or even later if the soil cannot be got into a suitable condition before then, as seed that is puddled in thus early cannot be depended upon to germinate properly, and even if the plants did come up fairly well they would make but poor progress. If wanted extra early, then by all means try to have them ready for use as quickly as possible, even if this means the adoption of the very old plan of raising enough plants in pots under glass for a few short rows, hardening off and planting these out before they become badly root-bound. As a rule, though, Broad Beans are not greatly esteemed at the tables of the wealthier classes, one or two dishes being about

all that are asked for. Consequently it scarcely pays to take so much trouble with the early crops nor to devote valuable space in sheltered borders to their culture. If any are grown in such positions, then it ought to be a dozen or rather fewer short rows of Beck's Dwarf Green Gem. This variety may not be quite so early as the Early Long-pod, but it is altogether superior to it in point of quality and of a size and colour that find most favour. Very few owners of medium-sized to large gardens will tolerate fully grown Beans of the Long-pod or Broad Windsor types on the dining-table, and if they have them at all they must be small or very young, and when gathered and cooked thus early they are of a flavour that working men would consider decidedly objectionable. In Beck's Green Gem we have a dwarf spreading variety that produces small pods filled with green seed very freely, and these when properly cooked and served are not far removed from good Peas in point of quality. A distance of 2 feet apart is ample space between the rows, and the seed may be zigzagged in rather broad drills, a distance of 4 inches apart being then enough for the plants. For the dining-table or for my own use I would prefer to grow this variety for the successional and midseason supplies, sowing the seed on ground sloping southwards early in March, and more again, but in a cooler position, directly the last sown are showing through the ground. By the time the plants from the third sowing had ceased to produce there is every likelihood of enough of that class of Beans having been had for one season, but if late dishes were desired, more seed could be sown early in July, ridges between trenches intended for late Celery answering well for this crop, a single row being sown through the centre.

As it happens, my old favourite is far from being generally grown, and we will next discuss the merits of the few varieties that do find favour. As before stated, Early Long-pod is the earliest Bean I am acquainted with, and the best strains of this variety are remarkably prolific. A selection I once had from Mr. D. Thomson, and which he found the best at Drumlanrig, produced pods with the greatest freedom. They were scarcely large enough to please an exhibitor, but the lower ones touched the ground, and the haulm cropped to a height of 3 feet. The seed is moderately large and the quality good. Seville Long-pod is also early, and the pods are finer than those of the variety just mentioned, but they are far too sparingly produced, and, therefore, the variety is unprofitable. The Mazagans are later, but very hardy, the reason why they are so often recommended for autumn sowing. Leviathan or Aquadulee are more remarkable for the great length of pod they can be made to produce than for any other good quality possessed. Of the shorter-podded varieties, or Broad Windsor type, I prefer the Harlington Green, a slight improvement apparently on the old green form. In point of colour and quality, too, I think the green-seeded varieties are decidedly the best, but the white-seeded forms are also largely grown, both sorts succeeding better in hot weather than do the Long-pods. In each and every case there should be no leaving the pods hanging long enough for the base of the seed to become grey, and that whether the skins are slipped off before or after cooking or not.

Broad Beans fail quickly on hot, non-retentive soils. What they require is a good depth of moderately rich, strong soil, clayey loam suiting them well, though not if in a very lumpy condition at sowing time. Single rows of moderately strong growers may be disposed 2 feet

apart, the seed being sown sufficiently thickly to be sure of plants being eventually left 4 inches apart: but many still prefer the old plan of sowing in double drills. These double drills are drawn 4 inches apart, 3-foot intervals being allowed between them, that is to say, from double drill to double drill. In this case enough seed should be sown to be sure of having plants 6 inches, or rather less, apart in each line. Early in the year the seed need only be covered with 2 inches of soil, but later on they ought to be from 3 inches to 4 inches deep, or otherwise dryness may prevent or hinder germination. Three or at the most four successional sowings, the second being made before the first sowing is just coming through the ground and the others after the preceding sowing is showing, are usually ample. Very few growers can afford to water their rows of Beans during dry weather; they do not pay for the trouble, in fact; but the rows ought to be early and heavily moulded up, a mulching of manure further serving to conserve the moisture in the ground. As a rule, the moulding up—somewhat after the manner soil is drawn up to the haulm of Potatoes—is all the steadying required; but if extra fine straight pods are desired, then it pays to thin out and stake some of the plants, the best shaped pods only being reserved on them. Topping Broad Beans hastens the pod-filling and also gets rid of a plentiful crop of Beau aphid that usually collects at the point of each growth. W. I.

**Preparing for Onions.**—In getting the ground into order for this important crop two things must be borne in mind—a rich larder and a free admixture of something to prevent the inroads of the Onion maggot. Where time and labour are plentiful I would certainly advise discarding the ordinary plan of trenching, preferring to take out a very deep cavity at one end of the plot, and wheeling the soil to the opposite end, afterwards laying on rich manure in plenty, mixing therewith plenty of soot. Well work this in from top to bottom as the work proceeds, throwing the soil forward continually to the depth of the original trench. The Onions then get the benefit of the manure from the very start, which they require. Firmness being indispensable, light soils may be well trodden even now, more retentive ones being left till the surface can be broken down with forks in February.—C.

**Dwarf *versus* tall Brussels Sprouts.**—The value of a good strain of dwarf Sprouts is most marked when seen growing side by side with the tall kinds. I have a portion of both this year, and I have decided to give up growing the tall, big-sprouted kinds. Recently when looking these over I noticed that the tall-growing kinds had not a good sprout nearer than from 6 inches to 9 inches from the ground. On the other hand, the Dwarf Gem strain had good sprouts near the ground. Another recommendation of the dwarf strain is that it stands the frost better, as the leaves hang down and cover the stem. Again, the dwarf kinds do not want so much space. This last autumn I noticed Early Dwarf Gem had good sprouts a month earlier than the tall-growing; and now at the end of January I consider it will continue bearing as long as the tall-growing kinds.—J. CROOK.

**Celery and moisture.**—The note at page 40 draws attention to the good quality of Celery this season. In my experience it was never better. I do not mean so much for mere size, but for the crisp, nutty flavour of the heads and their solid growth. I am not inclined to go as far as "A. Y. A." and advise that very little feeding of any kind is required if a fair quantity of manure is given at planting time, as in dry seasons the plants when they attain a fair growth absorb the food more quickly, and rich food in the way of surface supplies is necessary, or there is a check,

with the result the plants bolt and those left are tough and flavourless. It may be thought, why should liquid manures be given more in dry seasons? because when given these the plants absorb the food more readily; whereas in a wet or dripping autumn the soil is not in condition and the plants are so full of growth that such aids are not required. My opinion is that a wet season is just what the plants like, provided there is good drainage and the plants are not moulded up too early, this latter being the reason of decay. I am not an advocate for giving a large body of manure at planting-time. This may be carried to excess, as the plants at the start cannot absorb such quantities and do not get the food at the proper time. If given liquid manure once in ten days growth will be solid and there will be no decay. In Celery culture the best results are obtained by varying the treatment according to the season. They certainly like a wet season if other requirements are attended to.—W. M.

**Standard-bearer Celery.**—Those who require a medium-sized Celery of first-class flavour would do well to give this variety a trial. It is one of the best keepers I have grown. For spring use I have found none so reliable. It is not large, but the flavour is all that can be desired. I have had this variety good well into May. I usually sow the seed early in April on a warm border, placing a frame over it till the seeds come through, and plant direct into the trenches. By this means I get late heads with little trouble. I lift early in March from the trenches and place in a cool place under a north wall or trees to check growth; by this means it may be had much later in the season.—S. H. B.

**Model Carrot.**—This is an excellent early variety and far superior to the old Shorthorn kinds. Last year I sowed this variety, and the older kind the first week in March on a warm border, and it was fit for use two weeks in advance of the older form. The roots of this variety are about 6 inches long, symmetrical in shape, thick at the shoulder, and stump-ended, the skin smooth and of a bright scarlet colour. For frame work it is excellent. I sowed this variety last August in the open for drawing in a fresh state during the winter months and the quality is all that can be desired.—W. S.

**Dwarf Erfurt Cauliflower.**—Of late years there have been many selections from this variety, and where it can be obtained true it is one of the best Cauliflowers ever sent out. It is a favourite variety on the Continent. I have grown the true type for some time, and it is well worth a trial by those who require early Cauliflowers of good quality. It is larger than Snowball, but when sown in heat it is nearly as early. I prefer to sow it in autumn and winter in frames or pots, as then the produce is finer than from plants raised in heat early in the year. This variety is of very dwarf growth, having a short leg or stem and broad, thick leaves, with a close, hard, white curd of splendid flavour. For later use the Erfurt Mammoth type is equally good.—W. M.

**Huge Onions.**—Are Onions 4 lbs. and 5 lbs. each in weight required? I think not. Of what use are such huge bulbs except for exhibition? The varieties Mr. Crews names are comparatively new, such as Ailsa Craig, Rousham Park, and the quite new to me New Mammoth Pompeii. I venture to think we can do without the last-named, as Onions 5 lbs. in weight will serve no useful purpose; these monstrosities should not be encouraged. I am not finding fault with these growers for improving the culture up to a certain size; for instance, one dozen weighing 12 lbs.; these are large enough for all purposes, as they may in time oust the Spanish Onions so largely imported into this country, and are, if not too coarse, useful as a winter vegetable. By growing to such dimensions as stated at p. 41 I fail to see their value, for I am sure such will never pay when the cost of production is taken into account. These huge bulbs will not pay the market grower. For shop windows or for exhibition exorbitant prices may be obtained for these huge Onions.

For sound, well-ripened large Onions there is a demand. Many of the older kinds, such as White Spanish, may be grown to a very large size with special cultivation. Some of the newer kinds may be termed good selections of the old. I am pleased to see this improvement in their culture, but we do not want coarseness. A few years ago the Tomato was taken in hand, and we had fruits 2 lbs. to 3 lbs. in weight, but they were useless, being flavourless and not at all freely produced.—GROWER.

## STOVE AND GREENHOUSE.

### FINE-FOLIAGED PLANTS FOR DECORATION.

THE demand for these seems to be ever on the increase, and gardeners are often put to serious straits to know how to provide a sufficient quantity for that purpose, particularly those who have only a limited amount of glass at their disposal to work up a stock. Where this has to be accomplished, it will be necessary to commence propagation as soon as possible. There are many plants with light graceful foliage that are well adapted for such work, and if these are taken in hand now, a good stock may be obtained by the time they are required for use. Plants of a hardy and half-hardy nature having light graceful foliage are numerous, while others of a dwarf compact habit render them most desirable adjuncts for edgings or covering pots, and those of a trailing habit are indispensable for mantel-pieces, slabs, &c. *Carex riparia variegata*, *Dactylis glomerata*, *D. elegantissima aurea*, *Phalaris arundinacea elegantissima*, and *Molinia coerules variegata* may now be divided and potted into various sized pots, according to the strength of the plants and the purpose to which they are intended to be put. *Eulalia japonica gracillima*, *E. variegata*, and *E. zebрина*, all very useful plants for furnishing rooms, should now be divided, and after being potted in a light rich mixture ought to be started in a gentle heat to induce them to throw up their slender Grass-like foliage, which when young is very pleasing. There are also several of the Bamboos very useful for this work, more especially those with small leaves and compact habit, such as *Arundinaria falcata*, *A. Fortunei*, and *A. Fortunei aurea*, all of which are readily propagated by division. Among the Grasses that are more tender will be found *Panicum variegatum*, easily grown in heat from cuttings. About half a dozen should be put into a 3-inch pot, filled with light sandy loam. When rooted the tops should be cut off in order to make the plants break close to the pots. *Carex europæa*, a light, graceful species, with narrow, variegated leaves, is easily propagated by dividing the roots; likewise *Carex variegata*, a dwarf kind. *Curculigo recurva* and *C. recurva variegata* are readily increased by dividing the roots. *Ophiopogon Jaburan variegatus*, *O. spicatus* and *O. europæus* are all useful plants. Of Ferns and Lycopodiums there is a goodly number. Those, however, with light graceful foliage and easy to cultivate are the most serviceable, such, for example, as some of the *Adiantums*, *Pterises*, *Lomarias* and *Davallias*. The *Selaginellas* most suitable are *denticulata*, *cæsia* and *Wildenovi*.

There are also numerous stove and greenhouse plants, with both plain and variegated foliage, that are most useful for indoor decoration, all of which can be grown without much trouble if due attention be paid to their requirements. Take the *Caladiums*, of which there is almost an endless variety of dwarf compact habit with medium-sized foliage. The old *argyrites* must on no account be despised, as there is no other with the same striking unique habit. *Le Nain Rouge* comes next, after which we may put *Marguerite Gellimer*, *Martha Lorforg*, *Comte de Germiny*, *Ibis Rose*, *La Lorraine*, *Isis*, *Ibis Rouge*, *Mme. Leon Say*, *Mme. J. Box* and *Mme. Alfred Magne*, all of which have very delicate telling

foliage. Of *Crotons* there is also a numerous assortment; those, however, with long, narrow foliage are the most useful for this purpose. Cuttings rooted in September ought now to be potted into 5-inch pots in order that the pots may be well filled with roots before they are used. Other cuttings should also be put in to supply plants of suitable size. *Aralias*, such as *Veitchi* and *A. gracillima*, should be grafted on *A. Chabrieri*, which can be easily increased by cuttings. *Dracenas* ought also to be propagated. To get well-furnished plants quickly, ringing is the best mode to adopt, but where small plants are required these are best produced from root cuttings. Those having narrow foliage are far preferable, as they are much more graceful. *Pandanus Veitchi* is so easily grown, that no place where there is a quantity of table plants required should be without a good stock of it. The smaller the young offsets are taken the better, as such make the best furnished plants. *Phrynium variegatum* is another plant useful for this purpose, and is easily propagated by dividing the thick fleshy underground rhizomes just as the plants commence to grow. *Pilea muscosa nana*, *Pellionia Daveauiana* and *P. pulchra* are also well adapted for mantel-pieces, hanging baskets, &c. *Asparagus plumosus* and its varieties are so easily grown, that no place is complete without a quantity in various-sized pots. They may be propagated either by seed or cuttings. The former mode is the surest, as with care good plants may be had in a short time. A quantity of *Myrsiphyllum asparagoides* should also be grown, as it is so useful for supplying greenery of a light delicate nature. It is quickly raised from seed or by dividing the roots. Some of the variegated Vines, such as *Vitis heterophylla striata* and *heterophylla variegata*, also *Ampelopsis Veitchi*, will be found serviceable in their turn. Palms form such a considerable element in this branch of horticulture, that no place can do without them. There are, however, some far more useful than others, and it is to these I wish to draw attention. In my opinion *Rhapis flabelliformis* must take a front place, not that this is one of the most graceful, but it is one of the easiest to cultivate, for it may be increased freely by the suckers sent up from the roots. Then there is its counterpart, *R. flabelliformis variegata*, a most desirable species. *Cocos Weddelliana*, *C. plumosa*, *C. flexuosa*, and *Romanzoffiana* are all good. *Kenias* of all kinds are very serviceable, as they will put up with almost any amount of rough treatment, but they should never be taken into the dwelling-house unless well rooted. *Areca Verschaffelti* is also a handsome Palm, but on account of its slow growth it will never become popular. *Geonoma gracilis* and *G. intermedia*, *Euterpe edulis*, *Thrinax elegans*, and some of the *Chamædoreas* are also useful, but, as a rule, those with large fronds are not serviceable. As most of these are obtained from seed, it is best to procure them in a small state and grow them on to the size required. I must not omit to name one or two of the most useful plants of all for room decoration, namely, *Aspidistra lurida* and its variegated form, for no plant withstands the heat of a room better than these. They may be had in all sizes by dividing plants when small. Then there are the *Araucarias*, of which there are several species, all of which are raised from seed, or may be obtained in small plants for growing on, *Aralia Sieboldi*, so quickly grown from seed and some of the *Maples*, which make truly ornamental plants for grouping during the summer months. Few plants are more pleasing for room decoration than well-grown specimens in pots of *Acer Negundo variegatum*, as its foliage intermingles well with that of other plants of a bolder nature. From the above, ample material in the way of foliage may be found for the largest establishment. H. C. P.

**Slugs and Lapagerias.**—In many places, especially where conservatories are damp and shaded, the young succulent growths of *Lapagerias* fall a prey to slugs and snails. Their attacks

may be checked by the use of shallow troughs made of tin or zinc and fixed round the collar of the plants so as to meet and form a circle. These should then be filled with water, which slugs and snails will not face. Of course, the pests will occasionally find their way up the wall, and, descending the main stems of the plants, reach the young growths at the base, but as a rule where the tins are used very little damage is done.—J. C.

\* \* The best thing to ward off the attacks of slugs in the case of the *Lapageria* is to put a wide-mouthed lamp glass over the shoot as soon as the point can be seen coming through the ground.—Ed.

**Stenotaphrum glabrum.**—Among the plants suitable for forming living edges in the conservatory, of which a good selection is given on page 67, I should be inclined to add *Stenotaphrum glabrum* (the Australian Buffalo Grass), which with only a shallow soil to root in quickly forms a good edging to a stage, or in any similar position, and the shoots droop down for a considerable distance, thus doing away with any stiffness or formality. There is a variety in which the leaves are more or less striped with creamy white, but when growing freely it is often liable to revert to the type. Though generally known under the specific name of *glabrum*, according to the "Dictionary of Gardening" the correct name is *americanum*. It may be sometimes met with in Covent Garden Market, where, under the collective name of Grasses, a varied assortment of plants are occasionally brought together.—H. P.

### HOYA CARNOSA.

I HAVE two plants of *Hoya carnosa*, each 6 feet high, in 7-inch pots, in which they have been for three years. I want to pot them into 9-inch pots. Please tell me the best soil for them to flower in and the best time to repot them. They look very healthy now, but have never flowered yet.—G. FAWLER.

\* \* The best soil for this plant is peat with a small proportion only of yellow loam (about one-sixth). The peat should be full of fibre, so also should the loam, the finer or dusty particles in both instances being cast aside, for this plant does not thrive for any length of time in a close or retentive soil. To the peat and loam should be added some charcoal broken up to about the size of nuts, or in lieu thereof some clean broken potsherds would be a good substitute, the object in either case being to aid in keeping the soil porous. Silver sand also should be freely added. In potting take particular care to pot firmly, as by so doing the soil will remain much longer in a condition favourable to healthy root-action. For a time after potting some considerable care should be taken in the watering so as not to sour the new soil. At no time is *Hoya carnosa* a moisture-loving plant as compared with the average run of plants. Before it is watered it should be seen that the soil is fairly on the dry side. The extreme of drought should of course be avoided. The leaves should not at any time become soft or flaccid. Rather more water will be required when new growth is being made. The plants in question have not lost any time in respect to flowering; they may not possibly do so this year, even under the best of treatment. A sunny, warm position from the spring onwards will do much to encourage flowering. As young growth proceeds do not tie the shoots to the older wood, but allow them either to trail about or train them upwards on small strings. In potting be careful to use clean or new pots, also drain the pots liberally. Having two plants, I would advise, if it be practicable, that one be planted out, using the same soil as in potting, only in a considerably rougher state. Under this treatment the plant would, if favourably circumstanced, grow more freely, and in all probability flower sooner if not eventually so profusely. A large border would not be needed, but this and many other plants enjoy an extended root-run. *Hoya carnosa* is a very good plant for training on a wall; grown thus, if the wall be a

little damp, it will, Ivy-like, root into the wall. It has a tendency even to throw out these roots under pot culture. When the flower-trusses eventually appear, do not cut them, for the same trusses will go on flowering continuously for several years at least once and often twice the same season; thus it will be seen that cutting the trusses robs the plant of much of its beauty.—PLANTSMAN.

#### SOFT-WOODED WINTER-FLOWERING PLANTS.

THESE are now grown very largely, few places of any size being without one or more small span-roofed houses specially adapted to their culture. These being kept at a minimum of 50°, are very gay for some three or four months through the dullest time of the year. It is impossible to dwell on all the good things available for the purpose, but there are two or three worth noting at this particular time, as the season for their propagation for another winter is now fast approaching. Zonal Pelargoniums are among the best winter plants. They should be struck singly in small pots and shifted on twice, using at the final potting a stiff holding compost that will be conducive to firm, short-jointed growth, and potting firmly as for Strawberries. I have tried many varieties, but can find nothing better than such old favourites as Raspail, Guillion Mangilli, Constance and Queen of the Belgians. In fact, I look upon these in their respective colours as the best winter-flowering varieties in cultivation. If any correspondents have found anything better, perhaps they will kindly name the varieties. Raspail Improved hardly comes up to its name with me—a larger truss, but the growth is coarse and straggling. The summer quarters of these Pelargoniums and other plants intended for winter work are pits from which Potatoes have been cleared. They stand here on a bed of ashes close up to the glass, get plenty of air day and night, and are lightly shaded during very hot weather. Of the two Libonias, *L. penrhosiensis* is much the better; indeed, it is of its size about the best winter-flowering plant grown. It has been a dense mass of flower for the last two months. I find plants in 4-inch pots come in very handy for house decoration. They are used in connection with Ferns for grouping round large Palms, Dracaenas, &c. This Libonia is struck with the Pelargoniums and potted finally in a similar compost. A few of the old winter Begonias, as *fuchsoides*, *Carrieri* and *Knowsleyana*, can also be struck at the same time and a few plants of *Eupatorium riparium*. The branching flower-heads of the latter look well associated with scarlet and pink Pelargoniums. A batch of *Primula obconica*, if propagated by division, may find a place with the above-named plants, and with them through the winter months batches of *Freesias*, *Cyclamens* and *Bouvardias*. E. BURRELL.

**Iris reticulata for pots.**—This is a splendid bulb for pots. Last September I potted up some fifty bulbs into 4½-inch and 6-inch pots, placing them in the open. In December they were removed into a greenhouse, and now at the end of January they are in full bloom. If these bulbs are taken care of when out of bloom they will flower again next year.—J. C. F.

**Monochæstum sericeum multiflorum.**—In a warm greenhouse this is just now in flower, and a pretty little plant it is. It forms a freely branched bushy specimen, clothed with oblong-shaped leaves, while the flowers, which are each about a couple of inches in diameter, are of a very pleasing shade of purplish mauve. This *Monochæstum* is very free-flowering, and at this season of the year its bright-coloured blossoms are especially welcome. Much the same might be said of *M. Lemoinianum*, except that the flowers are of a deep rose tint. These *Monochætums* need a soil principally composed of sandy peat, and too much atmospheric moisture during the winter is very injurious to them. The *Monochætums* are nearly related to the *Pleromas* and *Lasiandras*, which

include among their number some most beautiful flowering plants for the greenhouse. *Lasiandra macrantha*, with its rich purple blossoms, is well known, while *Pleroma elegans*, at one time popular, is now rarely seen. It is difficult to maintain in a thriving state, but so beautiful as to be well worth a little extra care and attention. It forms a rather upright, but freely branching shrub, said to reach a height of 5 feet, though it will bloom when much smaller than this. The flowers, which are 2 inches across and of a rich bluish purple, are borne freely at the points of the shoots during the summer months. All the above are natives of the Andean region of South America.—T.

**Tuberous Begonias.**—Although these showy flowers grow with much freedom when they have got good hold of the soil, it not unfrequently happens that a percentage of the tubers fail to start when potted. When looking through Mrs. Harrison's garden at Weybridge in the early spring of last year I noticed that the whole stock of *Begonia* tubers was laid out on cocoa fibre fully exposed to the light. They were just pushing out new growths, and it appeared that they were starting very regularly and strongly. Mr. Glyde, the gardener there, told me that he makes it a rule to treat the tubers in this way. When they are potted at once they are liable, no matter how carefully the watering may have been done, to become too wet before new roots are formed, in which case the tubers will often rot away. If laid out in the manner above mentioned they can be frequently looked over and any signs of decay will be easily perceived and can be promptly dealt with.—J. C. B.

**The dropping of buds of Camellias.** My observation of this occurrence, as well as my past experience in cultivating the plant, have led me to believe that the main cause of *Camellias* dropping their buds is dryness at the roots, though I am aware that excessive moisture, especially if the soil be a sour one, and therefore unsuitable, is also a cause of buds dropping. It is in the months of January and February that so many failures of this kind are experienced. Not long since I was looking over the collection of a successful cultivator who has a number of finely grown plants coming into bloom, and he stated that in his opinion the prime cause of failure with amateurs is that they cannot or do not give the plants the attention as to air and watering they require at this season of the year, especially as to watering, as they become drier at the roots than they suppose, and when they water give just as much as the pot will hold, which is often not enough under the circumstances. The advice this grower gave is that the supply of water should be enough to keep the soil in the pots nicely damp, and no more, and to provide as far as possible an equable temperature.—R. D.

#### CROTONS IN SMALL POTS.

THE value of well-grown plants in 5-inch or 6-inch pots of the long, narrow-leaved and brilliantly coloured *Crotons* is well known. I have a whole house devoted to *Crotons* for house decoration, and grow them in two batches; the two-year-old plants after providing the cuttings for the season's batch are thrown away. The present is a good season for propagating. In taking off the cuttings use only well-formed shoots, as if small pieces are used with the foliage mostly gone it is impossible to secure well-furnished small plants. Sponge each cutting carefully in case there be any insects. Each cutting should be placed singly in a 2½-inch pot, plunging afterwards in cocoa-nut fibre refuse in the frame, where if kept close and fairly moist, also shaded from strong sun, roots will quickly form. Large well-developed tops are best notched and covered over with Moss so as to form roots before being detached. In these cases directly the Moss is fairly permeated with roots, the tops must be cut off and potted, afterwards plunging them in the frame to become established. After the cuttings are rooted stand them out in

the body of the house previous to repotting them.

The best results are obtained by repotting direct into 5½-inch pots, this being a useful size for decoration. The best soil is equal parts of loam, peat, and leaf soil, the loam being rough. Add also crushed charcoal, coarse sand, and a little artificial manure. Pot the plants firmly, standing each well apart from the other. Direct light being so essential for the plants' perfect development, it is an excellent plan, other room not being available, to suspend each plant under the glass roof, as in this position the most perfect colouring is developed. This may be carried out in quite large houses without interfering with the other occupants. Keep the roots regularly supplied with moisture, also syringe freely twice a day, using in each case tepid soft or rain water. Dryness at the roots will soon cause an attack of thrips or red spider. I do not care to water with liquid manure at any time, but if a stimulant is needed use some proven artificial manure. Well prepared soot water may also be used with advantage. A. YOUNG.

#### CHRYSANTHEMUMS.

##### GOOD JANUARY CHRYSANTHEMUMS.

VARIETIES in any section that flower freely during the first month of the year are especially valuable. It is an easy matter now-a-days with the abundance of Japanese varieties that there are to have plenty of bloom early in December as well as through the two previous months, but for January flowering the case is different, and any that are especially adapted for this purpose deserve to be universally known. With this object I have made a note of all that have come under my notice, especially during the current season. Fortunately, now-a-days we are not tied hard and fast to one or two colours—white and pale pink—as was the case a few years since. Much more of a choice is now available, as varieties with rich colouring as well as those of a deep yellow tone are not wanting. No doubt pure white-flowered sorts are the more useful. Undoubtedly the pride of place in this section of colour belongs to

*L. CANNING*, introduced by Craig in 1888. Early blooms exhibit a trace of ivory in the colour, but those from late buds are of the purest white. When first introduced I thought it would take a high position as an exhibition variety, but, unfortunately, it has a peculiar knack of going "blind" at a critical time—bud formation. This defect hampers its chance of ever becoming a show bloom. As we have abundance of white-flowered sorts for the exhibition table, the loss of this is not felt, but it is an assured gain as a useful variety for late use. Plants carrying from thirty to fifty well-developed, medium-sized blooms are valuable early in January for decoration apart from their value in supplying material for cutting. Being naturally dwarf in habit, it is better fitted for conservatory use.

*M. E. A. CARRIERE* is one of Délaux's 1889 introductions. As an exhibition flower it is sometimes seen in splendid condition, but cannot be depended upon. As a late-flowering variety it is really grand, especially when allowed to grow away uninterruptedly from the cutting stage, not interfering with its growth in the matter of topping of the shoots more than once, that being done when the plants are 5 inches high. By growing this sort afterwards upon the let-alone principle, removing what is known as the crown bud and running the growth on to produce terminal buds, abundance of flower is obtained with stems from 1 foot to 2 feet in length. After these main blooms are cut lots of smaller ones develop from the side shoots, and for wreath-making these are especially useful. When the earliest formed blooms begin to open they exhibit a distinct trace of creamy white, tinted with blush, but this

gradually passes away with age, leaving the fully expanded blossoms pure white. All smaller flowers afterwards are white from the commencement.

**LEON FRACHE** is very similar in its colour when the early blooms begin to expand, but with age they also change to pure white. In growth it is vigorous and quite erect, giving serviceable material for the filling of tall vases. The bark has a peculiar red tinge, contrasting strongly with its deep green leaves.

**PRINCESS MAY**, introduced by Agate in 1892, is another pure white-flowered variety that deserves attention. The growth is robust, the blooms large, with long thread-like petals, which seem to open exceedingly well at the end of December and early in January.

**MILLE THERESE REY** is not only one of the finest of the white-flowered ordinary November-blooming kinds we have, but it gives a quantity of late produce from side growths, which spring freely from the main stems after removing the points where the large blooms have been growing.

**PELICAN** is a much older variety, being one of a batch sent out by Bouchard in 1885. At all times the blooms are pure white, the incurving florets slit at the tips.

**EUGENE DAILLEDOUZE** arrived in the spring of last year from America, and is an acquisition to the late-flowering section. The medium sized florets incurve neatly while expanding, exhibiting traces of dull crimson on the reverse side. When fully expanded the petals recurve, showing a rich yellow surface.

**CHARLES BLICK** is an English raised seedling of medium size, which makes it all the more useful for decoration. The florets droop gracefully, the inner ones incurving towards the centre, the colour a shade of soft yellow.

**E. G. HILL** is an American raised Japanese incurved variety, more valuable as a late-flowering variety than aught else. The colour, golden yellow, is suffused on the reverse with carmine. By topping the plants twice in their early stages of growth, the plants run up fully 6 feet high if the cuttings are inserted early, as they should be.

**ROBERT OWEN** is perhaps the finest type of the incurved Japanese section we have, and as such it is valuable, but when the virtue of late flowering is combined it enhances the regard for any sort. The colour is yellow, suffused with bronze, quite pleasing and distinct.

**SOUVENIR DE MME. BULLIER** promises to become quite the best of richly coloured late varieties. The surface colour is best described as a rich port wine, with just a tinge of plum colour suffusion; the reverse is dull red. The narrow flat florets are blunt at the tip. Growers should make a note of this for late flowering.

**VIOLET ROSE**, an incurved Japanese, distinctly rose in colour, is useful where variety is required. Full, solid blooms are produced quite late.

**EDA PRASS**, although regarded as a really good November-flowering kind of the incurved Japanese type, is also useful for giving flowers in January. The colour, light salmon-pink, fades to bluish. All of the above belong to the Japanese section.

**GUERNSEY SUNSET**, a single-flowered variety, is extremely useful, giving a quantity of useful flowers in the early part of January. The florets are yellow with a bronzy suffusion.

**HENRY PERKINS** was first sent out as a Chinese or incurved variety, but it has since been relegated to the incurved section of Japanese, to which it rightly belongs. As a late-flowering sort it is useful to those who care for these dull-coloured types. In colour it is bronze, shaded with rosy chocolate. Neatly incurved blooms can be had quite as late as the third week in January.

E. MOLYNEUX.

**Chrysanthemum W. H. Lincoln.**—This Chrysanthemum is without doubt—as “J. C. B.” (p. 76) and Mr. J. C. Tallack (p. 58) say—exceedingly valuable for late bloom, though I should not have thought that it was necessary to disbud

the variety to the extent advocated by the latter writer, if at all. I have in my mind a plant that was produced from an old stool which was put in the open ground in February, 1894. This was left absolutely untouched from the time it was planted out till it was taken up and potted in an 11½-inch pot in October, when it was brought into a late Peachhouse. Nine stems rose from the soil, which stems divided into eighteen, and then again into forty-eight, producing that number of flowers, which averaged 3½ inches in diameter. The blooms were cut on December 24 and remained fresh till after January 1. A few days before the flowers were cut a nurseryman offered 4s. for the plant as it stood. If a few hundred such plants could be potted and housed in the autumn and succeeded equally well, this Chrysanthemum should prove a veritable gold mine to the market grower. Of course the instance I refer to was but a solitary one, and I am aware that too much reliance should not be placed on what might prove merely one of those exceptions that prove a rule. Still the fact remains that in one case this variety has done its own stopping and disbudding very satisfactorily. The centre bloom on each shoot seemed to monopolise the sap to such an extent, that the others either refused to swell at all, or developed into small, mis-shapen blooms, showing but a dozen or so yellow petals. The total height of the plant did not exceed 2 feet 3 inches from the pots.—S. W. F.

**Chrysanthemums Boule de Neige and Ethel.**—In the notes on Chrysanthemums at page 58, Mr. J. C. Tallack, in speaking of Boule de Neige, says, “the flowers are pure white, and remind me very forcibly of those of Ethel, which it greatly resembles.” &c. Does not this sound somewhat strange, seeing that Boule de Neige belongs to the hybrid pompon class, while Ethel most certainly belongs to the Japanese section. Moreover, the former has short, blunt, and rounded petals, while the latter has much longer petals distinctly and acutely pointed, and in these respects the kinds named are perhaps two of the most distinct. In habit, generally, they are equally dissimilar, the one dwarf and bushy, the other tall and erect. Apart from both kinds having white flowers, I only know one point—and that a bad one—in which both are alike, namely, that of showing a black centre much too frequently. But there is really very little need to grow either of these kinds in the future, while we have others vastly superior in their flowers and equally late in flowering. I refer specially to Lady Lawrence and L. Canning. Like Mr. Tallack, I had a doubt about the freedom of the latter when it began to expand, but now I have little fear that with stronger cuttings another season it will be all right. The season of 1894 was not remarkable for sun heat, and I am of opinion that the very late kinds of Chrysanthemums especially suffered in consequence.—E. J.

**Chrysanthemum catalogue.**—In the last-issued supplement to the centenary edition of the catalogue of the National Chrysanthemum Society there are some errors, which, when the catalogue is entirely revised, as hoped for in the preface to the supplement in question, will need correction. In the first place I note the date of the incurved variety Lucy Kendall is given as 1893, and John Shrimpton and William Seward as 1892. Now, as a matter of fact, the three varieties were first exhibited in the autumn of 1892, and were all distributed in the spring of 1893, so that whether the date be taken from the time of their receiving a certificate, or when they are first sent out, there is a mistake somewhere. Beauty of Castlewood (Spaulding), 1892, is also an error, as it was catalogued by Mr. Cannell in 1890, and received a first-class certificate from the National Chrysanthemum Society in the autumn of that year. Mr. Cannell is credited with the Japanese incurved William Tricker, but that is of American origin, and so described in his catalogue. Of the large Anemones, Cincinnati (Cannell), 1886, was one of many others sent to this country from America in 1885. This was, I think, the first large consignment of new Chrysanthemums from

across the Atlantic. Besides the variety Cincinnati, we received from America nearly sixty varieties, some of which were popular for a time, but have since given way to newer forms. Among the most notable of the 1885 varieties were—of Japanese—Bicolor, Fimbriatum, Gloriosum, Hon. John Welsh, Mrs. William Mencke, Snowstorm, Syringa, Gorgeous, Moonlight, Mrs. C. W. Wheeler, and Samuel Henshaw. Mrs. James R. Pitcher, valuable as an early flowering variety, also came at the same time. There were also several single-flowered forms, one of which—Mrs. A. le Mout—has been within the last year or two more than once noted in THE GARDEN. The Anemone varieties consisted of four, there being, besides Cincinnati, Agnes Hamilton, Merrimac, and Wyoming.—T.

**Chrysanthemum Sœur Melanie.**—This pompon variety was introduced by Lebois as far back as 1869, and no better kind really exists when we consider the freedom with which its blossoms are produced and their purity. I know of no Chrysanthemum that makes a better pot plant than this, and its buds open simultaneously. For cutting it is a decided gain to have all of its flowers fully developed at the same moment. There is not the waste then as with some sorts that just open the centre flower of the bunch, the remainder staying so long dormant as to spoil many unopened blossoms if cut with a long stalk. It is a good kind to grow as an edging to groups of Chrysanthemums in pots in public gardens, where oftentimes the leafless stems of the front row plants are an eyesore. The plant retains its foliage until the flowers are cut or faded. As an out-of-door variety it is quite one of the best, flowering not only profusely, but quite early, thus escaping to a great extent the early winter frosts which do so much toward making this aspect of Chrysanthemum culture a failure. Plants smothered with flowers can be had either 2 feet or 4 feet high. The finest batch of the latter class I ever saw was last November in the Pilgrim Nurseries of Messrs. R. B. Laird, Edinburgh. Fully two hundred plants were blooming in great profusion, the flowers being found useful for cutting.—E. M.

#### CHRYSANTHEMUMS WITH A SINGLE STEM.

I HAVE some 300 Japanese and incurved Chrysanthemums, the cuttings having been struck last December. I wish to grow them on with one single stem until the natural break, say in May, June, or even July, and thus carry on three shoots only. The only fear I have is that they will not show a bud in May, June, or July, and thus will continue to have only the single stem. If this is so, the said stems will grow too high and I shall only have one flower on each plant. I have for some years cut them all down early in May and allowed three stems to grow, and they have averaged in height from 3 feet to 5 feet. The Japanese blooms have been grand, but the incurved have always been wide and loose. I desire them all to flower in November. I have good convenience to house them all.—E. JOHNSON.

\*\* You need have no fear that your plants raised from cuttings inserted as early as the middle of December will not show the first bud early enough to provide three shoots to each. Many of the varieties will make their first natural break in April, others later. We often hear complaints about plants not making the natural breaks in their growth sufficiently early to admit of their forming flower-buds at the right moment. In searching for the cause it is generally found that the cuttings were not taken until the middle of February. Late propagation does not admit of sufficient time for the various stages of growth being made at the right period. It is not possible to obtain first-class blooms from plants that are not thoroughly matured. Nothing but a long season of steady uninterrupted growth will mature the plants. Especially is the want of maturity of the wood felt in the incurved section, where solidity of petal and fulness in the

centre are more important than in the case of Japanese blooms. Plants of the latter section give really good results when treated on the cutting-down principle for decoration, but seldom can the blooms be compared to those produced by plants growing in a more natural manner. When the decoration of the conservatory or dwelling house is what the plants are most needed for, then the lack of quality in all its essential points is not so noticeable as in the case of exhibition blooms.—E. MOLYNEUX.

#### GENEVAN PLANT PROTECTION SOCIETY.

I MUST ask to be allowed to send a few more words to you on behalf of my old friend, M. Correvon. I have just now received a long letter from him, and he puts the whole matter in the clearest possible light. He simply says about *Eritrichium nanum*, "I defy Mr. Leonard to prove his assertion." The word of an honest man and that about some practice of his own ought certainly to be enough. But there are two or three very important points in the long communication I have received which possibly may be quite new to Mr. Leonard, and which may lead him to think twice before he accuses another person so roundly.

1. According to M. Correvon, he has oversight of two separate gardens which are managed in different ways, whose objects and surroundings are quite different, and where no comparison of one with the other should be made. The first may be said to exist on public and scientific grounds. The second is a private adventure, and where a regular business is carried on I can see no reason in the world why the same man should not be at the helm in both cases. Nor do I suppose that anyone else would object to it, and this applies also to the society for protecting alpine plants. But the bearing of all this on the controversy in question is very great indeed. M. Correvon says: "We have founded in the Alps of Valais, the garden of the Linnæa, for which the Swiss Government gives me allocation. That garden does not trade at all. It is a conservatory of the alpine Swiss flora, and we took it, as it is situated 1700 mètres in the Alps, and it is allowed to us because the plants succeed all very good there—living plants, &c." What he means is clearly this: It is not murder to take up a large plant of *Eritrichium nanum* and transfer it from one alpine height to another, because under conditions of this sort the plant will not be wasted, but will prosper abundantly; secondly, it is not done for any purpose of private gain; and thirdly, it is a matter which is recognised and allowed by the Government under which he lives. The mountains are not denuded in the least. M. Correvon only tries to focus in one spot a few of the treasures with which they are clothed, and he acts quite openly about the matter, having obtained the *imprimatur* of the authorities under whom he is living.

But (2) with regard to articles of commerce he denies explicitly that any rare and prohibited plants are ever torn by him from the mountains at all. In the first place, he believes that such a proceeding would have no chance of succeeding—the plants would be sure to die—and in the second he is under engagement to take a very different course; and he challenges anyone to adduce the smallest semblance of proof that he has not been true to his colours.

3. It should be noted that a list of protected plants is always given by the society which M. Correvon represents, and that nothing else is regarded. His words are these: "We would not take the engagement of not rooting up common plants." To attack him for touching common plants is very much the same thing as though fault were to be found here with the removal of a Primrose or Daisy, while the few remaining haunts in this country of *Gentiana verna* or *Cypripedium Calceolus* are jealously guarded.

4. He seems very much to regret that quite recently in last year the Swiss Alpine Club took

the decision, as he calls it, of sending an appeal to each Swiss cantonal government to ask them to make laws defendant *expressément* the uprooting of any plants at all, and he regrets that it passed. The minority, of which he was a leading member, considered that a law of such a drastic and sweeping sort as that would defeat its own purpose in the end, and that some rare and very interesting plants would suffer from the measure which was meant to preserve them. But so long as things stand as they are, a perfectly new condition has been introduced into all this affair.

It is difficult to believe that Mr. T. Smith, of Newry, was serious in what he said to you on Saturday last. By this morning's post a letter came to me from one of the highest authorities of the day in matters of this sort. One sentence in it ran thus: "Speaking generally, I agree with you that seedlings properly managed (*i.e.*, from thinly-sown seed and pricked off at the best time) give better results than disrooted plants from their native habitats," and M. Correvon very pertinently says in his letter to me, "If Mr. Smith can find in the Alps any young plant of *Azalea procumbens* to be able to be planted in a pot, I will be astonished." Mr. Smith seems to me to be conscious of the weakness of his case when he says about imported plants, "Of course, they require some care to be established," and I regard him as throwing it all away when I read such a sentence as that. Not only do many imported plants require "some care," but they very often cannot be established at all, when seedlings answer quite well.—H. EWBANK, *St. John's Vicarage, Ryth, Isle of Wight.*

\* \* \* Our readers are tired of this discussion; so are we. M. Correvon sends us a few pages in French as an answer to Mr. Leonard, but does not in them mention THE GARDEN as the journal in which the discussion appeared, and also omits to state that himself and his friends had the same opportunities of giving their views as Mr. Leonard had. We can publish no more notes on this matter.—W. R.

#### NOTES OF THE WEEK.

**Cattleya Trianae.**—The varieties of *Cattleya Trianae* are already making a fine show in collections, as *C. Percivaliana* is going out. Large importations of the former species are now being sent over and sold. Some truly fine specimens are now to be obtained from the dealers in these plants, and the probability of good varieties being amongst them makes their flowering very interesting to amateurs.—J. D.

**Skimmia oblata Foremani.**—How seldom do we see this shrub made use of for winter decoration. In sandy soil, where it grows and berries freely, it is a simple matter to pot up the plants as required in the autumn. This variety appears to be a slight advance upon the type, the berries being somewhat larger and the colour, if anything, richer. At the late Edinburgh Chrysanthemum show a group of thickly berried plants of this *Skimmia* was very attractive.—E. M.

**Colour in Ivies.**—I planted the north side of the house here with Ivies (the sun never catches it, through hills east and west shutting all chance out). The leaves of the Irish Ivy assume that beautiful bronze we never get in a south aspect, and a golden-leaved variety improves in colour year after year. Honeysuckles intermixed flower most profusely, and *Ampelopsis Hoggi* growing amongst these shows a marvellous bit of colour in autumn.—GEORGE BOLAS, *Hopton Hall, Derby.*

**Pear Glou Morceau.**—With me on a strong soil this Pear (figured in last issue) is not a success, although grown as a cordon against a wall. In my case the roots are kept as near the surface as possible. The trees make good growth, but the fruit does not ripen sufficiently well to encourage me to plant it freely. Bush trees growing in the open were a complete failure, and were cut down to make room for something more profitable. This

is a grand Pear on warmer soils, but on heavy soil it is not so.—E. M.

**Puschkinia scilloides.**—It would seem as if the most essential thing for this little gem of spring bulbs is a place where there are no slugs. They are certainly extremely fond of it. I know one who gave up trying to grow it because deformed and mutilated flowers were all that ever appeared. A short time back before the snow came I went to examine a border of spring bulbs to see if any were peeping through, and found that the points of this bulb were above the surface, and scarcely one had escaped injury from slugs.—A. H.

**Dendrobium luteolum.**—The pale yellow flowers of this species are not usually very attractive, but a large well-flowered plant in Messrs. Veitch's nursery showed its value for decoration. These distinct yellow-tinted forms are useful for hybridising. No one could have supposed that such beautiful garden varieties as *D. Ainsworthii*, *D. Leechianum*, *D. splendidissimum*, *D. Schneidrianum*, &c., could have been produced from such a poor grower and rather mediocre-looking species as *D. aureum* (*syn.*, *heterocarpum*).—J. D.

**Christmas Roses.**—I am disposed to think that many failures with these arise from starting with large plants at first, particularly if they have been, as I have frequently seen them, washed clear of all soil. It is difficult to get the mould back into all the interstices when planting, and decay sets in as a matter of course. With small plants it is otherwise. The roots can be spread out so that all are in contact with the soil, and the plants soon become established. Given small plants and a well-drained loam, I think fewer failures would occur.—T. J. WEAVER, *Crouch End.*

**Manettia bicolor.**—I was much interested in the note on *Manettia bicolor* in a recent issue of THE GARDEN. Its peculiar tubular flowers, of a waxy consistency and of a beautiful scarlet shade with yellow tips, on stalks some 3 inches in length, render it invaluable for button-holes. It can be grown either trained balloon fashion in pots of any size, from 4½ inches upwards, or on wires under glass. Ordinary greenhouse treatment will suffice. Some plants I lately saw have been in bloom since the end of May until the present time, and look as if they would continue flowering for some time yet.—P. G. BARTRUM, *Tooting.*

**Tree Pæonies in pots.**—A plant of that lovely Tree Pæony *Reine Elizabeth*, growing in a pot and already bearing several fine flowers, suggests one certain way of fully enjoying the great beauty of this and other kinds. As yet none of them are common or very popular in gardens, which is surprising considering the size and gorgeous beauty of their flowers. They are slow-growing things, but, all the same, bloom well enough in a young state, and under glass retain their fine form and purity of colour unmarred by any inclemency of weather, such as too often prevails at the time of their flowering in the open air.—A. H.

**Saccolabium Harrisonianum.**—This beautiful white, deliciously-fragrant form of *S. violaceum* is now in flower. I bought plants of it many years ago for *S. giganteum*, from which it does not differ much. They are both sweetly scented. *S. giganteum* is much larger in all its parts, and the flowers of *giganteum* are purplish spotted on a white ground. *S. violaceum* is quite common in the Philippine Islands, while *S. giganteum* is a Burmese species. The plant is found in great profusion and luxuriance on trees in a deciduous jungle, exposed to the rays of a tropical sun, and in most cases with its leaves scorched. We do not want to see the leaves scorched in our collections; therefore the plants are carefully shaded. The plants succeed admirably in the warmest house if given clear drainage with an inch in depth of freshly-gathered Sphagnum Moss mixed with the drainage.—J. D.

**Chinese Primulas.**—Messrs. Stuart and Co., Covent Garden, send us a collection of their *Primula* blooms from plants that have been grown at Nice.

The blooms came to us as fresh as if newly picked, the colours being well preserved in every case. The flowers, by no means coarse, represent fully the many varieties now in cultivation. Among the sorts sent were Chiswick Red, the colour very rich; rubro-violacea, remarkable for the violet shade; alba magnifica, a fine flower of good substance; Fern leaved white, and many others. One in particular named Stuart's New Crimson struck us as being remarkably fine. The flowers, of medium size, were striking, the colour intense crimson, certainly the brightest we have yet seen. Evidently the finest culture had been bestowed on the plants, showing that a bright and sunny clime is needed to bring out to the full the many beautiful hues that are to be found in the Chinese Primula of to-day.

**Pilumna fragrans.**—The flower to hand from A. Brooker arrived in a very bad condition, but I should presume it to be of this plant. It is sometimes known as *Trichopilia fragrans*. This plant has been known for a considerable number of years, and has been imported by various firms in large quantities from New Grenada, and as it will thrive well in a cool temperature, it is very suitable for amateurs. It should be potted in fibrous peat and Sphagnum Moss with a few nodules of charcoal, and as it will require plenty of water during the growing season, the drainage must be good. Raise the plants well up above the rim of the pot, and whilst at rest the supply of moisture must be greatly reduced. The flowers of *Pilumna fragrans* are very sweetly scented, and borne about three or four together upon radical peduncles. The sepals and petals are about equal and slightly wavy, white, mostly tinged with green; the large lip white, stained with orange-yellow at the base.—G.

**Lælia anceps Sanderiana.**—This is one of the most beautiful of the white-petalled forms of *L. anceps*. I saw it very beautifully in flower in Messrs. Veitch's nursery the other day, and it was equally fine in our own collection. It differs but little from the celebrated variety *Dawsoni*, except that it has less colour on the lip, and the petals and sepals of *Sanderiana* are longer in proportion to their width. The great value of *L. anceps* and its varieties consists in their easy culture, and in the fact that they are always to be depended upon and keep up their constitutional vigour for any length of time. The accounts we have received from some of the collectors of the climatal conditions of their native country conclusively prove how very hardy they must be. I once marvelled to see a man turn the hose on to a houseful of Mexican *Lælia*s in Messrs. Baekhouse's nursery at York on the afternoon of a sunshiny day with no shade for the plants. It was marvellous to see how well they looked, but the treatment was very similar to the natural conditions which obtain in their native country.—J. DOUGLAS.

**Daffodils in pots.**—Every lover of Daffodils likes to have them for as long a season as possible, and since they are so amenable to pot culture and lose none of their charming grace and beauty when grown in this way, it is surprising one does not see them in pots more often. Hard forcing they do not like, but they can be brought on gradually to flower some weeks in advance of those outside, and most welcome they are. I have just called upon a neighbour whose greenhouse is quite gay with them, making a pretty display at small cost of labour and fuel, for he has done little more than keep the frost out. Among the kinds in bloom I noted pallidus præcox, Countess of Annesley, Sir Watkin, Duchesse de Brabant, ornatus, and Leeds, white and yellow types. Many more kinds will be open in a few days. There is not much trouble and little outlay involved in the pot culture of these bulbs. A few kinds, notably Sir Watkin, continue to flower freely, although kept in pots two or three years in succession, but there are exceptions, and the general rule for safe guidance should be to give the bulbs one year in the open ground and one year in pots. With a piece of reserve ground for the purpose this is a simple and easy matter.

They amply repay the trouble, and are doubly welcome in a season like this, for the snow lies deep and the spring flowers will be later in consequence.—A. H.

**Eranthemum pulchellum.**—There is no flower that provides such a striking shade of blue in the stove at this season of the year as the above. Blue is a scarce colour in winter, and the full rich tone—almost gentian-blue—of the blooms always attracts attention. The plant, which is a native of the East Indies, is easily propagated. Cuttings of the young growth taken in the spring root very quickly in sandy soil if kept close, and by the winter, with a little judicious stopping, make good plants bearing many panicles of bloom. Autumn-struck cuttings in small pots, if well treated, produce handsome flower-spikes and look well associated with the giant strain of white Cyclamen, which can be flowered well in heat during February. *Eranthemums* are sometimes grown in frames during the summer, and where constant attention cannot be given to keeping the atmosphere charged with moisture this is doubtless a good plan. Hot-house treatment when rationally carried out is, however, the most conducive to success. Plenty of water, both in syringing and in damping floors and stages, should be used, or red spider will make its appearance. Care should be taken to ventilate but sparingly, as this *Eranthemum* is impatient of draughts and does best in a somewhat close atmosphere. Liquid manure may be used with good results, especially as regards the older batch of plants. Unfortunately, the flowers drop as soon as cut, and are therefore useless for decoration.—S. W. F.

**Oncidium tigrinum and O. splendidum.**—I saw the other day the two *Orechids* above named beautifully in flower in Messrs. Veitch's nursery at Chelsea. The one species cannot very well be mistaken for the other. There is a very good coloured plate of *O. tigrinum* in the *Magazine of Botany*, vol. xiv., 97, under the name of *O. Barkeri*. It was so named by Dr. Lindley in 1841. The true *Oncidium splendidum* is figured in the *Botanical Magazine*, tab. 5878, as *O. tigrinum splendidum*. They seem to be as species quite distinct from each other. I find them not so easy to keep in a good healthy condition, but there is no doubt that if we could hit the right treatment they require at different seasons of the year we would be quite successful with them. They certainly do best with a Cattleya house temperature, but most of the Mexican *Orechids* seem to require a drier, rather more airy position than the South American *Orechids* requiring the same temperature. They also want a more decided season of rest, while they can do with a good supply of water until the bulbs are well developed. I have grown *O. Barkeri* of Lindley for many years, and can look with pleasure on the long branching spikes for some four or five years after they have been imported, but it is rather annoying to find them decrease in size after a time and become quite small in comparison to what they used to be. *Orechid* fanciers who value this beautiful *Oncidium* for its sweetness and beauty, and all the more at this dull season of the year, must purchase a few plants periodically.—J. DOUGLAS.

**The weather in West Herts.**—The present frost has now (Wednesday) lasted sixteen days, during which period the exposed thermometer has on no night registered less than 12° of frost, and on nine of these nights it showed over 22° of frost. The coldest day as yet was the 6th, when the temperature in shade never exceeded 25°. During the preceding night the thermometer in the screen, and 4 feet above the ground, showed 22° of frost, while that on the surface of the snow fell 1° below zero, thus indicating 33° of frost. Both of these readings are the lowest recorded here since January 8, 1886, when they were in each case 3° colder. In the screen the temperature on Tuesday night remained at nearly its lowest point from 3 a.m. to 8 p.m., or for five hours. Owing to the covering of snow the soil temperatures

have not fallen so low as they otherwise would have done. Up to the present time the frost has, however, penetrated the ground to the depth of a foot. For more than a week the direction of the wind has been some point between north and east. On the 5th the sun shone brightly for very nearly seven hours.—E. M., *Berkhamsted*.

**The late Mr. William Thomson, of Clovenfords.**—During the last thirty years it was my privilege on many occasions to come into contact with the above-named gentleman, whose loss the horticultural world is now deploring. In many respects our departed friend occupied the "pride of place" as a gardener, and on this ground I think that some effort should be made to perpetuate his memory. Another (and perhaps a more important) reason why I think this suggestion should be carried out is in consequence of those higher qualities which our departed friend possessed in an eminent degree. No one could be in the company of William Thomson very long without coming to the conclusion that he was a man of integrity and uprightness. There was a tone, an atmosphere, if I may use the figure, about him which one inhaled, and so became the better and stronger. On several occasions I was struck with his conduct to those under him. He beheld them as fellow-creatures, and knew that they had as much right to happiness as himself. Disdainful looks, proud, snappish, severe speeches, which some can make use of upon every supposed offence, were seldom seen or heard from him. From the best of principles, therefore, his servants were bound to serve him—the principle of love. I sincerely trust that someone more capable than myself will take this matter up; if so I will do all in my power to assist.—BRUCE FINDLAY, *Manchester*.

I WENT to stay at a very grand and beautiful place in the country where the grounds are said to be laid out with consummate taste. For the first three or four days I was enchanted. It seemed so much better than Nature, that I began to wish the earth had been laid out according to the latest principles of improvement. In three days' time I was tired to death; a thistle, a heap of dead bushes, anything that wore the appearance of accident and want of intention was quite a relief. I used to escape from the made grounds and walk upon the adjacent goose common, where the cart ruts, gravel pits, bumps, coarse ungentlemanlike Grass, and all the varieties produced by neglect were a thousand times more gratifying.—SYDNEY SMITH.

**Royal Horticultural Society.**—The next meeting of the R.H.S. will take place in the Drill Hall, James Street, Westminster, on February 12. The various committees will assemble at noon as usual, and at 3 o'clock the annual general meeting of the society will be held in the offices, 117, Victoria Street.

**Keeping off rabbits.**—Would you kindly inform me what mixture is the best to paint young trees with in a plantation to keep rabbits from biting them?—A. P. C.

\* \* The best way is to wire the plantation and endeavour to keep down the rabbits. It is extremely difficult and unwise to paint every tree in a large plantation.—ED.

**Thomson.**—On February 3, Aliek, the only son of W. P. Thomson, of THE GARDEN, died in his sixth year.

**Names of plants.**—*J. B.*—*Myrsiphyllum asparagoides*.—*Fern.*—*Nephrolepis exaltata*.—*W. Eastwood.*—*Odontoglossum crispum*, a fine form, and we should like to see it again when the plant has become established.—*R. E. Bayne.*—Ordinary form of *Dendrobium Wardianum*.

**The Wild Garden:** or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers. Fourth edition, with wood engravings from drawings by Alfred Parsons, revised and enlarged. Lemay & Co., London. Price 12s.; well bound in half morocco, 18s. Through all booksellers.

No. 1213. SATURDAY, February 16, 1895. Vol. XLVII

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## FLOWER GARDEN.

### GLADIOLI IN SCOTLAND.

I HAVE always thought that the somewhat arid climate on the east side of Scotland is inimical to the Gladiolus. In Ireland it grows splendidly and succeeds year after year; and in the same way in Ayrshire, where in a few places it is made a speciality of, it does extra well and the varieties increase according to their kind. I have still varieties that were originally purchased twenty years ago, but the seasons including and following 1877 cleared out most kinds. The plants, as a matter of fact, had an insufficient space of time—considering the nature of the weather of these years—in which to make and ripen corms. Ever since then I have started the corms into growth before planting, and in this way have secured for them a better growing season. Last year has proved one of the worst, as numbers had not finished growing when frost in October cut them down. It is doubtful whether the Gladiolus degenerates. No doubt some kinds, from an inherent weakness of constitution, invariably fail to make stock, and they slip, as it were, through one's fingers. Mabel is one of them, so is Fleur de Lys, as well as Mme. Desportes and Michael Angelo. But there are many beautiful sorts that go on increasing year after year, so that it becomes a matter very much of selection in order to keep up a garden stock. Writing of the degeneration of the individual bulb, "Delta" makes an unaccountable slip. He refers to it as if decrease in size followed year after year in the same bulb until it ultimately disappears; whereas a new bulb, or, more correctly, a new corm, annually replaces the old one, and carries forward the individuality of the plant to another year. That in the case of certain varieties this kind of degeneration does occur there is no reason to doubt, but outside of these are numbers to which no such term is applicable. The comparative size of the corms, it may be said, depends largely on treatment, but influenced by weather in some degree. If there is abundant root-growth in conjunction with strong, healthy foliage, the corms are certain to be large. However, I have not found that large corms are any better, if so good, as those of medium size. They vary, in fact, from year to year, and if a medium or even a smallish corm is well ripened, quite as good a spike will result, though no doubt the number of spikes will be fewer in the aggregate where the collection embraces a large number of plants. As Gladioli are grown here mainly for cutting, and as it happens not infrequently that the plants are cut close to the ground in order that very long spikes with foliage may be had, it follows that first-class corms cannot be expected. I have already noted how well they do on the west coast, but even here, when the plants receive every attention, they succeed well. I some years ago purchased for an amateur a selection of good kinds, to which he annually added a few novelties. In a few years after commencing their culture he was obliged to dispose of surplus stock, and did so for years until he left this district. They were particularly well done, too, being started

under glass, and after planting out protected from cold and every care taken to preserve the foliage. One of the workmen on the estate here who started with a very few also grows them well. Last year he took at least four prizes, and I know he purchases none, so that the spikes he exhibits are *bona fide* home-grown. Good spikes of Gladioli are so valuable when cut for furnishing vases, that it is worth while to study their requirements in order to discover what treatment suits them in the particular district in which one may live. In this way I tried an old practice of starting the roots previous to setting them in the soil, and found it distinctly advantageous. The labour is not much, for the corms are set as closely as they can be placed together in ordinary cutting boxes with a shallow layer of leaf-soil under them. From this in May they are planted into the ground and much closer in the lines than generally advised; 4 inches apart is the widest I allow. The beds are raised. In dry weather they must have water, and manure of some soluble sort is imperatively necessary. As a rule, the plants ripen well, and it is very much better to lift them after growth has finished and let them lie on the open border to ripen than it is to dry them off in vineries or other cool houses. I have tried both methods, and the former is undoubtedly the best, as it is indeed the one I pursue with many other plants. I may add that I cut as early in the year as growers in the south of England.

In order to succeed year after year, one requires to be pretty careful in selecting sorts. Happily, there is a good number of really fine kinds that do well, and now so cheap that they can be bought by the dozen or hundred without running up a big bill. I name some below which are French, as I have but slight knowledge of English sorts. All are distinct, though placed in sections according to colour. White or nearly: Amalthée, Amitié Beatrix, Diamant, Enchantresse, and Shakespeare. Blue, opal, rose of many shades: Bicolor, Dalila, Fra Diavolo, M. A. Brougniart, Panama, Pasteur, Phoenix, Sceptre de Flore, Sultane, and Tere-sita. Red: Flamboyant, Grand Rouge, Dr. Bailly, Le Vésuve, Meyerbeer. Lilac shades: Baroness B. Coutts, Crépuscule, l'Unique Violet. Orange-red: Celimene; and reddish purple: Horace Vernet. A few sorts, such as Passe Rose among the new and Mabel among the old kinds are very beautiful, but they are expensive.

R. P. BROTHERSTON.

Tynningham.

**Crucianella stylosa coccinea.**—For quickly covering large patches on the rockery this is one of the most useful among hardy plants. Of dwarf trailing habit, growing only some 6 inches high, and spreading out into neat, compact tufts, it is especially helpful in furnishing large rockeries or for clothing sloping banks where few plants thrive. In spring when in flower the tufts are simply studded with the globular heads of crimson flowers, which continue in profusion several weeks. It is also well suited for the rockery border, where it should be allowed to ramble among the stones; or planted as an informal edging it may be used with good results in many ways, particularly where Grass does not do well. For example, in many small gardens small slopes occur on which we see Aubrietias and Arabis. In such places the above plant may be used with good effect, especially so if alternately planted with the white Arabis. The Crucianella is easily increased by cuttings of the young shoots in spring, almost every bit rooting in a few days.

—E. J.

**Christmas Roses.**—While *Helleborus niger* and *maximus* flourish in this garden where the

soil is inclined to be heavy, retentive, and consequently cold during the winter and spring, three miles from here—Shedfield Lodge—where the soil is sandy, Mr. Chequer cannot get them to succeed at all. He has tried them in the open ground and also in very large tubs of prepared compost, with similar results. I am a great advocate of the "let-alone" principle in Christmas Rose culture when once the plants have become established in any favourable position. My plants have occupied their present position in a border facing east for the last twelve years, and I have never once since missed a full crop of flowers, commencing at Christmas and continuing until the end of February. The roots are so arranged that an ordinary two-light garden frame can be placed over them at the end of October. From that time until the following spring the plants do not receive any water artificially, but while they are making their growth they receive copious supplies of water and occasional doses of weak liquid manure. I notice where any part of a plant does not grow so freely as others, a much thinner crop of flowers is obtained from that part. Directly the flowering period is past all seed-pods are removed, the surface soil is pricked up gently, and a dressing of freshly-chopped loam is added an inch or so thick, to be followed by a good mulching of half-decayed horse manure, which is allowed to decay and mix with the soil, washing the juices of the manure down to the roots.—E. M., Swanmore Park, Bishop's Waltham.

### EXHIBITION OF LILIES.

I RECENTLY noted in a contemporary that the Royal Botanic Society of Manchester have resolved to hold a great exhibition of Lilies in the gardens at Old Trafford, to open on the first Monday in August next. Now, beautiful as the different members of the genus are, they certainly do not lend themselves to a special exhibition, one great reason being the fact that their flowering season is spread over a lengthened period, beginning in the early part of the year with forced specimens of *Lilium Harrisii* and *L. candidum*, and out of doors about the end of May with *L. pyrenaicum*, while the Neighberry Lily (*L. neighberrense*) is the last of all the Lilies to bloom. Where a considerable number of this is grown some will often flower in September, while others will not bloom till nearly Christmas. In the early part of August the choice will certainly be very limited, for most members of the genus are over by that time. The whole of the erect cup-shaped Lilies, of which the best known are *L. bulbiferum*, *L. umbellatum* or *davuricum*, *L. elegans* (represented in our gardens by numerous varieties, differing from each other more widely than any other Lily), and the old Orange Lily (*L. croceum*), are all past, unless it be a flower or two of *L. elegans venustum* or *armenicum*; and of the large Martagon group, *L. superbum* is the latest. This is an August-flowering Lily, and a few flowers may be sometimes had of that most graceful species, *L. Leichtlini*, the ground colour of which is pale yellow, dotted with brownish red. This brings us to Mr. Baker's Archelirion, or open-flowered Lilies, to which most of those that bloom in August belong. *L. auratum* is one of this group, and although this Lily cannot be forced or retarded as some of them can, yet many may be had in bloom by the early part of August. The typical *auratum* is by no means the only form, for we have the well-marked varieties *platyphyllum*, *rubro-vittatum*, and *virginale*. Of these *platyphyllum* is altogether more vigorous than the typical kind; the leaves are also broader, and the flowers, which are very thick and massive, are more saucer-shaped. As a rule, the blooms of this do not show the same variation in the marking as those of the type. A spotless white flower is *virginale*, or *Wittei*, as it is often called. The only tinting is a yellowish band down the centre of each petal. This is in constitution the most delicate of all the *auratums*. The marking of *rubro-vittatum* is very different from that of the last, each petal having a broad stripe of

crimson down the centre. This is also known by the varietal name of *eruentum*. If these Lilies are grown in pots for flowering early in August, care must be taken that they are not pushed on too much during their earlier stages, otherwise they may be over before the time required. The bulbs of the variety *platyphyllum* are large, and composed of fewer, but larger scales than those of the ordinary *L. auratum*, while bulbs of the other two are, as a rule, a good deal smaller. Another Lily of the same section which flowers in the open ground generally towards the end of August may be brought on under glass to bloom earlier than this. It is the well-known *L. speciosum*, of which numerous forms are now in cultivation. This Lily is one of the most satisfactory of all for flowering in pots, as it is not so liable to die off as *L. auratum*, and can be depended upon to flower well. In an exhibition of Lilies during the month of August the different varieties of *L. speciosum* would no doubt be largely represented. *Lilium tigrinum* would flower about the required time, and of it there are some distinct varieties. If needed for blooming in pots the choice is, however, limited, as the ordinary Tiger Lily and its double-flowered form do not succeed at all well under such treatment, but the variety *splendens* or *Leopoldi* is very satisfactory when so treated. This retains its foliage well, which is not the case with the others, and the red flowers spotted with black are very distinct from the lighter tints of *L. auratum* and *L. speciosum*. Of newer Lilies we have *L. Henryi*, which may be had in flower about that time, but it is really far more satisfactory when planted out as at Kew than when grown in pots; still, under these latter conditions its colour makes it very noticeable. *L. nepalense*, one of the most distinct of all Lilies, might perhaps bloom in the early part of August, but its gracefully recurving blossoms are, as a rule, later than this in expanding. This Lily requires careful treatment, and it is very seldom that one gets more than a single bloom on a stem. Occasionally the secondary blooms of *L. Harrisii* will be at their best about the beginning of August, but they are very irregular in this respect, and not to be depended upon for decorations. From the above it will be seen that at a Lily exhibition at that season of the year but a very small proportion of the species in cultivation will be represented, and indeed at no time could a very large number be got together. H. P.

### THE WINDFLOWER.

(ANEMONE CORONARIA.)

At one time the Anemone was largely grown for cutting for market, but that practice has ceased to a considerable extent. It is undoubtedly one of the brightest and most effective of spring flowers; and as well-established roots make a free growth and produce many blossoms, it is matter for regret that the Anemone is not more cultivated, especially as very fine strains are met with in some parts of the country. Dry roots are largely imported from Holland, France, &c.; they come over early in September. If they are planted in a rather deep rich loam, not too heavy, they make growth in late autumn and put forth flower in spring. The old florists preferred a friable loam of a gritty character. The soil was deeply dug and manured, and planting done from October until January. A bed was made and five roots placed in a row across it, 6 to 7 inches apart. They were planted 2 inches deep, the soil gently pressed upon them, and a covering of partly decayed leaves and manure placed on the surface to the depth of 2 inches. Some growers left this to decay and become incorporated with the surface soil; others would clear the mulch away and replace it with one composed of well-rotted manure. Water was freely given in dry weather. A bed planted in October would flower in May; those planted in January not until July. Well-established roots will frequently bloom in autumn, and this arises largely from the fact that it is a characteristic of the Anemone to again put forth

growth as soon as the roots are well matured. To prevent this in the case of choice varieties which were intended for exhibition in May it was a practice with the old growers to attempt a kind of root-pruning, namely, to cut partly through the roots in the soil, dividing them near the base of the root, and so preventing a second growth. But those who grow the Anemone for garden decoration, and who do not make a practice of lifting the roots as soon as the foliage has turned yellow for the purpose of ripening them off, are not at all displeased that it blooms again in autumn, though it may affect its spring flowering.

Dry roots planted in October should by this time have some leaves above the soil, and a little protection from severe weather is desirable. This can be done by top-dressing with rough leaf mould, with which is mixed some fibry loam, some well-decomposed manure, or half-decayed leaves. Such a loose and light dressing affords protection to the crowns of the tubers and to the young foliage springing therefrom, and the dressing as it decays becomes of value as a fertiliser.

Opinions will differ as to whether the double or the single varieties are the more attractive. For my part I prefer the single flowers, for their simple beauty. I think many of the double varieties have the appearance of being irregular and uncouth, despite their size and fulness; and for the same reason I prefer a single Tulip to a double one, or a single Daffodil to one that is double. But the variety of the Anemone affords ample for all to admire it and deem it worthy a place in their gardens. R. D.

### THE SHOW AURICULA.

THE figure of Mrs. Moore (Douglas) show Auricula at p. 77 is a reminder that soon the fancier will be busily engaged amongst his favourites. The flowering plants have all been arranged together by themselves where they can be well cared for, beginning with the green edged, the most difficult class in which to obtain high-class flowers. There is a decided tendency amongst seedlings raised from the choicest varieties of this class to come with the margin slightly dusted with farina or meal, as it is termed. A high-class variety is only produced after long and patient waiting. Some may say the rarity of a plant makes it more valuable to fanciers, and doubtless this is so in Auriculas as well as the more aristocratic Orchid. I have been trying for many years to obtain a good green-edged Auricula, and have obtained one in *Abbe Liszt*. This is the only one that has been good enough to send out, and yet people think they are hardly dealt by if they do not get some sterling novelties out of a 2s. 6d. packet of seed. Out of 1000 plants I have saved half-a-dozen, and after growing them again have reduced them to one. Of course, this excessive weeding out may seem a too fastidious way of dealing with the Auriculas, but there is no other way in which they can be brought up to the present high standard of excellence. The florists of long ago valued the show Auricula even more than we do, for Hogg, who wrote in the early years of the present century, tells of a plant of Auricula green-edged Colonel Taylor which was sold for five guineas. A new and rare green-edged Auricula in these days would not be valued at more than one guinea.

I like to see the Auricula plants well frozen early in the year. Our plants of both show and alpine are still well frozen in the garden frames, and herein I think the old growers had the advantage, for their plants were free from the troublesome Auricula aphid. I fancy this pest is kept under when the plants are well exposed during the winter; whereas it lives and thrives in a house from which frost is excluded by the use of a heating apparatus. Many persons fancy that this parasite is very injurious, and turn their plants out of the pots periodically to remove it from the roots. This frequent disturbance of the roots is very injurious to the Auriculas and checks their growth very much. The insect does not

seem to do any harm if it is kept away from the neck of the plants, and this can easily be done with a small brush and fine tobacco powder. Pay particular attention to the seedlings of the show varieties to get them pricked out, because unless they have a good start early in the year they will not be strong enough to give good flower-trusses next year. The alpine Auricula makes much better growth in a season, and really does better planted out in the open garden; in fact, the show Auricula may also be planted out, and will be much less trouble. The young plants should be set out in some shady position away from any drip. The Rev. F. D. Horner plants his seedlings out in a well-prepared, open border. I noticed that even in his North Yorkshire garden he had made an arrangement for shading the plants with light tiffany during the summer months. Surface-dressing Auriculas was quite recently a universal custom amongst fanciers, and they did it because such was the usual custom. This custom some of us have found out had better be discontinued. A considerable quantity of soil was generally taken out from amongst the surface roots, this being replaced with a mixture of very rich material, but observant cultivators found out that even up to the time when the plants were in full bloom the roots did not penetrate into this strong mixture. I tried a mixture not so strong, and one into which the roots would grow freely if they were potted in it, but the plants evidently do not form roots at least near the surface at the time of flowering, for they made very little use of this mixture even when only moderately rich. J. DOUGLAS.

**Colour and form in show Auriculas.**—"D. C." writes asking if a crooked flower like Mrs. Moore should be admitted in a selection of choice Auriculas. I beg to say that Mrs. Moore is not a crooked flower, as can be seen by examining any well-grown truss of it. When it was first exhibited it received several first-class certificates of merit from various floral societies, the judges being the best florists at the time. I also gave the colours as approved of by the "Auricula Fancier." For my part I would be delighted to see Auriculas raised with a ground or body colour of violet, deep blue, plum, or scarlet. I esteem many of the old florists, and greatly admire them for the good work they have done in preserving for us these beautiful favourites, when the fashion of the age was for ribbon borders, panel gardening and carpet bedding, but in the colour and form of their flowers they were too much wedded to routine, and they remind us rather of what poor Oliver Goldsmith wrote of his celebrated countryman Edmund Burke. Our old-fashioned florist saved from his seedlings only the flowers which he knew would be admired by his brother florists. Any other garden varieties outside the range of the standard of excellence aimed at by the florist were not tolerated in his garden, although I am informed some of the rejected Auriculas were sold to cottagers at a penny per plant in the good old times.—J. DOUGLAS.

**Violets.**—The border likely to be required for the preparation of plants for another season may receive attention so soon as the weather will permit, breaking it down with the fork, and, if the natural soil is rather on the stiff or light side, adding a bit of heavier stuff or some leaf-soil as circumstances demand. It should be so workable at planting-time as to allow for a light treading, which has the effect of settling the soil down and admitting a more rapid formation of root. I used to dibble the runners straight from the plants on this border, but finding they were a long time making headway if the weather came hot and dry, I have resorted to the plan of putting them for a time rather thickly in a frame, shading a little until root action commenced. The very best plan if time will allow is to tie a piece of damp Moss round each runner, placing them for a time in the frame; they can then be lifted out with all the tiny roots intact, and will start away at once. A south-west border is the best site.—E. BURRELL.

SUNFLOWERS AT TRESSERNE.

IN the autumn of 1892 I replanted about 2 acres of vineyard, and the winter of 1893 being unusually severe, it was found when spring came that a large number of the little had perished. As they could not be replaced until the autumn I determined to fill the vacant spaces for the time being with tall-growing annuals. Early in May I had some of Vilmorin's best strain of giant Sunflower and Castor-oil plants sown in boxes, and towards the end of May several thousands of little seedlings were planted out. Shortly afterwards I left for England. When I returned to Tresserne in August I found a perfect forest of Sunflowers and Ricinus. It was a wonderful and beautiful sight. When we walked among them they towered above our heads and shut out the sky. Visitors to the garden were much impressed by the unusually beautiful effect. Last spring myriads of seedlings appeared, and I felt much distressed in having to destroy them, but in the interest of the new vineyard all could not be suffered to grow, so only a few hundreds were allowed to remain. These were the plants which attained to such gigantic proportions last autumn. There appeared to be about equal numbers of the branching and single plants, and they both showed the same tropical growth. Many of the single-flowered plants were quite 20 feet high, and the individual blooms were about 22 inches in diameter. The foliage was equally fine, and, indeed, in every respect the plants showed a luxuriance truly remarkable. When in November they were cut down and the stems piled together they made quite a large stack. I have no way of accounting for such unusual growth beyond the favourable position of the garden, which slopes towards the Lac de Bourget in a south-westerly direction. The soil, naturally excellent, had been well trenched and manured for the plantation of Vines. The seed, which originally came from Vilmorin, was self-sown last year. More rain fell last spring than was the case the previous year, and that would probably be an additional aid to the plants, which last season averaged from 2 feet to 3 feet more in height than these of the preceding year.

E. WILLMOTT.

BOG PLANTS.

I OFTEN wish, when I read Mr. Wood's instructive letters in THE GARDEN, that for his sake as well as our own his interesting place ran down to the river at the bottom of the Kirkstall valley instead of being confined to the drier land on the side of it, though I am not sure whether the bog plants he finds it so difficult to grow would thrive as luxuriantly near the pellucid (!) waters of his Yorkshire stream as they do in this Norfolk village. If the chimneys of the great ironworks at Kirkstall still smoke as they did when I last saw them, I wonder, not that he sometimes meets with plants that object to grow in his garden, but that he is so generally successful.

Fortunately, my grounds extend to the banks of a small stream, the river Yare, and the low,

marshy ground near it is a perfect paradise for bog plants. *Onoclea sensibilis*, for example, which he alludes to in your issue of January 26, p. 61, and which he thinks is injured by wet, becomes in my bog garden as truly a weed as it

most at home by the side of a ditch, where it creeps along quite down to the water's edge, the fronds being sometimes nearly 3 feet high. Speaking generally, I find many of the North American Ferns quite able to hold their own in perfectly wild places. I often wonder they are not more frequently introduced into the choicer parts of the plantations that often surround our English gardens. To anyone who, like myself, prefers to grow plants that require no attention and give no anxiety, I can confidently recommend for such a purpose the under-mentioned species, viz., *Onoclea sensibilis*, *Struthiopteris pennsylvanica*, *Osmunda cinnamomea*, *O. interrupta*, *O. spectabilis*, *Nephrodium Goldianum*, *N. intermedium*, *Poly-podium hexagonopterum*, *Asplenium angustifolium*, and *Aspidium acrostichoides*, and with a little more care and in suitable soil (the others will grow anywhere), *Adiantum pedatum*, *Aspidium munitum*, *Athyrium Michauxi*, *Cystopteris bulbifera*, *Nephrodium marginale*, and *Woodsia obtusa*. There are many other hardy exotic Ferns that will take care of themselves, or nearly so, and an admixture of these foreign species with English Ferns in the wild garden would make it a much more interesting place than it sometimes is. Mr. Wood speaks of *Tropeolum speciosum* as disliking wet, but it grows in my bog garden at a spot that is sometimes nearly under water in winter, and has been so during the last few weeks several times and for days together.

On the same page as Mr. Wood's letter, another of your correspondents ("A. D.") says that with him *Primula Sieboldi* proves impatient of moisture. He will be surprised to know that the only situation I care to grow this beautiful plant in is the wet, waterlogged soil I have described, because I find it does so much better there than anywhere else. Two years ago I dug up a great patch of it, and sent it to the spring show at Norwich without any preparation at all, where it gained a first prize in a small collection of pot plants. *Primula japonica*, too, will not grow anywhere with me as I like it to do except in wet ground, where it flourishes and seeds about like a perfect weed. I quite agree with your correspondents that some plants must be kept dry in winter, as they are at home, for example, on the Alps under the snow, or in Canada, where the ground is hardened many feet deep by 60° of frost. In such localities it is either winter or summer, and plants are either resting or growing. In this country the winter and spring, with their unceasing changes of the temperature of the air and the condition of the soil, are simply bewildering to plants with delicate constitutions that come from countries where they live in a climate they can depend upon, and some of them cannot adapt themselves to the different state of things. Some plants cannot be cultivated at all except at the expenditure of an amount of trouble out of all proportion to their value. Fortunately, there are many others that seem absolutely indifferent to the vagaries and inclemency of our English climate if only they can have plenty of moisture in the growing season. One thing, however, many

A giant Sunflower at Tresserne. Engraved for THE GARDEN from a photograph sent by Miss Willmott, Warley Place, Essex.

is in the Canadian swamps. I give it no care or attention whatever, but let it run about just as it likes, and it thrives and holds its own in my woods with the rank-growing marsh plants as well as any English Fern could do. It seems

even of these object to, and that is smoke and impure air. I think some of Mr. Wood's difficulties must be due to the Kirkstall forges on one side of his garden and the Leeds factory chimneys on the other. I should like some day to have the opportunity of showing him how thoroughly at home such things as those already named, *Cypripedium spectabile* (which I remember he mentioned in your columns some time since) and many other plants which are often thought difficult to grow can be, even though growing in soil which is saturated with moisture all the year round, and sometimes even submerged in winter.

Cringleford.

F. W. HARMER.

#### NOTES ON HARDY PLANTS.

**Sarracenia purpurea.**—With regard to the hardiness of this species, of which I believe there are several varieties, I find it in my Yorkshire climate fairly so, but it would certainly not be safe during its first winter unless well established. To succeed with this plant it is important to begin with good roots, planting them in the early summer so that they may become well established before winter. Under these circumstances I find it hardy. I have proved that strong crowns with a good piece of woody rhizome and a few fresh leaves are not only the likeliest specimens to grow, but if set in 9 inches or 12 inches of rotten Sphagnum and peat, with plenty of silver sand to make this fibrous stuff somewhat solid, plenty of roots are rapidly formed in the first summer. Of course, when I say plenty of roots I mean in the relative sense, because the *Sarracenia*s do not possess at best a dense set of roots. I think it also advisable to cover over *Sarracenia*s in the open with a thickish covering of dry Bracken during winter. This enables the plant to keep in a more verdant state as regards its old leaves, and such when exposed in spring are better for a vigorous start compared with plants whose leaves are all browned.

**Saxifraga Burseriana.**—One recalls this charming alpine from seeing its prominent buds in the first month of the year, waiting only for a spell of a week's fine weather to become expanded. By the kindness of Mr. Boyd I am now possessed of some five or six varieties of this species, but I have recently found that other than the plants that he has raised are existent with very marked features of distinction, and, like many other species that one could recall, some of the beautiful varieties must have existed for a long time. From out-of-the-way gardens I have received plants with features almost as wide from what I took to be my typical plants as if they had been other species entirely. At the time I supposed it might merely be a difference caused by soil or climate, but after growing them for a year under the same conditions as my own, I see the distinctions maintained. I merely mention this, as it might be interesting to know this plant may be had as variable from seed almost as the well-known *Saxifraga longifolia*. It is not a case of having to throw out bad forms, because I have never yet seen an indifferent one. All the varieties I have seen are well worthy of culture.

**Meconopsis Wallichii.**—May I mention, anent the note of the Rev. Mr. Page-Roberts (p. 31), that I can conceive it quite possible for his experience with this plant to be different from mine. Different garden conditions would account for it, for one thing. The two facts I would wish to state, however, are, first, that I never tried this plant in what I understand by the term "total shade," and I am under the impression that I gave with the sunny position one also of extra moisture for the roots. With many plants to be grown in one condition without the other would make all the difference in the world. I have always grown this plant and also *M. nepalensis* at the bottom of sunny pieces of rockwork, where the slopes acted as a sort of watershed for an

extra supply of wet, and, it may be added, wet of the most healthful kind, seeing that in such parts—among stones and in sunshine—there could be neither stagnation nor sourness.

**Phyteuma comosum.**—There are two plants of this name, and, what is more, both are in commerce, so that it is somewhat essential that the kind intended should be thoroughly understood. The plants are widely distinct, and once seen, a novice could scarcely mistake the one for the other: and, indeed, the descriptions of the respective authorities will be sufficient for those who have the means of referring to them. The most distinct form is *comosum* (Linn.). *P. comosum* (Vill.) is a much coarser plant with a totally different habit, and growing 1 foot to 1½ feet high, and it is synonymous with *Alph. de Candolle's comosum*, which that authority classes as a variety of orbiculare. The much-sought-for *comosum* (Linn.) grows but several inches high, has rigid foliage, somewhat contorted and toothed like Holly, borne on very short stalks. For the size of plant the flowers are both large and numerous, but I think the culture requires to be somewhat special. The half-woody root-stalks are better for being kept-dry about the collar, but the more extreme parts of the roots should reach good soil. The plant has also a decided preference for limestone. I grew my most successful plants with the points of the stronger roots in rich moist loam, with quite 3 inches on the surface of gravelly soil and lime-chips. J. Wood.

Woodville, Kirkstall.

#### FLOWER GARDEN NOTES.

**WHITE FLOWERS.**—Hardy white flowers useful as border plants and in most cases for cutting range from tree-like shrubs down to the dwarf white Harebells. In the shrubs one of the best is probably the Fringe tree (*Chionanthus virginicus*), handsome in foliage and beautiful as any Orchid when in full flower. It is not so widely known as it should be. The fact, however, that it was shown as a forced plant in very fine form once or twice last season will doubtless have the effect of increasing the number of its admirers and planters. It must be noted that it is quite as good out-of-doors as in the show tent. It would be advisable, if possible, to have another name for this plant, unless it is simply known as the Fringe tree. The scientific name gets sadly mixed up with the better-known *Chimonanthus fragrans*. A very fine shrub, growing to a height of 10 feet, is *Spiraea arizifolia*; a clump of this in a prominent position makes a brave show when covered with the huge spikes of white flowers. This, by the way, is not such an essentially moist border plant as are the dwarfier *Spiræas*. I have seen it very fine on poor dry ground. The grandiflorus form of the Mock Orange is a great improvement on the type, being nearly or quite twice the size and of better substance. Two dwarfier shrubs that will be found very useful are the white Broom and that beautiful double *Spiræa*, *S. prunifolia* fl.-pl.; the one is a capital plant for covering dry, sloping banks, the other equally good for clothing portions of wall or old tree stumps. Turning to the larger herbaceous plants that furnish us with white flowers, all the *Spiræa* family make capital border plants, but the best for cutting are *palmata* alba and *astilboides*. The latter is the least satisfactory in growth of any of its class; it wants a moist, partially shaded border and the ground to be well prepared. We find the long spikes of *Galtonia candicans* very useful for cutting. Those starting the culture of this plant are advised to plant in occasional open spaces that may occur in beds of American plants or young shrubberies rather than to mass it alone in the open. The long flowering stems of the taller *Campanulas* are very acceptable for large vases, and so are the spikes of the white Foxglove. Of the white varieties of *Antirrhinum*, *Phlox*, *Pyrethrum* and *Sweet William* it may be said that they are as useful for the flower basket as for the border. Last season was a disastrous one for *Sweet Williams*; the foliage was badly

attacked with disease early in the year, the remedial measures employed had not the effect of checking its progress, and the size of flower-spike was considerably lessened; indeed, in many cases the display was very poor. Smaller herbaceous plants bearing white flowers that are always acceptable would commence with a good strain of white *Polyanthus* and run on with white *Pinks* and *Carnations*, the various forms of the *Poet's Daffodil*, the double white *Yarrow*, *Veronica spicata* alba, &c., whilst an occasional picking from a good white *Viola* comes in handy for small glass bowls and vases. There is now a radical change in the type of flower employed for cutting, as one sees extra-sized blooms of white *Pæonies* used.

**SPECIALITIES.**—There are some herbaceous plants, hardy and easily grown, that have come rapidly to the front within the last few years, very beautiful in quantity on the border, and for cutting almost equal to the choicest hot-house flowers. It is not that these are anything new; on the contrary, they might almost rank with old-fashioned flowers; but rather with the growing taste for such things, planters—having recognised their beauty and adaptability for vase work—gradually took measures to see that they should be well represented in the flower garden. Take, for instance, the *Montbretias*. Some, at any rate, of the family were introduced as far back as 1825, but it is only very lately that it is the rule, and not the exception, to find them even in large gardens, and yet it is safe to assert that there is no more acceptable flower for the vase, whether it be the spike in its entirety for tall, or the side shoots for shorter glasses. Growth was early this year with the *Montbretias*, and the young blades are cut down nearly level with the ground by the late frosts. The flowering season will in consequence be a little delayed and individual spikes not quite so fine as usual. This, however, will comprise the amount of harm for which the late severe weather is likely to be answerable. Another "special" plant, very different to the *Montbretias*, but which may be here appropriately mentioned, as it is often associated in a cut form with these Cape bulbs, is *Gypsophila paniculata*, a plant that has indeed risen very rapidly in favour. Little known a few years back, except in hardy plant nurseries, it is now a very general favourite—evinced by the fact that there are few summer shows where it may not be found both as a pot plant for groups and in cut form. It is, fortunately, a plant of very easy culture in ordinary garden soil, tiny clumps producing the first season very large heads of flower. Like the majority of the better-class herbaceous plants, it likes a bit of good soil, to which a little manure has been added at planting-time and an annual winter mulching. Following up the thought expressed earlier in these notes that some of the common flowers take rank as among the most delicately beautiful, one must say a good word for *Saxifraga umbrosa*, the old London Pride, a charming flower for vases. A less known plant, but also in its way very beautiful, is *Heuchera sanguinea*. *Alstroemerias* might be grown more extensively where quantities of cut flowers are required; they possess the merit of standing well in water. Essentials towards their successful culture are a sunny, well-drained, trenched border, fairly deep planting and a heavy surface mulching. Writing of hardy flowers brings the reminder that as the time for the formation of schedules in connection with cottage garden shows is now fast approaching, it is as well to draw attention to the necessity for accuracy in the wording of those classes that deal with collections of cut flowers. They should be classed as hardy herbaceous or as annuals, as the case may be, and not indoor or outdoor flowers, or one often gets varieties that may be grown out of doors through the summer months, but which have actually come from the shelter of a greenhouse. Also where practicable it is advisable to give one or two prizes for the best flower garden. One is met sometimes with the remark, "But it is so difficult to judge a flower garden," but I do not think there need be any real difficulty, for a true cottage flower garden

(always subject to order, neatness and good arrangement) should be one from which the greatest amount of pleasure is derived, planted to secure a long flowering season—not a display for two or three months and bare earth the remaining nine, but something to look at and admire the greater part of the year. E. BURRELL.

Claremont.

ORCHARD AND FRUIT GARDEN.

PEAR BEURRE D'AREMBERG.

THE accompanying illustration shows a fruiting branch of that good Pear Beurre d'Arenberg, which comes into use during December and January. It is a tree that bears well either as a cordon or standard, is hardy, and as a stock the Pear or Quince may be chosen, as it does well on both. The flavour of the fruit is rich and juicy.

GRAPE MRS. PINCE.

As grown in these gardens, Mrs. Pince is a grand Grape, the bunches being large, well shaped, and the berries excellently coloured. Taking one season with another, the bunches weigh individually from 5 lbs. to 7 lbs. The largest bunch I ever had of this variety weighed 9½ lbs., and was well finished. One of the most fertile causes of failure is over-cropping; in fact, I know of no other variety of Grape which suffers to such an extent from this evil as Mrs. Pince. Being naturally a large-bunched variety, some people cannot resist the temptation to leave more bunches than the Vine can possibly finish; consequently the berries fail to finish, taking on that "foxy" tinge and commencing to shrivel early. Not only are the Grapes spoiled for the season, but an inherent weakness is laid in the Vine, with the result that the following season the berries fail to set properly. Far better is it to limit the number of bunches annually, with the certainty of their finishing up well. A long season of growth is also needed, the Vines being started the first week in March. A little warmth is kept continually in the pipes at night right throughout the season; in fact, this is the practice I adopt with all Grapes, whatever the nature of the season, a little ventilation also being kept continually on. If the vinery is kept too hot and close, the Grapes are ripened up too quickly; whereas time is needed for laying on colour. As this treatment produces both good Alicante and Lady Downe's, there is no need to have a separate structure for Mrs. Pince. A dense shade about the bunches is also detrimental to a good finish. The laterals must be thinly trained, as quite as much light is needed for this variety as for Muscat of Alexandria. I came to this conclusion on noticing that the sides of the bunches which were most exposed to direct light took on the deepest colour. Mrs. Pince is growing here at the west end of a lean-to vinery; consequently more light reaches the bunches than if the Vine were grown in the middle of the house.

I have no trouble in securing a good set, but the precaution is taken of drawing the hand over the bunches daily whilst in flower. If any other variety is in bloom at the same time, the hand is drawn over these first to gather pollen. The temperature also at this period must be well maintained both by night as well as by day. If the Vine should be in flower during a wet and dull time, the atmosphere must be kept buoyant by the use of more artificial heat. A. YOUNG.

Abberley Hall, Stourport.

**Apple Loddington Seedling.**—This is a large kitchen variety, and may be termed a mid-season fruit. My experience of this Apple is that it closely resembles the Keswick Codlin as regards

its cropping qualities, as it rarely fails to bear. I do not know of any kind more suitable for grafting on to old standards which are worthless. I saw some old standards of this variety last season in the west of England doing grandly. These had only been grafted a few years, and I was told a good price was obtained for the fruits. Many growers who have old, worthless trees and who may wish to regraft would do well to try this variety. It also does well on the Paradise.—S. H.

**Rivers' Early Nectarine.**—The favourable descriptions given of this early Nectarine by growers who had proved it prompted me to secure a pot-grown tree for permanent planting in the early house, believing that the slightly extra cost would be a gain in early fruiting. I previously had established trees of Lord Napier and the old Elruge, which, however, did not ripen their crops till the end of May, while Alexander, Early Beatrice, and Waterloo Peaches were ready in the first week of that month. The new Nectarine was planted towards the end of December, and by the middle of January was in full flower. Early blooming does not always imply a corresponding early ripening of the crop in Peaches or Nectarines, but it certainly appears to justify the

the hedge at the bottom of Mr. Mannington's garden, and always had a stunted appearance. With me it is free from canker, having a slender habit of growth. It makes a good pyramid and espalier, and comes into bearing early. Mr. Mannington was a butcher by trade and an enthusiastic pomologist, taking a great interest in all kinds of fruit. I used to often see him sitting at his door when passing in the summer-time, and he delighted to point to the large Wistaria that covered his house and shop. He died at the house he had occupied for years on September 19, 1880, at the ripe old age of ninety-three. Often as I pass the old shop I think of the man who did so much to encourage fruit cultivation in this neighbourhood, and so long as the Apple that bears his name is in existence his perseverance in trying to improve our fruits will be borne in mind.—H. C. P.

**Apples and canker.**—According to my experience, King of the Pippins is liable to canker very much when worked upon the Crab stock in heavy soil if the roots are not kept near the surface. This is one of the varieties that can be depended upon to fruit every year. Trees of it planted in the ordinary way will show canker the second year when growing in heavy cold soil, but by lifting them on to the surface and mounding the roots up the canker will be checked, the trees making a clean free growth almost directly afterwards. Trees of this variety planted deep in a cold soil will produce a quantity of fruit, but many of them will be badly affected by the Apple scab. My experience of canker in Apple trees is that it is the result of an unsuitable soil, aggravated by deep planting.—E. M.

— Mr. J. Douglas (page 75) is quite correct in inferring that I held no bigoted opinion on the subject of the liability of Apples on the Paradise stock to canker. Two cases, however, have come under my observation in which canker has attacked the Paradise and spared the Crab. In one case the trees on the Crab are three years older than those on the Paradise, were planted three years earlier, and came from a different nurseryman. The two varieties of stocks occupy adjacent plots of land; both looked in the best of health when planted, but a third of those on the Paradise are now affected by canker,

Pear Beurre d'Arenberg. Engraved from a photograph sent by Miss A. Worsley, Rodney Lodge, Clifton, Bristol.

while those on the Crab are free from it. In the other case, which as an example is still more striking, the trees, on Paradise and Crab, are planted alternately in the rows, each row consisting of one variety of Apple. All these trees were planted at the same time and came from the same nurseryman. In some of the rows the trees on the Paradise are cankered, while those on the Crab (of the same variety) are clean. It has occurred to me that the dwarfing stock by stunting the tree may, under certain circumstances, render it liable to the attacks of a disease which the freer stock is vigorous enough to grow away from, if I may so express it.—S. W. F.

advance claimed for it by the raisers in point of earliness in ripening. Lord Napier will be fully three weeks later in coming into full flower, although started early for the past three or four years, when the new Early Rivers probably has not been forced at all. This latter has, like Lord Napier, very fine flowers, and must have close attention in fertilising to get them to set properly. When better known and the cost within easy reach of the general grower, this new variety must take a foremost place for early forcing, and if it ripens as reported, three weeks in advance of Lord Napier, this will not lose its value because of the succession it would furnish.—WILTSHIRE GARDENER.

**Apple Mannington's Pearmain.**—I was very pleased to see this Apple spoken so highly of on p. 76. On our cold soil it does well, and is one of the finest late Apples in cultivation. It is, however, seldom seen on the exhibition table on account of its size, and for this reason is not so extensively cultivated as it deserves to be. Those, however, who appreciate quality would do well to grow this. The fruit should be allowed to hang on the tree till late in the autumn, and if afterwards stored in a cool place it will keep sound till April. The original tree was found growing in

**Coloured Vine leaves.**—The note (p. 33) by "W. G. C." is quite opportune, and an interesting subject as well. There is not the slightest doubt but that the constituent properties of the soil have a marked effect upon the colour of Vine leaves. Nowhere in England have I seen such high colour as on the Vines in Scotland. A really splendid feature was made at the late Edinburgh Chrysanthemum show by Messrs. D. and W. Buchanan, of Kippen by Stirling, with Vine leaves only. For three days a ready sale appeared to be going on, so eager were the visitors to purchase these leaves for vase decoration. Black Ham-

burgh was especially golden in its colouring, and so were Gros Maroc and Alicante, not that dingy yellow which is very common in most vineries upon the approach of autumn, but a colour which is best described as a rich lustrous yellow. Barbarossa was exquisitely blotched with crimson, and so were Madresfield Court and Gros Colman. Alnwick Seedling was splendid with irregular blotchings of gold and green. From Mr. Buchanan I learnt that the soil in which the Vines were growing was especially porous, being light and warm, and therefore more adapted to natural colouring than where the soil is heavy and consequently colder. At the same exhibition classes were provided for vases or epergnes dressed with Vine leaves only, and an exceedingly rich display the dozen well-dressed stands made. In fact, no exhibit in the whole of an exceptionally large exhibition created more interest than the vases alluded to. In the vineries at Newbattle I noted also the same richness of colouring in the well-developed leaves of nearly all varieties. There again the golden tinge of the Black Hamburgh and Alicante was especially bright. It may be that here in the southern counties the foliage ripens and falls off more quickly than in the north, where the atmosphere is cooler in the autumn. Even as far south as Torquay, where the soil is particularly porous, I have not seen anything approaching the magnificent colouring alluded to in Scotland. At the Hull show an attempt was made to utilise coloured Vine leaves in association with cut blooms of Chrysanthemums, but the result was anything but satisfactory, owing mainly to the dinginess of the Vine leaves.—E. M.

**Apple Mere de Menage.**—Some growers find a difficulty in getting this variety to fruit freely, but my experience is quite the reverse. I have forty trees of it, and without exception they all do well. It is just the Apple to grow in soil that is heavy and retentive, provided pruning is not carried out upon too restrictive a method. By allowing the leading shoots free extension, fruit spurs are produced in quantity. Better crops are thus obtained from quite young trees. Apples from well-managed trees of this variety grow to a very large size and are of exquisite colour. As a cooking Apple *Mère de Ménage* takes a high position, keeping quite plump until the end of January.—E. M.

#### YOUNG PEACH TREES.

For the past month I have been watching a number of young Peach trees very closely, and in particular have noted which trees shed the most buds prematurely. Once more it has been proved that bud-casting is more due to the inherent weakness, if I may so term it, of some varieties, and more especially those of American origin. Early in the spring of 1894 about thirty maiden trees in six varieties were planted in a span-roofed house 135 feet long and 14 feet wide, and, all things considered, they have done surprisingly well. They had really to hold their own against Tomatoes planted out in cross rows 3 feet apart in the same house. All the favour shown to the Peach trees only amounted to a little decayed manure mixed with the ordinary sandy loam in the house and a clear semi-circular rooting space 4 feet across. As might be expected under such conditions, the growth was not excessively vigorous, or at all events grossness was avoided, but being maidens and not stunted cut-back or trained trees they grew quite strongly enough, many of the leading growths being allowed to form secondary shoots. These latter were freely thinned out, only those best placed for laying in being reserved. It should also be added that they were extra strong, well-matured maidens, and were not cut hard back, but instead of this were trimmed in and shortened to a length of 3 feet, this just bringing them up to the roof trellis and enabling us

to dispense with longer-stemmed, and therefore more expensive trees. Thanks to the comparative poorness of the soil and also the abundance of light admitted to the trees through large squares of glass with only stout sash bars to support these, the wood, as a rule, was thoroughly well matured, so much so in fact that there are numerous fruit-buds on young wood  $1\frac{1}{2}$  inches in circumference. At first I was under the impression that Early Alexander would hold its fruit-buds well, but latterly they have tumbled off wholesale, so that not many more than a dozen will remain on each tree other than what are found on the twigs or spray, of which there is, unfortunately, very little. Nor is Hale's Early behaving much better. There will be enough flowers left to give a crop, and that is about all. Next to these, also on the hottest side of the house, comes Crimson Galande, and these trees are the worst ripened of the lot, yet they are certain to flower profusely. They were so late in ripening, that I scarcely expected to see flowers on the greater portion of the shoots, but with few exceptions they are there. On the opposite side Bellegarde has the warmest end, and these trees are very freely budded, rather more so in fact than I care to see them, a little more vigour being desirable in this case. All the trees, and some have grown much more strongly than others, of Sea Eagle are in a very promising condition, and flower-buds will be removed extensively. Curiously enough, this fine late ripening variety is usually the first to flower in a mixed house, and with me is well ahead of the rest. Princess of Wales completes the selection, and of this we have the best trees, some of them having fan-shaped heads 5 feet through. Without being particularly well ripened, the wood is yet sufficiently well matured, and throughout growths 3 feet long are furnished with fruit-buds. There are no signs of dropping in the case of the four last named varieties, and before these lines are in print they will all be in full flower. This does not add much to what has been advanced on the subject of bud-dropping in previous years, but it is corroborative.

Perhaps the thought will strike some of my readers that I need not concern myself greatly about the free flowering or otherwise of such young trees, as they will surely not be allowed to fruit this season. But they will, and the greater part of them will each be expected to produce not less than one dozen fruits. This they will do without prejudice to future prospects, the crop serving to check grossness, without, however, unduly checking progress. Planting maidens just prior to the commencement of top and root growth, and in good sunny positions, is a very different matter to sticking in trained trees among old-established trees, where, perhaps, they have to be started early and are constantly otherwise at a disadvantage. In our case the main stem broke freely and strongly, but the sides of the house being unfavourable to growth of branches to within 3 feet of the ground, no shoots were allowed to form below, and only four or five above that height. These shoots, having all the strength of vigorous young trees thrown into them, never checked in their growth, but divided and in some cases sub-divided, so that quite large trees were formed. As will be seen, this is simply a modification of the extension system, and the trees will be aided to spread on much the same lines. Very little pruning has been done, only the more weakly shoots required for laying the foundation of a serviceable tree having been freely shortened back, and two or three badly ripened ends cut off in the case of Crimson Galande,

already alluded to. All the rest have been reserved to their full length and laid in thinly, some of the stronger growths being depressed somewhat, with a view to checking grossness near the centres. They are so well rooted in the border they shared at one time with Tomatoes that I have every confidence in their capability not only to give a crop averaging a dozen apiece, but also for rapid extension. This time Tomatoes and Kidney Beans in pots will occupy the 3-foot width of border reserved for the Peach trees, and these, with Veitch's climbing Kidney Bean, will largely occupy the centre of the house till syringing may be safely discontinued, when Tomatoes will again occupy the centre.

It is the pampered, much-pruned trees that seem most disposed to bud-dropping, unless, indeed, it happens to be the variety that is at fault. When they are planted in a rich border of considerable extent and are hard pruned, the growth is too full of sap to be really fruitful, and the evil is aggravated accordingly. Severe root-pruning or a bad attack of red spider will perhaps be the means of bringing such trees into a more fruitful state, but as far as growers for sale are concerned, the less need there is for such violent remedies the better it will be for their pocket. Those who will insist upon following the old lines, and in particular zealously removing all secondary shoots as fast as they form, must not be surprised at the first-formed shoots becoming too gross to be fruitful. Whether the buds on these over-strong shoots are malformed, or, what is more likely, become disconnected when the wood is swelling the most rapidly, matters little; the result is what concerns us the most. Those who find their primary growths too vigorous to be fruitful should reserve two or more secondary shoots on these, and they will ripen under glass without fail, always provided they are well exposed to all the sunshine and light possible. Not only do the secondary growths form and retain flower-buds in abundance, but most of the ends of the primary growths will also retain their buds. If there is good room for extension, these leading growths should not be pruned, but the side shoots ought to be shortened to about half their length at a joint where there is a central wood-bud and two side flower-buds. Young trees treated in this manner quickly cover their allotted space or occupy the whole roof of a small house, if need be, and are fruitful from the first.

W. IGGULDEN.

**Melon Victory of Bath.**—While fruit growers are hankering after novelties in Melons, as in other things, older and better tried varieties are apt to be lost sight of in the craving for newer kinds. Although Victory of Bath has been grown close upon twenty years, it is still one of the best green-fleshed Melons we have. Not only is its flavour of the best, but it crops freely, and is not disposed to crack just when ripening should take place, as is the case with some others.—E. M.

**Apple Lady Sudeley.**—I grow over 100 trees of this Apple and think most highly of it. Here in our strong soil it grows well and bears freely, the richly-coloured fruit selling well. It should not remain upon the tree a day after it is ready to gather, as it quickly becomes mealy. I do not wonder at the thin crop obtained by Mr. Crawford from trees grown as horizontal cordons, because it is one of those Apples that fruit the best from the points of the shoots. For this reason the cordon method of growing it cannot be recommended.—E. M.

**Covering the stems of outdoor Peach trees.**—When at Barham Court in the autumn I noticed that all the stems of the outside Peach trees within 18 inches of the soil were covered with pieces of Oak bark. Mr. Woodward in-

formed me that he believed the stems swelled much more freely when protected from the fierce heat of the sun during summer. Certainly the trees in question were remarkably clean and luxuriant. I know of no material better calculated to answer the purpose named than Oak bark. Where this cannot be had, virgin cork would answer equally as well.—E. M.

**Apple Cox's Orange Pippin.**—To me it is an astounding assertion to hear that too much praise is accorded to Cox's Orange Pippin. In this neighbourhood and further south—Devon—it is considered the best dessert Apple, not only for its fine flavour, but also for the freedom of growth of the tree and plentiful crop that it bears. I have also heard it said that as a standard or half-standard tree it is a failure. My experience is the opposite. Here in a strong soil it grows vigorously, is free from canker, and crops abundantly, even when young. Bush-grown three-year-old trees planted in the autumn of 1890 produced fifty really fine fruits in 1893. No difficulty is ever experienced in obtaining 8s. per bushel for good samples, while as much as 12s. have been obtained.—E. M., *Swanmore Park*.

## ORCHIDS.

### HABENARIAS.

THESE cannot be regarded as popular plants, although some of the species, if well grown, compare favourably with others that obtain a far greater share of attention from orchidists. As some of the principal cultivators seem to have taken them in hand, however, it is to be hoped that others will follow their example, and that in future we shall see more of such fine species as *H. carnea* and *H. militaris*. The genus is widely distributed over the Old and New World, at least four species, or perhaps more correctly varieties, being included in our British flora. The culture of the tropical kinds is by no means difficult providing a sufficiently high and moist temperature be maintained. If newly-collected roots are procured they may with advantage for the first season be grown in a compost consisting largely of Sphagnum Moss, only a little fibry loam and potsherds being added. This will encourage the growth of the fleshy roots, which it is of the utmost importance to keep intact. Established plants require careful handling and should be potted in equal parts of peat, fibry loam, and good leaf-mould, with chopped Sphagnum and finely broken crocks to keep the mixture open. Opinions vary as to the best time for repotting, some cultivators choosing the spring for this operation, others maintaining that the most suitable time is immediately after flowering and before the stems die down. This is in order that the roots which are then produced are not afterwards disturbed. I have personally had good results from repotting at the latter season, but I am open to conviction, and I think it would be very interesting if those cultivators who have tried both would record their experience for the benefit of readers of THE GARDEN. While growing freely the plants may safely be treated as semi-aquatics, the soil at no time being allowed to get quite dry. Less water is of course required while at rest, and they must be kept during this period in a cool moist house. The hardy indigenous species are easily grown on a sheltered shady border or rockery, and if such as *H. bifolia* or *H. chlorantha* once become established, they thrive under trees or on the edges of shrubberies. They like a rather tenacious loam containing a good proportion of chalk. During the very dry summer of 1893 I lifted many clumps of these kinds while in flower from the woods in this

locality, and these are now well established on a large rockery under the dense shade of Beech trees, where little but Ivy and hardy Ferns can be induced to flourish. The hardy North American species thrive best in a lighter compost, Sphagnum, peat, and leaf-mould being the chief constituents. They should be grown in a sheltered position, and although they like shade in summer, this must not be too dense, as after flowering they require a certain degree of ripening. A covering of leaves or cocoa-nut fibre refuse should be applied during winter to all the hardy kinds, and a sharp look-out must be kept for slugs and other insects in the spring.

*H. BIFOLIA* is a native of Britain and common in woods and pastures. The flowers are produced in upright spikes; they are white and deliciously fragrant, especially in the evening or after a shower.

*H. CHLORANTHA* is a larger growing and flowering kind. The nectary of this is more elongated, forming a kind of spur. This is not so common as *H. bifolia*. There are many intermediate forms between these differing both in colour and size of flower. This is also sweetly scented, and a fine plant for a rockery.

*H. ALBA* is a very pretty little species, common in some parts, but rarer in others. It is not so strong in growth as the preceding, and should have a little peat or leaf-mould in the compost. The bloom-spikes are about 6 inches high, and bear about a couple of dozen of the pretty little white flowers in late summer.

*H. VIRIDIS* is, as the name implies, a green-flowered kind, and not so ornamental as either of the preceding. It is easily grown, however, and should be included in representative collections. This also thrives well under trees in a damp situation, where it grows about 6 inches high.

*H. BLEPHARIGLOTTIS* comes from North America, and is quite worth the little trouble necessary to grow it well. The lower leaves are oblong, green, the spikes leafy, and bear a large number of flowers, white, with a delicately fringed lip. It attains a height of about 20 inches, and has a very graceful effect when in flower.

*H. CILIARIS* grows over a foot high and is somewhat similar to *H. blephariglottis*, but the flowers are bright orange. This is also a native of North America, and though an old plant in cultivation is not often seen.

*H. FIMBRIATA* is a fine strong-growing species from the same country. It produces in summer long spikes, bearing a number of purple flowers about an inch across, with a broad fringed lip.

*H. CARNEA* is an exceedingly fine and showy species recently introduced from Singapore. The flowers are large and bright flesh colour, fading to white. The leaves are deep green with white spots, making a very attractive plant even before the flowers open. It requires the heat of the East India house.

*H. MILITARIS* is the brightest and showiest in the genus, being of the most brilliant scarlet in front, the hooded portion lighter. The spikes are leafy, crowned with loose racemes of flowers, somewhat resembling a very brightly coloured *Calanthe Veitchii*. This is a native of Tropical Asia, and flowers in September and October.

*H. MARGARITACEA* is not a showy-flowered species, but has prettily variegated foliage. The pure white blossoms are produced in summer.

*H. SALACCENSIS* is a native of one of the Sunda Isles, and grows a foot high. The loose racemes of flower are not very attractive. The petals are narrow, dingy red, the sepals and lip greenish white. It blossoms in May and June. A species named

*H. CINNABARINA* was introduced some two years ago. The flowers of this kind are described as cinnabar-red, with deeper spots upon the sepals. H. R.

**Epidendrum cochleatum.**—This is a curious and distinct species which, although of very early

introduction, is now seldom met with. It appears to have first flowered at Kew over one hundred years ago, and is a native of the West Indies and Central America, where it has a very extensive range. It is also reported to have been discovered growing in very limited numbers within the United States of America. The peduncles grow erect and terminate in a raceme of from five to eight flowers. These have greenish-white sepals and petals and a curious concave lip, which is pale yellow blotched on each side with maroon-purple. The name is derived from the formation of the lip. It should be grown in the Cattleya house. It is now nicely in bloom with Mr. H. Grubing, of Harrow Weald.—W. H. G.

### ANGRECUMS.

NOT many of the species of this fine genus receive the attention they deserve from cultivators, but why it would be difficult to say, as they are nearly all free-flowering, useful plants. The larger-growing kinds when in good condition are very ornamental even when not in flower, but when well flowered they are truly noble objects. These should be grown in the warmest house, and may be arranged on the central stage, as they need not be close to the glass. A good light position is, however, necessary, and the plants thrive best in a somewhat drier atmosphere than *Acerides* or *Phalenopsis* require. This latter is not absolutely necessary to their well-being, but I mention it because, in arranging a miscellaneous house of plants, consideration of these small details is of importance, and the closer the wants of the individual species are studied, the greater will be the success of the cultivator. They must be grown in pots large enough to take the roots easily, and these should be filled rather more than half their depth with potsherds. Clean Sphagnum Moss and charcoal should be used for the compost, the fresh-growing points of the Moss being dibbled neatly over the convex surface. The smaller-growing kinds are most satisfactory in small wooden baskets or shallow pans suspended not far from the roof glass in the same house. The baskets have a more rustic appearance, and the plants thrive equally well in either, but they usually transplant better from the pans than when the roots have become much entwined about the rods of the baskets. These also like growing Sphagnum about their roots, but only a mere surfacing is required, as the latter will not thrive if deeply imbedded in the Moss. They must never be dried, but while resting less water is, of course, required than during the growing season.

*A. ARTICULATUM* is a pretty dwarf-growing kind, the leaves being somewhat wedge-shaped, about 5 inches in length. From the axils of these the many-flowered racemes are produced. The blossoms vary a good deal in size, form and length of spur, this latter being very fine, and when several are seen at a distance they have almost the appearance of a deep white fringe.

*A. CAUDATUM* grows about a foot high and produces in summer long racemes of flowers. These are not very attractive in colouring, but remarkable for the tail-like spur, which attains a length of about 9 inches. This rare species is a native of Sierra Leone.

*A. EBURNEUM* is a very large-growing kind, with light green, leathery leaves 18 inches in length. The flower-spikes are produced in winter and early spring and last a very long time in perfection. They are rather stiff in appearance and the flowers are greenish white, with the exception of the lip, which is of the purest white.

*A. EBURNEUM SUPERBUM* is superior to the type, being larger and wholly pure white.

A. ELLISI is a charming Orchid, blooming in mid-winter and sweetly scented. The flowers occur on gracefully arching racemes and are pure white, with the exception of the brown-tinted spur. This was named after and introduced by the late Rev. W. Ellis, who was a distinguished traveller and writer on Orchids.

A. SANDERIANUM, also known as *A. modestum*, is of the dwarf-habited section, growing only a few inches in height. The leaves are deep shining green and form a delightful contrast to the pure white flowers. These are produced in spring and last a long time if kept dry. They are small, with a spur 4 inches in length and a rather broad, pointed lip.

A. SESQUIPEDALE is well known and a truly magnificent Orchid. The spikes bear from two to four flowers, each 8 inches across, with a spur occasionally 18 inches in length. This grows very strongly, about 2 feet high, the leaves deep glaucous green, and 12 in. in length. The late-flowering form of this Orchid is the better, being larger-flowered than the type. Occasionally, owing to being kept too cool during the winter, the lower tiers of leaves fall, giving the plants an untidy, lanky appearance. The present is a good time to improve such plants by cutting them off below the principal roots and setting them with the lower leaves resting on the compost. This and all the species named above, except *A. caudatum*, are natives of Madagascar. There are many other fine species in the genus, but these are perhaps the best known and most desirable. H.

**Calanthes at Harrow Weald House.**—This most useful winter-blooming Orchid is exceedingly well grown by Mr. Rapley, and for some considerable time past a fine display has been maintained. *C. Turneri* is largely grown, and its white flowers are very welcome after those of *C. vestita lutea* and *C. v. rubro-oculata* are over. *C. Turneri* is a very distinct species from Java, and produces finer spikes, with more blooms, the rich rose coloured eyes contrasting well with the other pure white parts of the flower. The charming hybrid *C. Veitchi* is here seen to perfection, for not only is there a large quantity, but the flowers are exceedingly fine, some of the spikes measuring over 4 feet in length and bearing fifty-seven blooms. Amongst others in flower very conspicuous were several plants of the now-seldom-seen *C. rosea*, or, as it is perhaps better known, *Limatodes rosea*. This is a most useful plant for decoration, the flowers of a beautiful shade of rose, from light to dark.

**Zygopetalum erinitum.**—This beautiful plant is now flowering well in the collection of Mr. H. Grinling, of Harrow Weald House. By some authorities it is considered a distinct species, whilst others place it as a variety of the popular *Z. Maekayi*, which it very much resembles both in growth and in the shape and colour of its blooms, the latter being usually somewhat smaller. The pseudo-bulbs are about 18 inches in length, and the scape which springs from the base of the bulbs often carries seven or eight fine flowers. These individually are about 3 inches across, the sepals and petals greenish-yellow, blotched with purplish-brown, whilst the white lip is beautifully veined with bright blue, these veins being fringed with short hairs. This, however, is the best variety, for there appears to be another form in cultivation which is very similar in every respect, but having the veining on the lip of a rosy-pink colour, which is neither so attractive nor beautiful as in the preceding. This fine plant is a native of Brazil, where it grows abundantly on the Organ Mountains. It first made its appearance in this country just sixty years ago, and should find a place in every collection, however small, on account of its easy cultivation, for not only is it one of the most easily managed Orchids, but the same must be said of the majority of sorts in this genus. The plants should be potted in fibrous peat and Sphagnum Moss, and a little silver sand added, with good drainage, for they enjoy a plentiful supply of water, especially during the summer

months. This kind enjoys being repotted annually. This should be done when fresh roots are commencing to grow. The Zygopetalums succeed well with the Cattleyas, and during the summer require to be shaded from the sun.—W. H. G.

#### SHORT NOTES.—ORCHIDS.

**Odontoglossum Cervantesi roseum.**—I recently noticed a remarkably highly-coloured form of this fine plant carrying several fine racemes of flowers. These individually were large and of good substance, with the usual curious markings of rich brown at the base of each segment, the whole suffused with deep rose. It is a very fine variety.—W.

**Maxillaria venusta.**—This is a very showy species, producing fine blooms, quite 6 inches across the lower sepals. The sepals are spreading, pure white, the petals also white, but much smaller and standing out almost parallel with the clavate column; the lip is short and fleshy in texture and of a brownish yellow on the upper surface. This Maxillaria is a native of Venezuela and New Grenada, and is a striking object when in flower.—W.

### GARDEN FLORA.

#### PLATE 1001.

##### AUTUMN OR WINTER DAFFODILS.

(WITH A COLOURED PLATE OF STERNBERGIA MACRANTHA.\*)

THE accompanying plate represents a class of bulbs to which far too little attention is given,

A clump of the Winter Daffodil (*Sternbergia lutea*).

and for this lack of interest the uncertain character of our late autumn and winter months is, no doubt, accountable. The yellow Crocuses help to carry us through the dull months, but the flowers of the Sternbergias, being of much firmer texture, are able to withstand a far greater amount of bad weather than those of the Crocuses, and are thus better adapted for our climate. One great source of failure with Sternbergias and many others of a like nature is the fact of their being frequently grown in such positions as to necessitate their being disturbed at the wrong time or before growth has fully developed. In one or two gardens I have seen these grown in flower borders and lifted

\* Drawn for THE GARDEN by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by Guillaume Severeys.

early to make room for bedding plants, and the wonder was that they never flowered. What these Sternbergias want chiefly is, thorough ripening in summer and a slight protection, such as dry litter, &c., during the winter. It will depend upon the nature of the soil, as well as the position in which the bulbs are grown, whether they will have to be lifted or not. If the soil is heavy and clayey, the best plan will be to lift the bulbs when the leaves have died down and let them ripen, in the same way as those of *Anemone fulgens*, &c. In light sandy soil and fully exposed to the sun, the bulbs will in all probability get the necessary ripening without being lifted, and in this case the only plan will be to leave them undisturbed until they attain flowering size.

The species, as described and arranged by Mr. Baker, are as follows:—

**S. COLCHICIFLORA.**—This is one of the old garden plants, having been cultivated by Clusius and Parkinson—by the former as *Narcissus persicus*, and by the latter under the name of the lesser autumn or winter Daffodil (*Narcissus autumnalis minor*). It is described as possessing the most delicious fragrance, and perfuming, with its Jessamine-scented flowers, the fields of the Crimea, especially about the Bosphorus. The leaves are narrow, linear, and produced along with the fruit in spring. The flowers appear in autumn at about the same time as those of *S. lutea*, perianth segments nearly 1½ inches long, and of a very pleasing pale or sulphur-yellow. It is found on dry exposed positions on the Caucasian Mountains, Crimea, &c., and is perfectly hardy in this country, treated in the same way as *S. lutea*. *S. dalmatica* and *S. pulchella* are varieties.

**S. CLUSIANA** (Ker, not Boissier).—*Narcissus persicus* (Clusius), *Amaryllis citrina*, *A. colchiciflora*, *S. atnensis*, and *S. Schuberti* are synonyms.

**S. FISCHERIANA** is nearly allied, and has the habit of *S. lutea*, from which it differs chiefly in flowering in spring instead of autumn, and by its stalked ovary and capsule. It is a native of the Caucasus, perfectly hardy in this country, and is the *Oporanthus Fischerianus* of Herbert's "*Amaryllidaceae*," 46.

**S. LUTEA.**—This is the great autumn or winter Daffodil (*Narcissus autumnalis major*) of Parkinson. The absence of seed on this bulb in a cultivated state is rather remarkable, seeing how plentiful it is and also how profusely it flowers in many parts of the country. The only seed I have seen has been obtained from dried specimens collected in the neighbourhood of Palestine. The same experience has been recorded by Dean Herbert in his "*Amaryllidaceae*."

My experience leads me to the conclusion that the bulbs must be large before they will flower freely, and, as is usually the case with imported bulbs, they are generally small and will take a year or two to attain flowering size. *S. lutea* has five or six leaves, each about half an inch broad, about a foot long, and produced at the same time as the flowers in autumn and winter. It is the *Amaryllis lutea* of the *Botanical Magazine* (290), *Oporanthus luteus* of Herbert's "*Amaryllidaceae*," and is supposed by some writers to be the Lily of Scripture, as it grows abundantly in the vales around Palestine, &c.

**S. ANGUSTIFOLIA** appears to be merely a narrow-leaved form of *S. lutea*. It is very free-flowering, and grows rather more freely than *S. lutea*.

**S. GRECA**, from the mountains of Greece, has very narrow leaves and broad perianth segments.

*S. SICULA* is a form with narrower leaves and segments than the type, while the Cretan variety has considerably larger flowers.

*S. MACRANTHA*.—This, introduced by Mr. Whittall from the mountains of Smyrna, is a really handsome species, as will be seen by the coloured plate. The leaves are blunt and slightly glaucous, about an inch broad when fully developed about midsummer, flowers bright yellow, produced in autumn. A native of Palestine, Syria, Western Persia, Asia Minor, &c.

*Botanic Gardens, Glasgow.*

## THE WEEK'S WORK.

### FRUIT HOUSES.

**BANANAS, HOME-GROWN.**—These are now largely grown in private gardens for dessert, and those who have a liking for them well know the value of those home grown. Now is a good time to make a start where it is intended to take up their culture, and many who possess modern houses can grow the Cavendish variety, as this kind is dwarf and fruits freely and quickly. I saw a house containing six plants planted some eighteen months ago. These had borne on an average 67 lbs. weight each, and in a period of fifteen months. The value of *M. Cavendish* is its dwarf compact habit, compared with that of other kinds. The plants range from 6 feet to 7 feet high and they require far less heat than others. Many can find space for this plant who have only medium-sized houses; indeed, in such houses better fruits can be had than in those where the plants are a long way from the glass. I consider *M. paradisiaca* the best, but few can grow it, as it requires so much room. It produces a small fruit in comparison to its size and immense leaves. *M. sapientum* is nearly as large, but bears a much larger bunch. In my opinion it is not superior in quality to the first-named dwarf useful variety, as it takes longer to make a plant and the fruits are longer in ripening when formed. There are various forms of this variety, some nearly green, others with dark or purple fruits. Most of them attain a height of 20 feet and have leaves each 10 feet to 12 feet long. These three varieties are about the best for house culture if the fruits are grown for dessert.

**CULTURE OF THE PLANTS AT STARTING.**—I have advised a suitable house for the plants, but it must not be thought that the plants cannot be grown in pots, tubs or in a restricted area, as in the latter they do well. To get rapid growth it is essential to grow in rich soil, and maintain a high temperature and a humid atmosphere during growth. The plants fruit freely with only top-heat, but are much longer about. In making a bed for the roots give abundant drainage and 2 feet to 2½ feet of clear soil, and if possible restrict each plant to a certain space. The plants should face south, so that they can get the full sun most of the day in a span-roofed house. Bananas like a strong loamy soil, with manure (well decayed) and such aids as bone-meal or other fertiliser. As they require plenty of water during growth, it is well to add broken charcoal to the soil to keep it sweet. Plant firmly and water sparingly at the start. When the plants are purchased one cannot obtain them so large as one would like. It is not well to plant weak suckers with only a few roots. I would prefer to pot up the suckers till they have filled 8-inch or 10-inch pots, and plant out in April or May. If potted up now and plunged in a warm bed, good plants will be had in from six weeks to eight weeks. Such plants will start well when planted out and fruit freely next spring; whereas if planted out in a small state, especially when there is no bottom-heat, they present a miserable appearance all the year, and in some cases do not fruit at all. There is much gained by growing as advised, as the plants are in condition to rest during November and December. Having made

a strong growth, they may be kept cooler and drier at the roots during the time named, and will then throw up fruits during the spring, such fruits being appreciated in the late summer or autumn. I have advised a restricted root space. This is to hasten ripening or formation of fruit, as when there is a too free root-run fruits are not so reliable. A bed 2 feet to 3 feet deep and 3 feet to 4 feet square will grow good fruits if room is not plentiful. The temperature at the start should be 70° to 80° by day, 65° to 70° by night, with an unlimited supply of atmospheric moisture. Fruiting in pots is very much like that advised above. Now is a good time to make a start. Give bottom-heat at first, and do not over-pot. I prefer to get the plants into 10-inch pots before shifting them into their fruiting ones.

**HARDY FRUITS.**—With protracted frost in most parts of the country, the work in this department has not made much progress. With open weather there should be no delay, and the pruning of most kinds of fruit trees should be finished, as many of the earlier varieties will soon be on the move. The work in the orchard should not now be neglected. Any old standard trees that have been neglected of late years may with advantage receive attention in the way of pruning, removal of cross wood or barren growths thus admitting light and air. I do not advise severe pruning or topping of branches as is at times practised, but much may be done by timely thinning and admission of more sun and light. The training of all wall fruits, with the exception of Peaches, Nectarines, and Figs, should be finished. I am glad to see the trees have benefited by the severe weather, as the buds are not so prominent as they were last season early in December. In the case of newly planted trees it is not advisable to prune till late in March or early April, merely cutting or shortening long shoots. Many good fruit growers do not advise even this the first season, but much depends on the vigour of the trees when planted and soil and situation. The planting of all fruit trees should be brought to a close as early in March as possible, as in light, gravelly soils they suffer in a hot, dry summer. After planting, a good mulch of decayed manure with a little rougher material on the surface should be given. Staking newly-planted trees should not be neglected, giving them ample space to grow. From Fig trees on walls that have been very thickly covered, a small portion should be removed as the season advances. Apricot trees on south-west aspects promise well, and should get protection ere long. I have found a simple and efficient protection is to use stout Bamboo rods secured to the wall at the top and lightly pushed into the soil at the base, covering with a double thickness of inch-mesh net. This admits light and answers thoroughly.

**STRAWBERRIES.**—The older plantations will repay surface cleansing and removal of weeds and old decayed leaves, mulching with decayed manures. In light soils this dressing is important, as the roots get bare on the surface and the new material gives these a start and builds up the plants. In gardens where the soil is light and manure none too plentiful, I have used such aids as old beds of Melon or Cucumber pits with a good portion of heavy soil. Previous to placing the manures on the surface do not fork or dig the surface, merely hoe lightly and remove weeds. The frost will have lifted the young plants which were planted last August or September. These should be trodden in firmly before hoeing between the rows. When the weather is open is a suitable time to apply liberal dressings of soot between the rows.

**BUSH FRUITS.**—The pruning of Currants and Gooseberries should now be finished by this date; the pruning of the latter is often deferred till the last moment on account of the birds. I always prune early and net over, as otherwise it is impossible to get a crop. In pruning, well thin out the head to facilitate gathering the fruit, cutting away the growth lying on the soil and removing all suckers. The trees well repay a good surface dressing of rich manures. Should the cater-

pillar have been troublesome, it is well to draw away the surface soil, wheeling it away and giving a good dressing of fresh lime before giving new soil. If nets are not available it is well to syringe the trees after pruning with quassia water, and then dust over whilst damp with quicklime. It is necessary to dress Currants also, as the birds soon spoil a quarter if not checked. The same remarks apply to Currants as regards manure at the roots in the form of surface dressings. Young trees that are being grown now to form new plantations should be replanted, as by change of soil better growth is secured, and crowding in a young state will spoil the shape of the trees.

G. WYTHES.

### THE KITCHEN GARDEN.

**TOMATOES.**—Where winter fruiting plants have plenty of room to extend, the latest formed growth will now be furnished with a good percentage of blooms. These if carefully fertilised will set with more certainty than the December and January formed flowers. Fertilise daily at noon, withholding floor sprinklings until the afternoon, as at this date Tomatoes are benefited rather than otherwise by a comparatively dry atmosphere, a more wiry and fertile growth being thereby encouraged. If the plants are not standing too closely together, a few shoots may be trained up from the bottom, say one on each side, to produce fruit later on and thus keep up a succession. Remove at once all side laterals and top-dress as soon as new white feeders appear on the surface, adding or withholding a fertiliser, according to the strength of the plants. During the continuance of bad weather, 60° to 62° as a night temperature will be the best for the plants, 65° being allowed when mild and open. A little air must be given on all sunny days, but draughts strictly guarded against, as the tissues of the young leaves are very tender. Young plants raised from seed sown in January will now be sufficiently advanced to need support. Neat sticks should be used and the ligatures left rather slack, as Tomato stems swell very rapidly. Arrange the plants close to the glass and water very carefully, especially where heat is deficient, or the "yellows" may set in and ruin the batch. Upon no account should the syringe be used overhead, and a dry atmosphere at nightfall should be maintained till the weather gets warmer.

**VEGETABLES IN FRAMES.**—Early Potatoes and Currants being brought on by means of hotbeds have had an unfavourable time lately. With from 16 to 20° of frost and cutting winds for many nights in succession, not only double mats, but thick coverings of long litter or Bracken have been necessary to keep the interior of the frames in anything like a comfortable, not to say forcing condition. As much outdoor labour has been impracticable, there has been ample opportunity for adding fresh heating material to the surface of the linings, this being elevated, so as to come on a level with the lights, and well trodden. Extra coverings in case of continued frost must also be given to all tender crops growing in frames, hand-lights containing Cauliflowers and ridges of late Celery, as it is now certain that great breadths of greens of all descriptions, including Brussels Sprouts, Cabbage sprouts, late spring Broccoli, and even some of the Kales have already succumbed to the intense frost, and that the demand for young transplanting stuff will be greater this spring than usual. Lettuces at the foot of south walls, which are safe in any ordinary winter, must be covered with some littery material where the wall has kept the snow from falling on the plants.

**EARLY COS LETTUCE.**—Where much salad is in demand early in the season and a good quantity of plants of the old Brown Cos were framed in October, with a view to removal to the garden during February and March, it is a good plan in such seasons as the present to thin out the plants, leaving every second one to develop. If the frames are wanted for other things, they may be carefully

lifted with a good ball of soil and transplanted into rough, home-made frames, and protected at night for a time. A scarcity is thus avoided. Lettuce quickly respond to a moderate dressing of any safe artificial manure sprinkled on the surface and raked in. All batches taken from frames or pits and planted in the open ground will be the better for a screen of Yew boughs for a fortnight or three weeks, even when under a south wall. Mildew and damp are often very troublesome after a thaw, to counteract which a free use should be made of wood ashes, and the lights tilted instead of being drawn off in rainy weather. Where Hardy Hammersmith or All the Year Round Cabbage Lettuce were given frame protection these will now be invaluable, being full-hearted.

**AUTUMN GIANT CATTIFLOWER.**—It does not appear to be generally known that Autumn Giant if sown in autumn with Early London and Walcheren, protected through the winter, and put out in March, will do equally as well as any other sort, and afford fine heads from the middle to the end of July. Where this is not practised, seed may now be sown of both Autumn Giant and Self-protecting Autumn Broccoli. The former will then be fit for use immediately after the summer batches of Pearl and Walcheren are over and before the open-air March-sown batches of Autumn Giant are fit for use. Boxes answer well for sowing the seed in, and an intermediate temperature best favours germination. As soon as the seedlings are fit for handling, thin out freely, as crowded plants soon become affected by the disorder known as blackleg, which carries them off wholesale. At this stage a cool greenhouse with plenty of light and air suits them well until fit for pricking out into a frame or larger boxes. The Self-protecting Broccoli will heart in in October, and March sowings in the open will follow on through November and December.

**THE EARLIEST CELERY.**—The present is a good time to sow a pinch of Celery for a supply during September. A sufficiently large box should be used, so that the seedlings may not crowd each other after being thinned out, as a weakly constitution prone to bolting is engendered by too limited a space in infancy. Drain the boxes well and use light friable soil passed through a half-inch sieve, covering the seed very thinly with still finer material, and standing the boxes in a temperature of not more than 55; more than this is injurious. Immediately the first rough leaves are formed, prick out into larger boxes or on to a gentle warm bed if such can be afforded. Air can then be given as the plants increase in size and full exposure take place in April. Coddling is the greatest evil attending the raising of both early and later batches of Celery. For an early white variety Sandringham is still hard to beat, while Early Rose is a first rate red variety. Late Celery and that grown for flavouring may on the disappearance of frost be lifted and removed to a north aspect and carefully laid in, the ground being made firm round the roots as the work proceeds. It can then be covered in case of late frosts, and the ground turned up and got in readiness for other crops.

**ASPARAGUS BEDS.**—Many beds of this esteemed vegetable established on heavy soils and in low-lying districts cannot be surface-manured in autumn or early winter; indeed, on any but the lightest warmest soils and in elevated positions the system is not to be commended. The present month is the best time for the work. Fish manure is a capital stimulant laid on moderately, and will retain its strength better if slightly covered with light leafy refuse. I have seen very good results on very sandy soil from an application of pig manure in March, this being in a semi-decayed state and well saturated with the urine, the same being left on all the summer and the refuse raked off in autumn when the grass is cut down. If the summer should be dry this covering keeps the beds in a moist condition. Guano is a capital manure for heavy soils.

**HERB BEDS.**—Weather permitting, the herb order should be seen to and all exhausted stocks

renewed. Thyme, both the common and Lemon varieties, may be increased by division, as also Sage, Tarragon, and Mint; in fact, the majority of herbs are best treated in this way. Some good fresh soil and decayed manure should be mixed in if the old sites have to be used again, but fresh ground where at command is preferable. After planting, a mulch of rough leaf-mould or spent Mushroom manure will protect the newly-disturbed roots.

**FORWARDING EARLY CROPS.**—As, owing to the continued frosts, early sowings of Peas and Beans, also planting of first early varieties of Potatoes, are some time later than usual, those who do not, as a rule, forward these under glass will do well to do so this season. Peas sown in small pots or boxes and placed in a genial warmth soon germinate, as also do Broad Beans, and after due hardening are planted out with little labour; thus the unfavourable effects of a snowy February may be greatly modified. As digging and general garden work will be plentiful as soon as the ground can be trodden upon, manure wheeling should be completed with all speed, as even if snow lies on the ground, a passage can be cut with shovels and the manure tipped into this.

**SEED UPBOARD.**—As soon as the new seeds come to hand a thorough cleansing should be given to the seed cupboard, each new package being laid most conveniently according to the time it will be wanted for sowing. Do not rely on old seed.

J. CRAWFORD.

## GARDEN SKETCHES.

### CHAPTER IX.

“Season of mist and mellow fruitfulness,  
Close bosom-friend of the maturing sun.”

KEATS.

**AUGUST 3.**—This evening falls the touch of autumn over hill and dale. The day has been one of dark clouds and showers. Now, towards sunset, the sky is clear, and an amber light falls aslant the valley. A wandering breeze ripples gently across the ripening corn and silvers the bending Willows as they yield their slender leaves to be turned aside. A purple glow on the hill-tops shows the heather in bloom, and lengthened shadows fall from the scattered woodland. In the distance the sea is deeply blue like a sapphire, flecked here and there with a white sail moving onward, while passing down to the shore come the gently flying seagulls with arched wings gleaming white against the deepening shadows.

The Rowan tree with its clustered berries of coral-red proclaims the harvest of the blackbirds, and the Japanese Roses are covered with crimson and orange fruit. A little while ago the white variety was very lovely, the milk-white blossoms and glowing berries mingling together, for the hips, like miniature Mandarin Oranges, were ripe much earlier than usual this season. These Japan Roses (*Rosa rugosa*) can be propagated by seed sown when ripe, and though there is a few years' waiting to be gone through ere they blossom, one has the reward of different tints among the flowers, and any one specially beautiful can be increased by suckers, which healthy plants send up freely. A sunny position seems needed for luxuriant fruiting, but the roots appear to enjoy a free and moist soil. Where there is room for hedges of these shining-leaved Roses they would be very beautiful, and their passing away in robes of gold and crimson would light up many a day in “chill October.” Tall Gladioli that have caught the western sun in the flower border rise like a flame from the earth, while the pure white blossoms of *Anemone japonica* are fresh and cool as they ramble through a shadier spot. This *Anemone* resents being disturbed, but as

the finest flowers are from fresh offsets or runners, new plantations require to be made from time to time, the dense and older portions being thrown away. It does not seem particular as to soil or position, but left to colonise itself under the light shadow of trees is perhaps its happiest home, for there in the dusky setting the blossoms gleam like wandering stars.

In the rock garden a group of *Hydrangea paniculata* has bending branches of creamy plumes, seen against the deep crimson of *Montbretias* clustered beside it. An undergrowth of some soft-tinted *Viola* would be lovely beneath these drooping panicles of bloom. This *Hydrangea* requires severe cutting back each spring to make it blossom freely. The Plume Poppy (*Boconia cordata*), with its erect growth, makes a fine break among low-growing shrubs; its glaucous leaves and wands of gold-brown buds, expanding into a white misty bloom, remain in perfection for a length of time, and they are exquisite arranged in a Japanese jar of red, white and gold. In a rich border it becomes too coarse and rampant, but a more repressed growth in a poorer soil quite alters its character to delicate grace. The blooms of *Eurothera macrocarpa* are flowing over a rocky ledge. The charm of these flowers is their little spotted tiger skins in which the buds are wrapped, and which they toss to one side as they expand; the blossoms also change to apricot hue when fading away. *Acena microphylla* is quite a sheet of bloom, with spiny globes of rose-pink clustered together. *Linaria alpina* is a rock gem, with its lovely purple flowers and stain of orange at the lip, and leafage into which the purple hue seems to have flowed. It seeds so freely around, that young plants are to be found far and near, the cinder path being specially to their taste. A mass of the white *Campanula pumila* falling over a rocky ledge has been a miniature cascade of blossom, with its low, dense growing bells tumbling over the stones.

**AUGUST 20.**—A few misty mornings have brought us that most exquisite sight, the spiders' webs bedewed with moisture! From every Lily's petal, from every Rose tree's branch, from every stem that holds a bud or blossom, are hung these gossamer webs. It is a sudden revelation. Where nothing seemed before, now we behold these intangible veils suspended from leaf to leaf, from flower to flower, and strung on every thread with infinitesimal pearls of moisture. So strongly do they show on the dark *Berberis* trees, that they suggest the idea of fairies' linen hung out to dry, linen of such gossamer texture as only spirits would don. But no sooner have the sun's rays dispersed the mist than the vision of beauty is gone.

Warm days have come once more after wind and rain. The grain has been harvested, and golden sheaves are laid together in the distant fields. The late Clover is full of murmuring bees and scents the air, and fields from which the hay has been gathered early show like emeralds amid the golden setting of ripened corn. The autumn Lilies are with us now. *Lilium tigrinum* makes a grand clump in the border, slowly opening and lasting from week to week in beauty, its rich warm colour showing up well against the dark evergreen background. It passes through storm and rain quite fearlessly, and asks but little more than a good top-dressing in November. *Lilium speciosum*, pink and white, is lovely springing up among the China Roses.

The Tritomas, with their torches all alight, have sent a glow throughout the garden. John Benary, a variety entirely crimson, seems almost to burn with a ruby light, so intense is its

crimson glow. These Tritomas are splendid for grouping where they can be seen against the sea or far-off hills. In a more limited space they are very fine against the fresh growth of young Fir trees with their bluish-grey hue, or in front of the climbing Virginian Vine, as it changes in tint to deep maroon. The best time for moving or division of these plants is during the month of April. They will then start quickly into growth, and if given an open sunny position and good rich soil, will rapidly become strong clumps. The earliest Starworts are now in bloom. How completely the beauty of these Western Daisies is lost when they are tied together in a bundle and fastened to a stake, all the grace of their stems destroyed and no possibility of blossoms developing but at the summit. How charming would an alley be of the taller kinds left to themselves to toss and fall and mingle at their own sweet will—a delicious boundary of soft and tender colouring such as all our efforts could not produce. Where growing in a border, a few slight leafless branches stuck among them will generally afford sufficient support, and when a spray falls down and flowers in that position, how beautiful it is! One of the most graceful Michaelmas Daisies is *Aster elegans*, the entire length of the stems being covered with sprays of pale mauve flowrets, so that the whole plant has the appearance of a haze of blossom. As these Starworts rapidly exhaust the soil, constant root-division is needful, the ground being well enriched when replanting. As the plants grow it is well in the early stage to thin out some of the stems, as the remainder have then room to spread, and a few stems seen in perfection of leaf and blossom in their entire length are far better than a whole mass smothering each other and with the base of the stems sere and yellow. Position does not seem of as much consequence to the Starworts as a deep and fertile root-run. *Rudbeckia Newmanii* is luxuriating in the late moisture; the rich orange-yellow discs with dark velvety centres make a fine flower group, especially just beneath the deep crimson leaves of the Virginian Creeper that is climbing over the garden wall. A handful of these rich sprays and leaves with the flowers of the *Rudbeckia* are lovely together. A little further off against the wall is a bush of *Crategus Pyracantha*, with its brilliant scarlet fruitage. A brick wall clothed with these glowing berries that seem to set it all afire is a sight not easily forgotten, while in spring the white lace-work of blossoms is almost as fair to see, and the deep green foliage that bears rough storm so bravely is cheerful all the winter through.

Very lovely are the *Cyclamens* now appearing over ground. One always finds them at first in bloom with a little start of rapture. They seem to have arisen so suddenly where nothing was before, and where the corns are large so as to produce hundreds of blossoms, their beauty is prolonged considerably; then as the flowers cease, uprise the finely mottled leaves to remain in beauty until the burning sun of another year's July. Seen to-day with white and rose-pink blossoms bordering the bed of Ivy-leaved Geraniums, they are charming, but still more so as they nestle in groups under the Deodar on the lawn, where at one side a few low branches were crushed to death by a tree since then removed.

The Sachalien Knot Grass (*Polygonum sachalinense*), in flower at present, has been hitherto known to us for its graceful flowering wands, beloved of the bees, but in this season of prolonged drought its claims as a forage plant have been brought forward prominently through the writings of M. Doumet-Adanson and by expe-

riments carried out in different parts of France with success. It has been calculated that grown for green fodder the yield would be per acre of from 60 tons to 120 tons. The vigour of this plant is irrepressible. Even in the hard-trodden pathway the young growths push upward, and for many yards around fresh rhizomes will press along underground and spring up in the most unexpected places. To ensure a beautiful group of this Knot Grass, the young growths must be thinned out when they appear in spring so as to allow of those left attaining to their full size. The paniced clusters of greenish white blossoms slightly drooping from the red leaf stems clothe the plant in early autumn, while later on the change of leaf robes it in amber. Even when the foliage falls its beauty is not yet over, for the tall wands of purple-red are still handsome and need not be cut down till the succeeding spring. This *Polygonum* was discovered by a Russian botanist named Maximowicz when exploring the island of Sachalien, which lies in the Sea of Okhotsk, between Siberia and Japan, from whence it was first brought to Russia about the year 1869. It is readily increased by root division in spring or autumn, and once planted no further care is necessary save to chop away the spreading rhizomes, as otherwise they would take entire possession of whatever spot of soil they may be in.

*Tropeolum speciosum* is in its pretty seed stage, those clustered seed-vessels of gem-like blue that make the plant still interesting when the flame of blossom has swept by. This *Tropeolum* is in full sunshine, but its root is safe and cool beneath, shaded by the thick branching *Cotoneaster* that climbs by the entrance steps of the dwelling-house. Through these branches the *Tropeolum* creeps in spring-time, and once free, flings its delicate stems across the deep green shrub, resting on which it flowers contentedly all through the summer days.

Since rain has fallen the Acers have made rapid growth, and when the sunbeams pass through the young leafage it shines with a burning light that is quite indescribable. During the dry weather they scarcely made any visible growth, but now the fresh shoots are most brilliant. Although these trees from Japan seem to revel in the sunshine, they also need much root moisture.

A bed has just been prepared in a sheltered spot for cuttings of all kinds, Pansies and hardy plants, and all sorts of flowering shrubs. Even if not needed for oneself, it is well to have an overflow for the friends that visit one's garden, and to be handed a plant with a root appears always a much greater gift than when one is merely given a slip or cutting. The giving away of plants seems ever to increase one's own. The plant that is divided appears to flourish better. The half that is left becomes more vigorous from having greater space and ceasing to be exhausted in its search for nourishment, so that giving is gain in the garden as well as elsewhere through life, and no lesson do the flowers more strongly teach us than that of "freely ye have received, freely give." Cuttings put in now root freely while the ground is still warm, and are ready to plant out in October or in the following spring.

In the rock garden *Sedum spectabile* has taken the place of the *Eryngium* now past in drawing to it a crowd of red admiral butterflies and large bumble bees, that rest intoxicated on its great bosses of rose-pink bloom. The charm of this *Sedum* lies in its thus gathering to itself the beautiful winged insect life around, which makes it so conspicuous in the sunny

autumn mornings. *Gazania splendens* is too seldom seen in our gardens, and yet it is a gorgeous blossom with rays of ruddy gold set in leaves of silvered lining. Sunshine it must have, as only then will it expand and show the inner circle of dark Argos eyes. Save in warm localities, it will not survive the winter, but cuttings taken now will form good plants for the following year. L. A. L.

(To be continued.)

## STOVE AND GREENHOUSE.

### CAMELLIAS UNHEALTHY.

B. C. MANSFIELD'S second letter explains what we surmised, that the border is at fault. Opposite extremes will both act injuriously to the plants. In your case it does not by your own showing proceed from dryness at the roots. The border is evidently in a bad state, if border it can be called. This is affecting the roots—the fact of the soil remaining "very wet and pasty for a long time after watering" would account for this. The way in which the plants were planted out in square holes was a mistake. They have never taken kindly to the soil outside of these holes, hence the roots are confined to a limited space—far worse than if starved at the roots in pots or tubs. The attempt to force them into flower so as to have a good quantity of bloom at Christmas cannot but end in failure whilst the present condition of things exists at the roots. In forcing *Camellias* the treatment should vary from what is accepted as the usual mode of procedure in forcing. To force the plants to expand their flowers is not congenial to them. What should be done is to hasten the growth as soon as it commences after flowering, continuing to give warmth until the new shoots and leaves are quite hardened. To give an example of flowering *Camellias* early, I will quote an instance which will give an idea of the correct treatment. The *Camellias* in question were planted out against the back wall of an early Peach house. Here they made and finished or ripened their growths early, flowering before and during Christmas-time whilst the house was still cool or before any heat was applied for the Peaches themselves. This illustrates the plan to adopt in as clear a manner as possible. The plants in question may make a fairly good growth. *Camellias* will do this and yet fail to flower satisfactorily. The best remedy will be to lift the plants carefully, saving all the healthy roots as far as possible, and then remove all of the soil in which they were planted, as well as that surrounding the holes. Then drain the border with broken rubble, old brick-bats, clinkers or potsherds, as the case may be, providing also by means of pipes an escape for the water. On the drainage place a layer of the coarsest peat and loam and make the border up with the same kind of soils in about equal parts with sand or road scrapings, but much rougher than in pot plants. Around the roots some finer soil may be needed, finishing off by making all firm. Then with one good watering at once and frequent syringings afterwards the plants should soon start into fresh growth.

SOUTHON.

*Luculia gratissima*.—This greenhouse shrub will grow freely enough in almost any situation provided the soil is free and the drainage good, but to get it to flower it must have a maximum amount of sun. Where this is deficient growth may be rampant, but the bloom trusses never develop. A sunny greenhouse or conservatory freely aired throughout the summer suits the plants well, enabling the growth to mature and the trusses to open in autumn. A compost consisting of good fibrous peat or three parts peat to one of loam with some opening material added suits the plants well, and when in full growth plenty of water must be given with a stimulant once a week.—J. C.

SIMPLER FLOWER GARDEN PLANS AND BEDS.

WHAT a vision opens out to anyone who really considers the design of the flower garden when he thinks of the curiosities and vexations in forms of beds in almost every land where a flower garden exists! The unfortunate gardener is the heir—to his great misfortune—of much useless complexity and frivolous design, born of applying conventional design to the ground. These designs come to us from a remote epoch, and the designing of gardens being from very early times in the hands of "artists" and decorators, the garden was subjected to their will, and

smaller, soon got out of order, and after a few years the whole thing was painful to see. And good gardeners were losing their time trying to plant paltry beds in almost every frivolous device known to the art of conventional "twirling."

Even where such extravagances as these were never attempted we see the evil of the same ideas, and in many gardens the idea of adapting the beds to the ground often never occurs to the designer. If the ground does not suit the plan, so much the worse for the ground and all who have to work on it.

By some people this objection on my part to conventional design is mistaken for an objection to formality itself altogether.

ground and to suit the ground. Our object should be to see the flowers and not the beds, so that while we have all the advantage of mass and depth of soil, and all the good a bed can give for convenience of working or excellence of growth, we take little pride in its form, and plant it so that we may see the picturesque effects of the plants and flowers and forget in the picture the form of the bed.

The relation of the beds to each other is worth considering, because, generally, it is much too complex and close and there is little freedom. Designs that were well enough for furniture or walls or panels applied to the garden gave us a new set of difficulties. Carried out in wood or in the carpet they answer

Garden at Golder's Hill. Flowers to left of house and towards margin of lawn, showing fine view over distant country. This plan (by R. Munnock) shows the error of supposing that the picturesque garden requires the walks to be "made crooked."

in our own days we have many times seen gardens laid out from the point of view of the "decorator," *i.e.*, beds without the slightest relation to garden use, difficult to plant and costly to keep in order. At South Kensington the elaborate tracery of sand and gravel, &c., there was attractive to some when first set out, but it soon turned to dust and ashes. It was, indeed, to a great extent formed of broken brickdust, in a vain attempt to get rid of the gardener and his flowers. The colours were supplied from the building sheds, where one saw boys pounding up bricks and slates, and little beds were made of silver sand, so that no gardener could disfigure them. The Box edgings margining beds a foot wide, or

Certainly there are bold spirits who do not mind putting their houses among rocks with the heather on them, but, generally speaking, we must cultivate a flower garden, and simplicity as to form of the beds should be the rule in it. There are many ways of growing flowers and all sorts of situations fit for them, but the flower garden itself near the house must often be laid out with regular beds, or else we cannot cultivate the flowers with convenience, or get about the ground with ease, and it is only a question of right and wrong formality. The beds in my own work are, as will be seen by the plans here given, as formal as any, but simpler and larger, and are made on the

their purpose, if we like them; but a flower bed is a thing for continual work, both in cultivating and in arranging and keeping it, and therefore it is best to see that we are not bothered by needless complexities in dealing with the ground. In these plans there is no difficulty of access, no small points to be cut in Grass or other material, no vexatious interruption to the workmen, but beds as airy and simple as possible and giving us much more room for flowers than beds of the ordinary type.

The three plans herewith given are those of wholly different kinds of gardens. The first, at Hampstead, is perhaps the most interesting example of a London garden for its disposition

as regards beauty, airiness, perfect repose, and fine distant view in which one can scarcely see a house, a result which it is novel to find so near London. This plan is also instructive in other ways—showing that where it is desirable to keep a lawn open and quiet for view, play or any other like reason, it is often easy to do this without interfering with the necessary flower gardening or any other charm of the place. The lawn is so open and airy, that any number of people may assemble on it without inconvenience or injury to anything. The lawn falls gently from the house, so that any walled terracing is needless, and, excepting a few steps for the convenience of level, little has been done in that direction. The plan also well disproves the

companions. At one end of the little garden is the gardener's house, and high walls surround the rest of the garden, so that there is shelter and every comfort for the plants. The garden is sensibly laid out to suit the ground, the plants—Roses and hardy flowers in great variety, a plan which admits of delightful effect in such walled gardens. Picturesque masses of Wistaria covered one side of the wall and part of the house, and the whole was a picture in the best sense. In such garden enclosures it would be difficult to find anything more delightful during more than half the year. A drawback in gardens of this sort in the old days was the absence of grouping or any attempt to hold "things together"—a fault which is easily got over. It is easy to

The third example consists of two flower gardens close to a Tudor house, with a garden door from the house into each. One being small (that on the south), it was thought better to devote it all to flowers and the necessary walks, all being done with a view to simplicity of culture and good effect of the plants. In the other garden, there being more space, the lawn is left open in the centre, while all round and convenient to the walk are simple, bold beds easy to deal with, and also spaced in a free and open way for people to get among them or about the lawn. The little south garden being much frequented in all weathers, and the paths among the beds rather small, it was thought best to pave them with old flagstones, and that has proved very satisfactory, because rolling and much weeding are thereby avoided and the walks are pleasant to walk or work on at all seasons. South of the house and these gardens there is an open, airy meadow lawn, the Grass of which is studded with many bulbs which flower in the spring. The vigorous kinds of spring bulbs are grown in great quantities in this field, and only the choicer and rarer early bulbs are put among the Roses and other flowers in the flower garden proper, which is mainly devoted to the more precious hardy flowers and to Tea Roses.

W. R.

THE ROCK GARDEN.

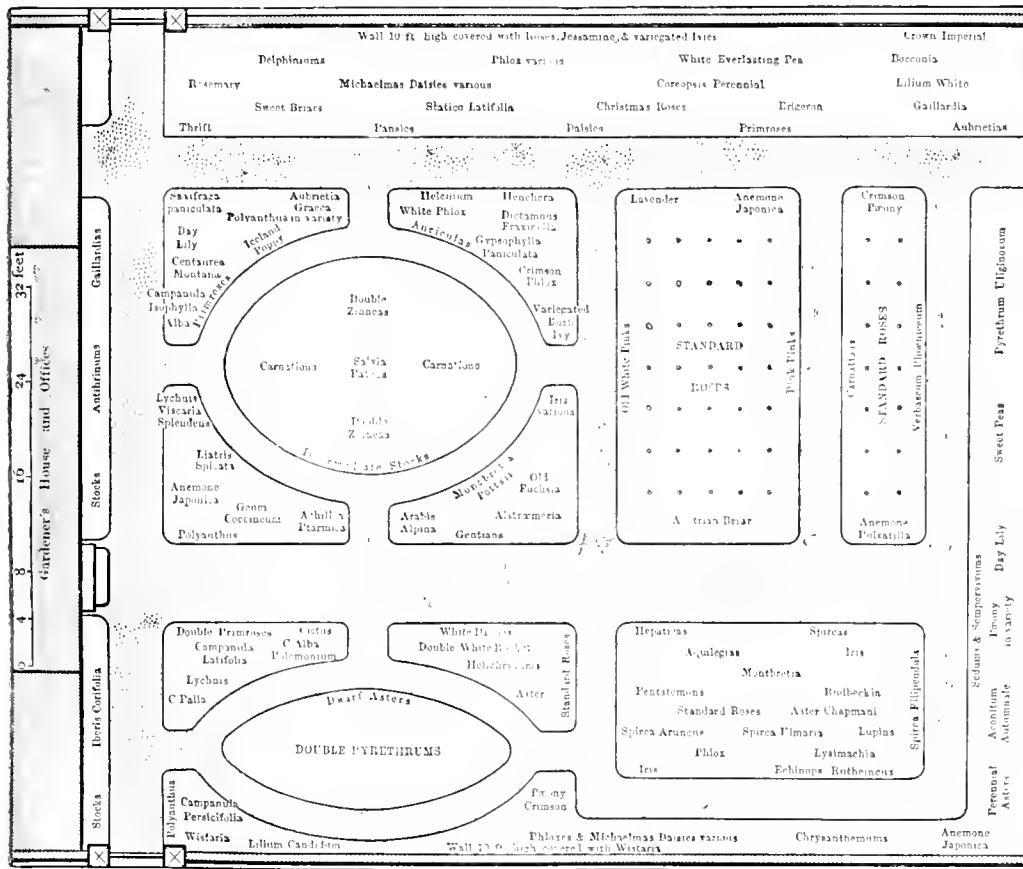

II.

JANUARY 26. — During the week just drawing to a close we have had a most miscellaneous assortment of weather samples in the west. It has been one continuous change from rain to sunshine, storm to calm, and frost to snow and sleet. In the rock garden, nevertheless, several fresh flowers have appeared, although we had 6" of frost and the ground is slightly sprinkled with snow. Three or four specimens of that charming rock plant *Morisia hypogea* have each of them several blooms expanded, though the plants were not sheltered or protected in the slightest degree. Nor is it the flowers alone that constitute so bright an ornament, but the glossy leaves greatly enhance the charm, and the effect of leaves and flowers peeping out from the snow at the present moment is particularly striking.\*

Slugs and snails seem to have acquired a special liking for *Morisia hypogea*, and I have known several instances where every vestige of the plant was to all appearance totally destroyed by their ravages. I found, however, that a fresh set of leaves would spring up from the roots even when the plant had long been considered as dead.

Another useful rock plant which has opened its flowers this week is *Arabis rosea*. This is at present about 4 inches to 6 inches high, and bears numerous rosy purple flowers. It is not so compact in its habit of growth as *Iberis stylosa*, which I mentioned last week, but spreads more after the style of *Arabis alba*.

\* Since writing the above the thermometer has fallen in Exeter to 20° of frost, and all alpine are buried in snow, which is frozen hard on the surface.

Sheltered little garden in front of gardener's house at Uffington House, Stamford, with simple beds of Roses and hardy flowers, the space enclosed in walls.

thoughtless assertion of certain writers that landscape gardeners always twist their walks about.\* It is seen here that nothing of the kind is done in this most picturesque garden. The flower beds are rather few and bold, and made large for the sake of ease of cultivation and breadth of effect.

The next plan is that of the gardener's house at Uffington, near Stamford, which I had the pleasure of seeing last autumn; it is an example of the older-fashioned garden not uncommon before nearly all gardens were cleared for the sake of the Perilla and its few

avoid scattering things one likes all over the beds at equal distances, and, without "squaring" them in any stupid way, to keep them rather more together in natural groups and colonies, where they are many times more effective to the eye, and in winter it is much easier to remember where they are. In this way, too, it is easy to give a somewhat distinct look to each part of the garden. Box edgings may be used in such a garden, and where they thrive and are well kept they are very pretty in effect, but always distinctly inferior to a stone edging because more troublesome, and also because the plants cannot fall over them as they can a rough edging of natural stone—the best of all edgings.

\* "Because Nature is assumed never to show straight lines, all paths are to be made crooked."—*The Formal Garden*.

which it somewhat resembles in general outline, but its leaves are of a brighter green and more deeply notched at the margin. The plant is probably too robust in its growth to associate with the dwarfest forms of alpine plants, but for a rocky border devoted to larger plants it should be just the thing, especially where earliness of flowering is a consideration.

Though the ground is covered with snow, an hour's sunshine has removed the snow from the plants themselves, and I noticed a particularly striking effect of a rock covered with *Sempervivum triste*. The stones and soil are white with snow, while the bold rosettes of this *Sempervivum*, with their dark bronzy red colour, stand out in bold relief, forming a delightful contrast. Particularly handsome, too, is at present the foliage of *Meeconopsis Wallichii*. It has a peculiarly shaggy appearance, owing to

Saxifrages I would mention *Saxifraga lantoskana superba* and *S. paradoxa* as being particularly ornamental at this season. *Saxifraga capillaris* also is very effective; its leaves are a bright green and very much resemble *Soldanella*.

Of *Androsace*, the Himalayan kinds (*A. lanuginosa* and *A. sarmentosa*) are not ornamental at this time of the year, and present an appearance so bare and shrivelled, that those unacquainted with the nature of these plants might consider them to be in a dying condition, but as soon as the warmer weather sets in they will quickly change their appearance. Very much more ornamental at this season, even though they are not yet blooming, are such compact growing gems as *Androsace helvetica*, *A. cylindrica*, *A. pyrenaica*, and *A. obtusifolia*. As these varieties are generally found growing side-

leaves, and is here at least quite hardy, the dark-leaved *Leiophyllum buxifolium* and the glaucous-leaved *Mesembryanthemum uncinatum*.

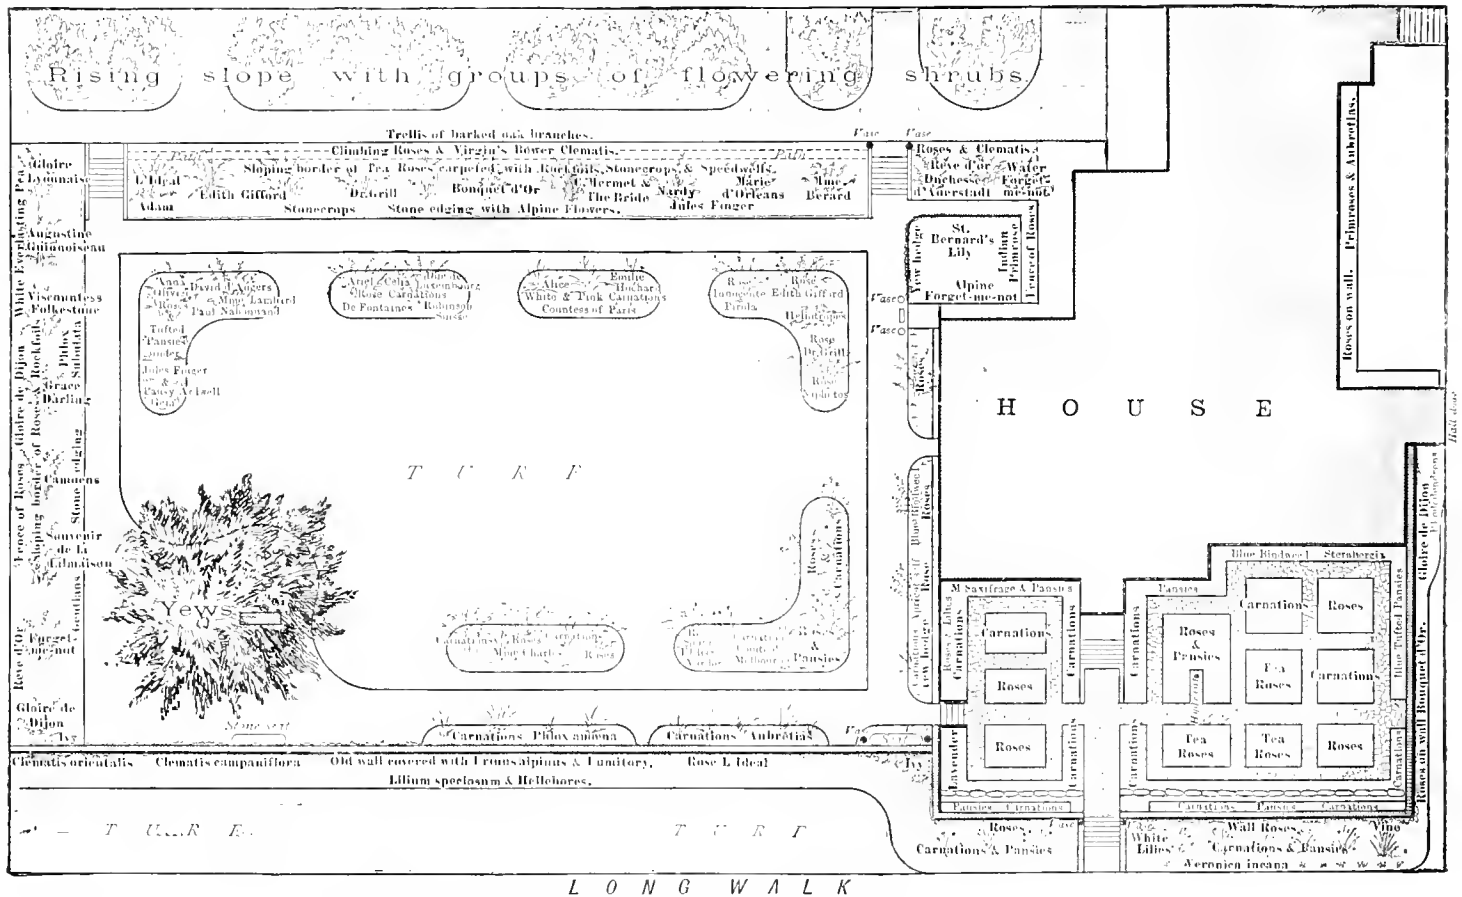

F. W. MEYER.

(To be continued.)

## CHRYSANTHEMUMS.

### BROAD-PETALLED JAPANESE CHRYSANTHEMUMS.

THE additions to this type of the Chrysanthemum are becoming numerous, and we are accustomed to read of new varieties like *E. Molyneux* or *Mrs. C. W. Wheeler*. They have wide, thick, leathery florets of varying length and are

Garden in Sussex designed to secure easy cultivation and good effect, and planted with choicest hardy flowers, as one way out of the "bedding" system.

the numerous long yellow hairs covering the stems of its leaves.

In my last contribution I mentioned several rock plants that might be used for winter effects on account of their handsome foliage, and to these I would like to add a few not previously mentioned. *Saxifraga cesia* is one of the minutest gems, and, like most Rockfoils of the encrusted section, its foliage appears even more white and silvery during winter than in the summer months, when new growth is being made. *S. cesia* planted sideways against a dark-coloured rock is very neat and effective. Its tiny rosettes are composed of leaves little bigger than a caraway seed, but they are packed so closely together as to form a minute hard cushion. *Saxifraga valdensis* also is exceptionally neat and compact and is very little larger than the former. Of larger kinds of encrusted

ways on the face of rocks, they require to be well drained during our winters. I noticed here in Exeter an *Androsace helvetica* which had been planted out three or four years ago, and developed into a very handsome specimen, but in spite of the sloping position it occupies in the rock garden, the excessive amount of wet during last November has caused in several of its stems an inclination to rot off. In this and other cases I find it a good remedy to shake a little gritty silver sand around the stems close to the rosettes of leaves, which frequently make new roots in consequence of such treatment. *Androsace carnea* looks now as bright a green as a mossy Saxifrage, and numerous flower buds are already visible.

Among other plants with ornamental foliage I will mention the pretty Pyrenean *Senecio leucophyllus*, which has almost pure white

mostly of an incurved form. Being capable of developing blossoms of huge dimensions, this class of flower finds much favour with those who exhibit for prizes. It is, however, a type which, with one or two exceptions, I do not favour, as coarseness is only too characteristic. Added to this is the fact that they are difficult of culture and not at all acceptable sorts for cultivating in a free manner without disbudding. When this mode is attempted the flowers produce a few rows of petals only, and they also exhibit large yellow centres, giving one the impression that they are neither good singles nor choice doubles. But the colours are exceedingly rich and the petals seem proof against decay, lasting a very long time in a fresh state. The earliest of this type, namely, the variety

*Edwin Molyneux*, was introduced from Japan nearly ten years ago. The introducer evidently

thought more of it than did most persons at that time in giving the sort a well-known name, but that the judgment was exceptional events have amply proved. The next year a bloom was grown which did not show the yellow disc. It was perfectly double and of huge size. I distinctly remember this blossom had the incurved shape, so that more of the old gold colour was visible than the deep rich red which makes this variety so showy. The following season, however, gave us the flower in its grandest garb, and all who saw the stand of half a dozen blooms that easily won the first prize at the great Aquarium show will not readily forget them. These blooms were 8 inches across and about 6 inches in depth. The wide petals were of great length and had a drooping habit, with just a slight curl at the tips to give them grace and show the yellow colour, which when set against the purple-crimson inner surface gives an exceptionally showy combination. Hot seasons suit this variety, for in some years (as, for instance, the last) good specimens were rare; but the autumn before (1893) it was again first, beating the best of the new introductions of that time, and when in good form it invariably finds more admirers than any sort yet to be found in collections. E. Molyneux requires a long season of growth. It is therefore advisable to strike the cuttings early. Use soil without manure of any kind and of a sandy nature in the first stages, it being an easy matter to produce a sickly yellow colour in the leaves. Its roots are thick and it takes a considerable time for the cuttings to form them, but when once a good start is made and the spring advancing, there is no Chrysanthemum that responds better to high culture. The aim should be continual repotting until the final size is reached. A 10-inch pot may be employed at that stage. I have succeeded best when the plants have been allowed to assume a natural growth, that is when the breaks have appeared without topping. The first stoppage to the shoots took place in April, and three shoots were selected. These in their turn were each allowed to show a crown bud, which occurred in July. After destroying the buds, one shoot to each stem was directed upwards and the next flower-buds retained, pinching away all side growths and pushing the plants' energies to the utmost by feeding with manures.

MRS. C. W. WHEELER.—This is pretty well known, but considering the time it has been in cultivation its appearances in good form are rare. The colour of the flower is an orange-brown shade, but the most remarkable characteristics of the variety are the universal width and thickness of the petals and its gigantic size. I cannot remember having seen a fine bloom of this grown in the neighbourhood of London. Country air is one of its requirements. It is well to strike the cuttings early and treat them as advised in the case of E. Molyneux in the young stage, but when the season is somewhat advanced this variety produces very strong growth and leaves. Large pots may be used in the final potting, and it is not easy to over-do this variety in the matter of fertilisers. Choose early buds. Those which form after the first natural break will not be too early even if they come during the end of July.

BEAUTY OF CASTLEWOOD.—When well grown this is a very fine flower, but it is only during hot seasons that we see it in good form. Perhaps the most difficult of all Chrysanthemums to form roots, it is one that has not, after several years' culture, found its way into many collections, and a number of persons have the variety Mrs. Wheeler named Beauty of Castlewood. There is, however, a great difference between the two. The latter has by far the richer colouring and is in every way the more striking. The inner surface is bright dark crimson and the outside bright gold. It inclines to an incurving shape. Full, broad, and deep when in good condition, it adds materially to the points of an exhibition stand. But its bad qualities are too many to allow it to ever become a favourite of the general cultivator. Difficult of culture up to midsummer and spare of root, it requires a deal of coaxing. An 8-inch

pot is large enough for this sort. Although a late variety, the buds may not be selected early. In such cases the blooms develop imperfect in shape and colour. The next of this type as regards time of introduction is

ROBERT McINNES. The colour of this variety is a showy orange-red shade with gold tips. On its own soil (America) it is held in great favour, but here it will never become popular. Two summers should be sufficient time to test a new kind, and in both seasons this sort has been unsatisfactory.

MISS ETHEL ADDISON.—This is an immense flower with broad thick petals, and the colour is rather a pretty shade of rose-purple. It is a strong and easy grower, but only useful for show purposes. Whilst the taste exists for Chrysanthemums of huge dimensions, kinds that have that quality and a heavy look will always find admirers, but for any other purpose except filling up a large space on show boards such kinds are useless.

DUKE OF YORK is another very popular exhibition variety, but it is coarse. Dull and uncertain in colour, with very little character in its formation, it has gigantic size. The inner shade of colour is rich and dark, but the thick wide florets incurve loosely and exhibit the outer surface, a washy grey. The plant is an excellent grower, and the sort may be made to produce blooms, perhaps not altogether repulsive, by late bud selection.

KING OF CHRYSANTHEMUMS is among the newest of the "Wheeler" class and has brilliant colouring. It is also a capital grower, and I fully expect another year's growth will bring out excellent qualities. This came from Japan.

The French raisers appear to have worked for this broad-petalled type, probably from the fact that the semi-double varieties like E. Molyneux and Mrs. Wheeler, when cultivated by ordinary methods, lend themselves to seed-bearing.

MRS. C. HARMAN-PAYNE belongs to the huge, coarse, dull-coloured section, and yet it is among the first dozen seen most often in exhibition stands. Apart from its size, however, there is nothing to recommend it unless it be that it is one of the easiest to grow. Select late buds and only allow three flowers to a plant. This treatment tends to bring it less coarse than generally seen.

PREFET ROBERT has a purple-rose colour, rather bright, and is massive in build. It is a good grower, but, apart from show purposes, not a commendable sort.

PRESIDENT ARMAND has rich dark crimson florets with silvery reverse. The flower is as refined as any of the broad petalled type, and if with further cultivation the richly coloured inner surface of the petals is more conspicuous than when first tried, this will prove an exceedingly handsome blossom. The habit of the plant is dwarf and its leaves thick and leathery.

VICE-PRESIDENT CALVAT.—This is perhaps the least refined of all Chrysanthemums and the strongest grower. The blooms are inclined to incurve and the colour is bronzy brown. Exhibitors will, I know, forget many faults if a flower has large size, but they never look at this kind. I grew the variety from the first and discarded it after one trial, but there are many persons still anxious to possess it. This again is of easy culture, its only good quality.

HENRY JACOTOT FILS may be included among this type. It is less coarse than many, and the formation of the incurving and intertwining florets is very taking. It has a dwarf habit of growth; the colours are crimson and gold.

M. DENNIS takes after the E. Molyneux style and is a rich and handsome flower. The florets are wide and long; they recurve and show the crimson inner surface. It is dwarf and requires high culture and a large pot, as well as early bud-selection.

H. SHOESMITH.

#### CHINESE PRIMULAS AT READING.

A VISIT to Messrs. Sutton and Sons' nursery at Reading is interesting at all seasons of the year. At the present time it is the Primulas and Cyclamens that are the leading features, combining, as they do, a floral display of the rarest excellence and beauty. The results achieved by the Messrs. Sutton in the hybridisation and selection of the best types of the Chinese Primula extend back over a long series of years, bearing evidence of the greatest possible painstaking on their part to bring their strain to the highest state of perfection. A visit at this season affords an objectionless in the improvement of florists' flowers as represented both by the Chinese Primula and the Cyclamen. It is only by an inspection, which is readily afforded, that the charming colours in such variety amongst the Primulas in question can be fully or adequately realised. These colours extend from the purest white to pink, from crimson to scarlet, and from purple to various shades of blue. Furthermore, there is this remarkable feature, viz., in nearly every shade of colour amongst the singles there is to be found its counterpart in the doubles.

One of the most noteworthy of the many good features in the Reading Primulas is the subdued leaf growth with short leaf-stalks. It should be borne in mind by all cultivators of the Primula that this plant is not grown, or at least should not be, for the sake of its foliage. Any practical grower will often have noted that this mistake is made, and if seed be saved from such plants the same features will be imparted to the offspring in a greater or less degree. We do not want plants with a dense and large leafy growth, but those in which the flower-spikes predominate. There are at Reading what are most fittingly termed Giant Primulas, to distinguish them from the other singles, but the use of this term does not mean that the leaf growth is of giant character; there is a robust vigour about the plants, it is true; they are stout and sturdy, but the flower-spikes and the individual blossoms are the chief features, these being of large size and unusual substance; hence the definition of "giant." Another and an all-important feature in this strain of Primulas is the variation of flowering in point of time. There are varieties for early or autumn use, others for the winter, and others, again, for the spring. In regard to this feature, it might be said by some critics that this variation is all brought about by sowing at different seasons, but it is not so; it is fixed in a most pronounced manner in the different varieties, all of which for purposes of seed-saving are sown at one time. The early kinds are going out of flower, others are just at their best, whilst the latest are only just commencing to flower. A variety, for instance, called Snowdrift is very early, coming into flower in September if needs be. Reading Pink has this same feature, whilst the latest of all are to be found amongst the giant section and the doubles, Giant Crimson and Double Red being two instances of this. At the recent January meeting of the R.H.S. Messrs. Sutton exhibited a few of their newer kinds, but the light was so indifferent that no correct idea could be formed of the colours. Seen in the span-roofed houses at Reading the difference in this respect is astonishing.

Of the giant section the following were particularly noteworthy: Giant Rosy Queen, with large flowers, the petals overlapping each other by reason of their breadth, the colour a soft rosy blush, singularly handsome and distinct, the well-defined eye adding to the effect; this is to be seen both in the Fern and plain or palmate leaf. Giant White.—This has the plain leaf, the growth being very sturdy and robust, the colour of the purest, whilst in point of size the flowers are amongst the largest of all and the spikes very robust. Giant Crimson was just unfolding its first flowers; this is a Chinese Primula of unusual excellence, having the same good properties of the Giant White in respect of the flowers, its name being most appropriate. Giant White (Fern-leaf) is a counterpart of the preceding Giant White except in regard to its foliage.

which is deeply cut and extremely handsome. Giant Brilliant Rose is a fitting companion to either of the foregoing, the colour a deep rose, becoming more intense with age, a grand decorative Primula. Giant Lilac is a very distinct and showy Primula, with singularly free growth, the flowers pale lilac-purple. Giant Pink has flowers of extraordinary size and exquisitely fringed, soft pink in colour, a most distinct and pleasing shade, being in all respects a model Primula of unusual beauty. Snowdrift, as its name indicates, is a white variety of the Fern-leaf section; its earliness has been already noted. Grenadier is quite a new shade of colour, a deep orange-scarlet, being extremely showy and of rich appearance. Rosy Queen (Fern-leaf) is of unusually dwarf growth, rosy blush in colour, a select decorative Primula. Reading Pink is the best type of a pink Primula, deep blush-pink, with paler shading; this also is an early variety and a fitting companion to Snowdrift. In Brilliant Rose is to be seen a specially fine Primula, deep in colour, extra dwarf and very free, with finely-formed flowers and large trusses. Gipsy Queen, a Fern-leaf, is the best representative of its section, with flowers of the purest white, the distinct yellow eye being very conspicuous; the leaves are suffused with a dark metallic hue, the leaf stalks being darker still. This contrast between flowers and foliage makes this a most attractive variety. Purity, another Fern-leaf, has flowers of snowy whiteness, with pale lemon eye, large in size and perfect in form, the petals so overlapping as to make the flowers look very massive. Of this there is also a plain leaf form. Pearl, which has been in commerce since 1879, still holds its own as a first-class white decorative Primula, very free and compact, with a profusion of spikes. Ruby King, another of the older varieties, has deep ruby shade, with a distinct crimson zone surrounding the eye, the growth being specially close, the flowers nestling on the foliage. Brilliant Ruby is a selection from Ruby King, and is one of the most brilliant in colour of any, being of a much richer shade than the foregoing, having its other good qualities. New Deep Carmine is a marked advance in this shade of colour, with extra fine flowers and stout trusses. This is a choice addition to late Primulas. Reading Blue is the most marked advance yet seen in this colour (the washy shade of a few years back being entirely dispelled), which is intermediate between a deep lavender-blue and that of the Forget-me-not, being quite unsurpassed at this season of the year as a decorative Primula; the growth is robust and dwarf. Of the foregoing there is also a Fern-leaf form which has even more richly coloured flowers, whilst the growth is decidedly attractive. Besides these there is a new blue Primula (not yet in commerce), quite unique in colouring, a pale soft pure blue, with the margins of the petals shading off and forming a white marginal edge, the flowers themselves of full size and the finest form, with foliage of a paler shade of green than usual.

The double Primulas at Reading are quite a feature of themselves, the advance during the past few years being marvellous. These are not appreciated nearly so much by some growers as they deserve to be. For cutting purposes, either to use at home or for sending away, they are of very great service, both lasting and travelling better than the singles. When better known these seedling doubles will beyond doubt be grown extensively. All the most serviceable colours are now represented in this section. Double White is a great stride with large trusses freely produced, whilst the growth is quite close, the spikes showing well above the foliage. Double Scarlet is of similarly good habit, with the flowers of an intense scarlet, the spikes produced in profusion; this is a grand decorative Primula. Double Imperial Purple, the plants of which are very dwarf and compact, produces flowers of an intensely rich shade, a splendid colour for effect and excellent also as a late variety. Double Red is a large and showy variety of free growth, being well suited to cool houses. Improved Double Carmine is valuable not only in its colour, but also as being one of the earliest of the doubles.

Double Rose has flowers of a soft rosy-blush shade, a charming colour, the individual blossoms being very full, the foliage of small size. Double Carnation-flaked is for vigour of growth, sturdy habit and profusion of flower a variety of the first rank, the flowers being pure white, with faint flakes whilst young, but which intensify with age; the trusses are of extra size. Double Blue in point of colour is equal to Reading Blue, but as a double it possesses the finest flowers of any, being a most noteworthy variety in every sense. Double Heliotrope is a counterpart of Double Blue save in colour, which is of the true heliotrope shade often so much in request, a singularly distinct variety. Double alba magnifica and Double White Fern-leaf are two distinct additions, both being choice varieties. Each of these varieties of the Chinese Primula is in groups; hence a comparison is rendered all the more easy, whilst the effect is also enhanced.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 12.

THIS meeting afforded abundant evidence of the severity of the weather, for on no previous occasion do we recollect such a small number of exhibits. Singular to say, however, Orchids were by far the most numerous, and these alone amply compensated for a journey in the inclement weather. It was not so much as plants but as cut flowers that these were exhibited; this is no cause for surprise, and only in a few instances had any of these cut exhibits come to any harm in transit. The labours of both the floral and fruit and vegetable committees were exceedingly light, the only recognition to a new production being made to a seedling Anthurium. The exhibit of Oranges, home grown examples, from Sawbridgeworth was remarkably fine, the fruits well ripened and possessing a very rich aroma. Another exhibit of Seville Oranges came from Derby; these were unusually large and well suited for marmalade after they had done good service as ornamental productions.

#### Orchid Committee.

First-class certificates were awarded to the three following fine Orchids, all coming from well-known collections:—

*CYMBIDIUM EBURNEO-LOWIANUM SUPERBUM* (C. eburneum × C. lowianum).—A grand hybrid, being very distinct from the type, quite as large in the flower as C. lowianum with much of its form, the growth being on the other hand quite intermediate in character. The sepals and petals are of creamy-yellow shade, the lip having the rich dark crimson markings as seen only in the best forms of C. lowianum. From Messrs. James Veitch and Sons, Chelsea.

*PHALENOPSIS YOUNGIANA*.—An imported species, but one in all probability that is nearly related to P. Aphrodite, P. Schilleriana, and P. Stuartiana. In size, vigour, and form it is like P. Aphrodite, the upper sepal and petals being white with the roseate suffusion (more particularly in the petals, which are very broad) as seen in P. Schilleriana, with the lower sepals spotted as in P. Stuartiana. A very superb variety with a combination of good qualities. From Baron Schroeder's collection at The Dell, Egham.

*PHALENOPSIS INTERMEDIA PORTEI*, of which a grand spike with five branches and thirty-six flowers and buds was shown, was not only a fine cultural exhibit, but also a superior form of intermediate, with flowers 2 inches across; sepals and petals pure white with a faint suffusion of rosy lilac at the base and deeper lilac on the column, the lip being more of a reddish tinge. From Lord Rothschild's collection, Tring.

An award of merit went to—

*CALANTHE MASUCA TRICARINATA*.—A new garden hybrid with the foliage and habit of C. masuca,

but dwarfier, the formation of the spike being similar, with the labellum of each individual flower considerably shorter; the colour is a very pale flesh with the faintest tinge of pale lilac. From Messrs. J. Veitch and Sons.

A silver Banksian medal was awarded to Baron Schroeder for some exceedingly handsome and choice cut flowers brought by Mr. Ballantine from The Dell gardens. These comprised the Phalenopsis to which note has already been made, also *Odontoglossum coronarium* miniatum, of which a huge dense spike was shown with large flowers of an intensely rich shade of crimson-brown. On this spike there were twenty-seven blooms and buds, and a cultural commendation was most deservedly awarded. Another most noteworthy spike was that of *Calanthe* Baron Schroeder, very vigorous, of great length and carrying a fine cluster of flowers, these being of an intensely dark purplish crimson, the shade slightly lighter upon the sepals and petals. *Calanthe Regneri* was represented by a very fine spike densely set with bloom; the pure white sepals and petals, also lip, with the throat and column of rosy purple, make this a most noteworthy species. C. Regneri Stevensiana has the rosy suffusion extended to the sepals and petals, being also of a lighter shade, the spike being again a fine one. Another form appeared to be quite intermediate between these two. C. Regneri fausta has the lip entirely tinted with a dark shade of rose, whilst the sepals and petals are of a lighter tint. *Phaio-Calanthe Sedeni* and its var. *rosea* were both represented by good spikes. Several *Cypripediums* were also shown, comprising the choicest kinds, as C. insigne Sandere, the unique character of which is well known, the golden, the pale green, and the pure white being in pleasing harmony. Quite in contrast to this variety was C. *Harrisianum superbum*, with flowers of the deepest bronzy purple and very lustrous (this struck us as a distinctly superior form). C. Lathamii, with its golden and bronzy tinted flowers of large size, C. Charlesworthii, of which one of the best varieties was shown, C. Sallieri-Hyeatum, a distinct and richly marked variety, and C. Calypso, somewhat after C. Lathamii, were also included, as well as another variety bearing some resemblance to C. Boxalli, but much superior to it.

Sir Trevor Lawrence sent from the Burford Lodge collection another grand spike of *Odontoglossum coronarium* miniatum, scarcely so strong as Baron Schroeder's, with a few less flowers, but in other respects equally as fine; to this also a cultural commendation was awarded. From Mr. F. Wigan's collection at Clare Lawn, East Sheen, came *Cypripedium Rothschildianum*, one spike of which bore three extra fine flowers, well marked, with the lower sepal of unusually large size, and the petals longer than usual; C. Lathamii was represented by a large well-formed flower of rich colour; *Lalia pumila* prestans by a fine form with broad petals, and the labellum of deep velvety purple; and *Vanda* (Stauropsis) *gigantea* by a good spike of thirteen flowers and buds, the sepals and petals of which are of leathery substance, rich yellow in colour, with orange spots. From Messrs. Sander and Co., St. Albans, came *Prescottia colorans*, an erect spike, flowers yellow and quite minute; also *Dendrobium Egertonii*, an old, but seldom seen species, very beautiful if not showy; *Odontoglossum Humeanum*, in the way of but quite distinct from O. Rossi majus; *Phaius amabilis* (P. grandiflora × P. tuberculosis), with the lip after the last-named parent and the sepals and petals of a clouded pink; also P. Martha (P. Blumei × P. tuberculosis), the lip again taking after the last named, but with the sepals and petals of a light golden yellow. *Dendrobium Phalenopsis Statterianum*, the forerunner of Schroederianum, was also staged, its rosy purple flowers being very beautiful. *Lalia anceps* Schroederiana, one of the very finest of the white anceps, was included, the flowers being of large size and of the purest white, save the vinous purple and golden markings in the throat. A fine spike of *Odontoglossum Coradinei albicansense*, with straw-

coloured flowers spotted with pale chocolate, and *Cypripedium Fordianum*, showing its affinity to *C. Stonei* in its dorsal sepal and in the petals, were also included.

Mr. Frederick Hardy, Ashton-on-Mersey, sent a few choice cut blooms, notably of *Cattleya Percivaliana* *magnifica*, just expanded, very superior, with larger and more richly coloured flowers, the lip being of a deep crimson purple. Other forms of the same species were shown, both light and dark kinds being included, in some of which the rich golden markings of the throat were very prominent. *Cattleya Trianae* was represented by several fine forms, the flowers of large size. *Dendrobium Schneiderianum* × *Phalaenopsis Schilleriana* and *P. Stuartiana* were also included here. From Mr. Cobb, Dulcote, Tunbridge Wells, came *Odontoglossum crispum* La Gascogne, with large, well-marked flowers, the sepals and petals pure white, quite devoid of the rosy-purple suffusion, but clearly marked with pale chocolate; the spike bore fourteen flowers. Mr. Hill brought from Tring Park a very fine spike of the old, but choice *Lælia superbiens*, a distinct and handsome species. Mr. Walter C. Walker, Percy Lodge, Winchmore Hill, sent two spikes of the exceedingly showy *Lælia harpophylla*, with its orange-scarlet flowers well developed; also *Oncidium splendidum*, somewhat in the way of *O. tigrinum*, the canary-yellow lip being very conspicuous. That noble hybrid, *Cypripedium grande*, was also shown here, the two flowers on the one spike being of deeper colour than usual. *C. Rothschildianum* was also included, as well as the old *Oncidium Cavendishi* and *Odontoglossum maculatum*, of which two spikes were sent. Mr. W. Thompson, Walton Grange, Stone, sent *Lælia anceps* in variety, also *Cattleya Trianae* and *C. Trianae alba*, with *Odontoglossums*, but the cold had been too much for them. Sufficient, however, could be seen to prove them to be good varieties in each case. Messrs. W. L. Lewis and Co., Southgate, had *Cattleya Trianae* *Ashtoni*, distinct, with a deep violet-crimson lip. From Mr. F. Burton, Highfields, Gainsborough, came hybrid *Cypripediums*, *C. suffusum*, *C. refulgens* and *C. maculosum*, the latter being the most distinct with its singularly spotted petals.

A silver Banksian medal was most deservedly awarded to Mr. Chapman, the Gardens, Cambridge Lodge, Camberwell, for what was one of the most interesting features of the meeting, viz., an excellent assortment of dried Orchid blooms, in which the splendid preservation of the colours was most noteworthy, combined with careful mounting. These comprised a wide assortment of species from various genera, some of the best being *Cattleya aurea chrysotoxa* and *C. Trianae*, *Cypripedium Youngi superbum* and *C. Leeanum*, *Dendrobium Wardianum*, *Celogyne speciosa*, *Lælia anceps*, and *Oncidium tigrinum*. Another medal (bronze) was awarded to an exhibit of photographs and photogravures of Orchid plants and blooms, which showed a high degree of skill in execution, being clearly delineated, the light and shade correct, the only fault to be found being a perceptible increase in size over the natural specimens. These came from Mons. Gravy, 164, Camberwell New Road, S.E.

**Floral Committee.**

An award of merit went to—

**ANTHRICUM PERFECTION**, one of the large-spined forms resulting from the influence, direct or otherwise, of *A. Andreanum*. This hybrid is a particularly fine one, with a large, well-proportioned spathe measuring 8 inches in length and 5½ inches in width, the colour a deep lustrous orange-red, the surface slightly uneven, the spadix being ivory white, and the foliage sagittate and deep green in colour. From Sir Trevor Lawrence.

By far the most noteworthy feature, however, presented before the floral committee was the splendid exhibit from Messrs. J. Veitch and Sons of their unique hybrid *Rhododendrons* of the *Javanico-jasminiflorum* and multicolor parentage. Of these, two boxes of cut blooms were shown,

each comprising a wide range of colour, from the purest white to the deepest yellow, the softest pink to the deepest red. The trusses of many of the first-named hybrids were unusually large, notably *No Plus Ultra* and *Conqueror*; of the latter section, Mrs. Heal was shown in its best form.

Sir Trevor Lawrence sent a well-flowered example of *Thyracanthus rutilans* with numbers of its racemes of vividly coloured flowers. This plant is not nearly enough grown. Messrs. Paul and Son had cut examples of *Azalea mollis* in various colours from home-grown plants, quite good enough for any purpose. From Messrs. Sander and Co. came *Hemanthus Kalbreyeri*, of which five large spikes of its deep blood-red flowers were shown; it is a superior decorative plant. Sir David Evans, Ewell Grove, sent a seedling *Primula* with pure white flowers of large size and well fringed; the excessive vigour, however, of the foliage was out of all proportion. This is a point in *Primula* culture that should be taken more note of.

**Fruit Committee.**

There were only a few exhibits before this committee. Messrs. Rivers and Son staged a dozen kinds of splendidly grown Oranges and Citrons, showing how well these fruits can be grown in this country with little heat. Most of the varieties staged had very fine deep green leaves, showing the robust condition to which these plants attain at Sawbridgeworth. The most noticeable varieties were the following: The White Orange, a very distinct kind with striped fruit, large, pale flesh and rind, the flavour being rich and good; the better-known St. Michael, the ordinary Orange of commerce, but splendid examples of culture, were also staged. Bettencourt, a nice looking fruit; Silver, or Plata, a splendid fruit, pale yellow, with very thin rind, flavour piquant and delicious; the Oval or Egg Orange of St. Michael, a large fruit with thick rind, but not equal as regards flavour to those named, may also be mentioned. The Maltese, a pretty fruit, with darker flesh, large, and very rich flavour, often varies much in colour, but is a free grower. A silver-gilt Knightian was awarded this collection. Five dishes of Seville Oranges were sent from Stanton Hall, Bakewell, Derbyshire, and were noticeable for their good quality and bright appearance. This variety is not only useful for its fruit, but bears a fine large flower (silver medal). Messrs. J. Peed and Sons, Norwood Road Nurseries, S.E., staged twenty-four dishes of well-kept Apples, the best varieties being *Annie Elizabeth*, *Winter Greening*, *Bismarek*, *Gascogne's Scarlet*, *Lane's Prince Albert*, the newer *Newton Wonder*, *Bramley's Seedling*, and others. Mr. A. G. Nichols, the Gardens, Nuneham Park, Abingdon, sent three dishes of Nichols' Favourite Keeping Onion for certificate. The bulbs were very good, and a cultural commendation was awarded. It was suggested that this kind be sent to Chiswick for trial.

**Annual Meeting.**

The meeting was held at the offices of the society, 117, Victoria Street, Sir Trevor Lawrence, Bart., the president, in the chair. The report of the council for the year was read by the assistant secretary, Mr. Weathers, and passed.

Sir Trevor Lawrence complimented the society upon the work of the past year, specially referring to the Temple show, which is now universally acknowledged to be the leading horticultural exhibition of this country. Last year it was superior in every way to its predecessors. He said the best thanks of the society were due to all who so kindly contributed to the success of this show. The council feared the extra day would have been a drawback to exhibitors, but they had been generous. A three-days' show was arranged for this year, and Sir Trevor Lawrence said that he might say they all looked forward to it. The regular meetings at the Drill Hall had been a great success, and the society was much indebted to those who had sent plants and flowers, and

also to the readers of papers. The great show of fruit at the Crystal Palace was also a success, and their best thanks were due to those gentlemen who subscribed the guarantee fund before the council embarked on the undertaking. This year the council had made arrangements with the directors of the Crystal Palace for a similar show. Good work had been done at Chiswick in the way of trials of vegetables and flowers, and their thanks were due to Mr. Barron, the superintendent. The tree and shrub conference at Chiswick was not well attended, no doubt owing to the bad weather. It was determined not to hold another conference this year in the gardens. Considerable repairs have been carried out at Chiswick during the past year, about £280 having been spent in all. At the last annual meeting a wish was expressed that a catalogue of the library should be published. A fund to meet the expense was opened, and £80 had been received up to the present time, but they required more. He was glad to say the work was well advanced. They had gone into the difficult question of judging at shows, and he hoped some settlement of the matter would be arrived at. The chairman spoke in the warmest terms of the work of the able secretary, the Rev. W. Wilks, also the assistant secretary, Mr. Weathers. Allusion was also made to the examination to take place in May in the principles of horticulture.

Mr. Johnston asked if the lectures could not be printed earlier in the journal. He suggested that the journal should be printed quarterly, as there was now a lot of matter of little interest. He also asked that a full report of lectures should appear, as the horticultural papers did not report fully; also that surplus seeds and plants be given the Fellows.

Mr. Parker inquired about the certificates given by the society. He said people were at a loss to know their value. He asked that the matter be looked into, as he wished to know the difference between the first class certificate and award of merit.

Mr. Marshall hoped the conferences at Chiswick would not be done away with, as they had done a good work. The houses and buildings had been put in repair and the various trials of plants, fruits and flowers were thoroughly carried out, so that the Fellows would be more interested in visiting the gardens in the future.

The chairman, in reply, stated it was not possible to distribute seeds in the way Mr. Johnston suggested, as it would not be fair to the trade, and the advertisements in the journal were a source of income that the society could not get rid of; also that the section of journal not yet printed would be published shortly.

Mr. H. J. Veitch proposed a vote of thanks to the chairman, which was carried unanimously.

Sir Trevor Lawrence was elected president, Mr. Sydney Courtauld, Mr. H. Williams and Mr. Thomas Statter as the new members of council, the Rev. W. Wilks re-elected secretary, with Messrs. H. Turner, A. H. Pearson and James H. Veitch auditors.

**THE ROYAL GARDENERS' ORPHAN FUND.**

THE annual meeting and election of children took place at the Cannon Street Hotel on the 8th inst., Mr. John Harrison, of Leicester, presiding, the officers and the committee being well represented, but of the subscribers only a few were present. The report of the executive committee set forth that notwithstanding the existing commercial depression, which affects all that pertains to gardening pursuits and the cultivation of the soil, yet success had followed their efforts, and, as far as the orphan fund is concerned, the tide of charity and benevolence flows on as freely as ever. The financial statement shows receipts higher than in 1893, while the ordinary working expenses remain about the same. During the past year sixty-one orphan children enjoyed the benefits of the fund at a cost of £787 10s. The committee recommend the election of six that day, bringing the number beneficiaries for 1895 to sixty-

four. There were thirteen applicants for election, and the committee regretted that several deserving cases had to stand over until next year. The report drew the attention of gardeners to the excellence and importance of the charity, and solicited from them more help and assistance, as the whole object of the fund is for their exclusive benefit, and an increase of assistance from the profession is urgently needed. Mention is made of the support rendered by local secretaries, and in the way of special contributions the Altrincham Gardeners' Society deserve a warm tribute of thanks; they sent a donation of £50 10s., the proceeds of a concert given on behalf of the fund. The report set forth that Mr. Harry J. Veitch had consented to preside at the next festival dinner, to take place on April 5. The cash statement showed the amount of receipts for the year ending December 31 to be £1601 0s. 3d.; subscriptions amounting to £435 16s., donations to £291 19s., the proceeds of the annual dinner, £620 19s. 3d.; the card collection brought only £27 6s. 11d., a most melancholy result, and dividends on stock, £189 9s. 9d. During the year stock had been purchased to the amount of £511 18s. 6d., bringing the investments up to £7570 6s. 10d., the balance carried forward being £829 13s. 7d. The chairman moved the adoption of the report and cash statements, characterising them as decidedly satisfactory, at the same time exhorting the gardening profession to give a greater support to what is their own fund. This was seconded by Mr. William Marshall and carried unanimously. Mr. T. B. Haywood was thanked for his services and re-elected treasurer. Mr. John Fraser was re-elected and Mr. Martin Rowan elected auditor in the place of Mr. Sharp, resigned. Messrs. Asbee, Ballantine, Cannell, Cummins, Gordon, Roupell, and Wynne were re-elected members of the committee, and Messrs. H. B. May, H. J. Jones, and J. McLeod were elected members in the place of Messrs. Bunyard, Lane and Wright, who had resigned. Mr. A. F. Barron was re-elected hon. secretary, and an amendment was made to Rule 4, relating to the re-election of members of the committee, it requiring that in the future they attend three meetings in the course of the year to qualify them for re-election. Messrs. R. Dean, A. Outram, W. Poupert, and B. Wynne were appointed scrutineers of the election, and the meeting adjourned till 4 o'clock to receive their report. On re-assembling the scrutineers reported that the election has resulted as follows: For Rosa Emily King Ward, 535 votes; Frederick Smith Parker, 517; Isabella Elizabeth Pratt, 489; Alfred Alexander Crafter, 457; Leonard Taylor, 276; and Felicia Barber, 228; A. B. Ritchie, 216; S. Small, 209; Amy Farrant, 190; F. L. Haycock, 145; R. C. Stevens, 90; and F. Barson, 42. The chairman then declared the six first-named candidates duly elected. Votes of thanks were passed to the scrutineers and to the chairman for presiding, which brought the proceedings to a close.

## NOTES OF THE WEEK.

**Iris persica.** This charming little flower is amongst the most beautiful now in the greenhouse, and it is much admired. We usually pot it up with the other bulbs and bring it gently along in a cool house after the plunging process.—W. A. Cook, *Compton Bassett, Wilts.*

**Water Lilies and the frost.**—Mons. Latour-Marliac writes, saying that although they have not been spared the severity of this remarkably snowy winter, they have not to regret the loss of all plants through it, and his beautiful collection of Water Lilies is peacefully awaiting the end of all the tempests to open their leaves and buds to the sun.

**The frost.**—Since sending my previous note on the excessive frost, our register has been: Friday (8th) morning, 39°; Saturday (9th), 28°; Sunday (10th), 26°; Monday (11th), 13°. The barometer has fallen slightly and the sky looks gloomy to-

day, but a cold and rising breeze is coming from the E.N.E.—J. C. TALLACK.

**Eucalyptus globulus.**—I herewith send you a branch of *Eucalyptus globulus*, or Blue Gum. I thought perhaps it might be of interest to you or your numerous readers. The plant was grown in an 8-inch pot. I have noticed that many more flowered last season than for some years past.—J. LEE, *Gopsall Hall Gardens, Atherstone, Warwick.*

\*\* A very fine shoot of this *Eucalyptus* smothered with seed-pods.—ED.

**The yellow Aconite at Alton.**—What wonderfully hardy little fellows yellow Aconites are! Mine began to bloom December 21. Since then they have gone through some of the coldest weather since 1838, thermometer down to 1°, *i.e.*, 31° of frost, and only sheltered by barely an inch of snow; and to day, with the thermometer at 25° at mid-day, they look fresh and bright and are opening to a faint gleam of sunshine.—WM. WICKHAM, *Binsted-Wyke, Alton, Hants.*

**The new post-card and the Continental post-offices.**—Since people have been allowed in England to use post-cards of their own with an adhesive stamp affixed, large numbers of them furnished with a penny stamp have found their way over here. Now if the words "Post Card. The address only to be written on this side," are printed on the address side, our post-office authorities will pass them, but if not, they are treated as insufficiently prepaid letters, and a fine of 3d. is inflicted. It is hardly necessary to say that this is a great annoyance and loss to firms who have a large correspondence with Great Britain.—ERNEST BENARY, *Erfurt.*

**Dried plants from Eastern Asia.**—At the Linnean Society recently, Mr. W. Botting Hensley exhibited dried specimens from the Kew Herbarium of a number of plants from Eastern Asia, several of which are of a highly ornamental character; and from his remarks thereon there is no doubt that Western China will yet yield a rich harvest of hardy and half-hardy plants, equalling if not surpassing those already in our gardens from China and Japan. The best thing of all, perhaps, was a new *Jasminum* from Yunnan, sent by Mr. W. Hancock. It is closely allied to *J. nudiflorum*, but it has primrose-yellow flowers  $1\frac{1}{2}$  inches in diameter. Among other pretty plants were two new *Gesnerads*, of which there are many lovely Chinese members only known in a dried state in this country.

**The proposed national vegetable exhibition.**—A meeting of the general committee took place at the Royal Aquarium, Westminster, on the 12th inst., Mr. H. Briscoe-Ironside in the chair, and after receiving a statement from Mr. E. Molyneux, the hon. secretary *pro tem.*, in reference to the amount of support promised by members of the trade and others, and a full discussion had taken place thereon, it was resolved: "That as the prospect of holding a national vegetable show at the Royal Aquarium is by no means of an assuring character, the carrying out of such an exhibition in September next be postponed to another year." Votes of thanks were passed to Mr. E. Molyneux for his services as secretary, he promising to retain this office until some definite arrangement was come to: to the Royal Aquarium Society for permitting the committee to meet in that building, and to Mr. H. B. Ironside for presiding.

**The late W. Baxter.**—A curiously interesting item occurred for sale at Sotheby's auction rooms on Friday last, when a selected portion of the library of the well-known antiquary, the late Mr. William Kelly, F.S.A., &c., was dispersed. The item to which we refer was a folio manuscript volume of over 400 pages, and dealt with plant lore, customs, superstitions, &c., relating to the floral world generally, collected chiefly by the late William Baxter (of whom there is a portrait inserted), with additions by Mr. Kelly himself. The volume shows very wide acquaintance with both classic and comparatively modern writers,

and the volume is a monument of painstaking industry. That it should have remained unpublished is not surprising, for publishers have learned from expensively purchased experience that books of this kind do not pay. Even the volume itself—the work of many scores of hours—was only valued at £3 2s. 6d., at which price it passed into the hands of Mr. Quaritch, the bookseller.—W. ROBERTS.

**Severe weather in South-East Durham.**—I beg to send you a few notes on the severity of the weather as experienced here from the 6th inst. up to and including this morning, the 13th, and the different temperatures taken during that time, thinking the same may be of interest, and that you would like to publish them: 6th, 24° of frost; 7th, 22°; 8th, 45°; 9th, 32°; 10th, 40°; 11th, 28°; 12th, 20°; 13th, 31°. These temperatures have been taken in an exposed situation with the thermometers on a board close to the snow line. In two other positions in the gardens quite apart from each other and very much sheltered, with the thermometers 4 feet from the ground, the readings have been just 5° above these figures. These readings are taken from Negretti and Zambra's minimum thermometers. This is the greatest frost I have ever known, and I am inclined to think that present appearances warrant its continuation. It is rather more than six weeks since the severe weather commenced here, *viz.*, December 31, since which time the ground has been covered with snow, and at present, though none has fallen for a little over a week, it is 7 inches deep.—H. E. GRIBBLE, *Wynyard Park Gardens, Stockton-on-Tees.*

**The weather in West Herts.**—The past week has been the coldest of the present winter. During the seven days ending the 11th the highest day temperatures have been even colder than what the lowest night readings would be in an average February, while on four successive nights, temperatures below zero were registered by the exposed thermometer. The present frost has now (Wednesday) lasted without a break for twenty-three days, and for the last seventeen days the ground has been covered with snow to the mean depth of from  $1\frac{1}{2}$  inches to  $3\frac{1}{2}$  inches. The lowest readings have been as follow:—

	In Thermo- meter Screen.	On Snow.	Number of hours Air Temp. remained at or about its lowest point.
Feb. 6	22 of frost	33° of frost	5 hours
" 7	24 " "	34 " "	6 " "
" 8	24 " "	33 " "	5 " "
" 9	23 " "	33 " "	30 minutes

These are all lower temperatures than any previously recorded here in February. The frost has now penetrated the ground to the depth of 19 inches, and but for the covering of snow would have descended still deeper. Owing to the power now exerted by the sun and the clearness of the atmosphere, the temperature rises rapidly during the daytime. Indeed, on the 11th inst. my solar radiation thermometer (black bulb in vacuo) at 4 feet above ground rose to 103° during the sunniest part of the day. During the fortnight ending Monday last the wind blew exclusively from some point between N. and E.S.E.—E. M., *Berkhamsted.*

**London Pansy and Violet Society's show** will be held at the Crystal Palace, Sydenham, on Saturday, July 6.

**Names of plants.**—F. T.—1, *Dendrobium Wardianum*; 2, apparently leaf of *Phaius maculatus*; 3, Laurel leaf, apparently eaten by caterpillars.

**The Wild Garden:** or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers. Fourth edition, with wood engravings from drawings by Alfred Parsons revised and enlarged. Lemn 8vo, lines cl. th. Price 12s.; well bound in half morocco, 18s. Through all booksellers.

No. 1214. SATURDAY, February 23, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHARD AND FRUIT GARDEN

### DISBUDDING PEACHES.

THIS important operation will be receiving attention in early Peach houses, and on its correct or otherwise performance depends in a great measure the success or failure of the trees in the future. That head gardeners are quite alive to the importance of proper disbudding is proved by their doing the work themselves in the majority of gardens. This was brought before me very forcibly a short time ago by a gardener from a large place, asking me if I had a man that I could recommend him as foreman for the fruit department that could be relied upon to disbud Peaches properly. On replying in the negative, and also stating that I always did that operation myself, the reply was, "It is always the same. During the whole time that I have been head gardener (about twenty-five years) I have never had a fruit foreman that had performed the work, his former chiefs having always done it." If this is general, and I believe it is, the question might be asked why gardeners do not instruct their young men more on this important matter, so that when they are called upon they may be able to do it in a correct and satisfactory mode. For the future I shall try to instruct any young fellows that may serve under me how the work ought to be done. Disbudding Peaches is like all other garden operations, viz., performed in different modes in many places, according to the practice of the head gardener, and it is astonishing to see how well Peaches and Nectarines succeed under what some men would call drastic treatment in disbudding. What I should term drastic measures is to do all the disbudding at one time, which I have seen done on several occasions in places that I was a probationer in. In each case the disbudding was thoroughly done at once, plenty of room being allowed for full expansion of wood and foliage. Although growth seemed to cease for about a week after the disbudding, the trees soon made a fresh and vigorous start and perfected fine crops of fruit. The soil in each place was very good for all stone fruits, and it is doubtful whether success would have followed similar practice on a very light and sandy soil, and it is also a question if better results would not have followed a more rational system in the gardens referred to. On all sorts of soil and on any form of trees, I believe firmly in doing all disbudding by degrees, thus avoiding any checks, with the consequent liability to red spider or other insect attacks. It is a very easy matter to commence by removing all the worst placed buds immediately they are large enough to rub out, and afterwards taking away those buds that are not required in the more favourable positions. Only a keen eye and experience will teach which buds should be left to form new wood, but as a rule it is wise to leave a bud as near the base of each shoot as possible, also one near the end to draw up the sap, and keep fruit that may be thereon from swelling. For a number of years I have allowed these terminal buds to form about five or six leaves, and then stopped any further growth by pinching out the points. By this means grand fruit is obtained, as all the strength is thrown

into the fruit. If no fruit is on the shoot and there is room for full extension of the young growth, no stopping is done, but they are allowed to go on unchecked. Where the soil is light and not of the most suitable character for obtaining large Peaches and Nectarines, I can strongly recommend the system of stopping the young growth beyond the fruit. The soil I have to manage is of that description, but by thus checking growth and giving applications of plant food, I have had many Peaches weigh up to 18 ounces each. At the same time I believe the early and gradual system of disbudding has been a considerable factor in the fruit attaining such a size, as no check to either growth or root action ever takes place, and although more time and extra work be involved by doing it, full compensation is received by the highly satisfactory progress made by the trees and their fruit.

W. G. C.

**Grape Gros Colman.**—Mr. Young (p. 94) speaks disparagingly of this Grape as regards the quality of its fruit, which I agree with, but, at the same time, it is of all Grapes the most useful for invalids, being very juicy, fleshy and not sweet, which is a great point in such a case. Where attention is paid to the culture of late Grapes for the benefit of invalids it is well to grow a few canes of this kind. Here Grapes are reserved for the exclusive use of invalids after November, none being ever used by the family.—E. M.

**Apple Devonshire Quarrenden.**—When writing on dessert Apples in a recent issue I quite intended mentioning the above Apple, as I consider it an excellent and most useful variety. Old gardeners will know it well, especially those located in the eastern counties where it may be frequently met with. We frequently see two Quarrendens catalogued, the red and the Devonshire. Some gardeners think they are identical. I do not. The former is larger, thicker in the skin, resembling the Norfolk Beaufin, and without any trace of colouring in the flesh, and altogether inferior to the old Devonshire Quarrenden. The original variety ripens in September, is fiery red externally, with a pinky flesh, and although but small, crops regularly, is of excellent flavour, and keeps a considerable time after being gathered. Twenty years ago large orchard trees of this Apple were very plentiful in Essex, the fruit being much valued for the dessert.—J. CRAWFORD.

**Digging round fruit trees.**—There is much truth in the statements of "Y. A. H." and "J. C." respecting the practice of digging too near fruit trees, whether these be on walls or in the open garden, but the limit which is very often advised to be given up entirely to wall trees cannot always be entertained, for the reason that the space is invaluable for small vegetables and salads; and in gardens of limited extent from which a large demand has to be met it is altogether out of the question to devote several feet in width of border exclusively to the wall trees. It is possible to grow early Lettuces, Radishes, Turnips, Horn Carrots and even Potatoes without disturbing the soil deeply about the roots of trees, particularly if old potting soil and decayed leaves can be put on the surface for the particular purpose of growing such extra crops. Usually a narrow path is provided for the convenience of attending to the trees and gathering their crops, this varying in width and distance from the walls according to the requirements of those in charge. By some, the paths are never allowed to be broken up with spade or fork; in other cases just the opposite happens, and under both systems good returns are known to result. The narrow border between wall and path is just the place to forward an early batch of salads and vegetables to follow those forced under glass, and there are cases where as much value is set upon these as upon the fruit furnished by the trees. Therefore the question of

digging about and cropping near fruit trees is one that must be governed by individual convenience and demand. By all means devote a good space to the roots of trees when this is found to suit the requirements of the place, but no doubt plenty of readers can ill afford to do so, and are compelled by force of circumstances to do what they would not otherwise attempt. Exactly the same applies to trees growing in open borders, although here there is not the same value set on the space for planting as near walls.—WILTSHIRE GARDENER.

### LARGE AND GOOD GOOSEBERRIES.

HAVING grown the Lancashire Prize varieties of Gooseberries for many years, I can confidently recommend the following sorts to those who may be thinking of forming a collection. Some imagine that the larger Gooseberries are without flavour. Such, however, is not the case, many of these being delicious when properly exposed to light, air, and sun. Indeed, they well repay wall or trellis culture, and are in September preferred by many to any other fruits. When grown as ordinary bushes the trees require to be kept extra thin, and as their habit of growth is somewhat awkward, the lower branches should be supported by short forked sticks. A very good method of preserving the fruit from the ravages of birds is first to construct a framework of rough wood over the trees, afterwards covering the same with small-meshed wire netting. This may remain over the trees from year to year.

Taking red varieties first, I would place Clayton in the foremost rank, this being a large handsome berry, of brilliant colour and good flavour. It ripens rather earlier than many others. Duke of Sutherland is another grand berry, the tree being a free yielder and capital grower. Dan's Mistake, a well-known fruit amongst exhibitors, must also be included, being beaten by very few of the newer varieties. Lord Derby, a variety somewhat late in ripening, is a first-rate fruit, and Speedwell is indispensable where size and appearance are important. The best white varieties include King of Trumps, Lady Leicester, an early variety; Freedom, also early; Alma and Careless, two varieties which for general good qualities have stood the test of time. The best yellows are Criterion, Leader, Leveller, a marvellous berry, seldom beaten on the exhibition table, and Trumpeter. In the green section, Drill, a very old variety, still takes a good deal of beating. Keepsake, an early ripening sort, Matchless, Plunder, and Telegraph, all of which are very fine in berry, of good colour and quality, may safely be planted with all the fore-named by those who intend exhibiting. J. C.

### DISEASED VINE ROOTS.

WITH the greater part of the roots so thoroughly dead as those sent, it is not to be wondered at that the crops were a complete failure. They could not well be otherwise. It has been my lot to have to renovate a considerable number of Vines, but never yet came across roots dead or dying in such an wholesale manner. In his footnote "J. P. M." states that these dead roots were taken from the inside border, but why did he not also mention whether the roots are alive or dead in the outside border, and then I could better have advised what to do in the matter! This is no ordinary case of failure, and the roots must have been very badly treated for them to have perished outright in the manner they have done. Root fibres, as I have frequently proved, are very easily crippled, an overdose of chemical manures frequently doing more mischief in this respect than those who use them have apparently any conception of, but it requires something extra strong to kill old roots. If the soil had not been well watered for many weeks or months this would have scarcely led to the death of the larger roots, and in any case those roots outside would have contributed more to the support of the crops as well as the inside roots than they appear to have

done. Supposing the roots both inside and outside are nearly or quite all dead from some cause not explained, it is very doubtful if the Vines are worth keeping any longer. Without an analysis it is not possible to say whether the soil of the borders is rendered unfit for the roots or not, but I should be disposed to cut a test trench a little way across the inside border at about 4 feet from the stems. From this the work of forking away the soil towards the stem could go on. If fresh, live roots are met with in appreciable quantities, then the soil is not poisonous to them, and there is also a probability of the Vines being restored to good health. But if only a very few live roots are found in the inside, and a similarly conducted search discloses the fact of the outside roots being in an equally bad plight, I should advise rooting them out and starting afresh, planting inside in a perfectly new border.

Making a new border and replanting fresh Vines is a formidable undertaking not to be entered lightly upon, especially seeing that in addition to the expense there is also a loss of one full crop and part of another to be reckoned with. We will, therefore, discuss the possibility of renovating the old ones, if eight-year-old Vines can be termed old. They are really not old in the ordinary sense of the word, as they ought to be in their prime. I and others have been successful in restoring Muscat of Alexandria Vines twenty years and upwards in age to a very profitable state, but then we had live, if very fibrous old roots to deal with. Vines just beginning to break may be lifted clean out of the soil, the long old roots being shortened to a length of 4 feet or thereabouts, and all be slung up, matted over, and kept moist, while the stale, old soil is changed for fresh soil composed much as follows: To every cartload or ten barrowloads of fibrous yellow loam add two barrowloads of fresh horse droppings, two barrowloads of old mortar or lime rubbish, two barrowloads of burn-bake, one bushel of soot, and one half hundredweight of crushed bones. After duly cleanly cutting over the ends of the broken roots, cut a few notches on the upper side of the old ones at intervals of 3 inches apart, and then relay all in the fresh soil much in the order as they spring from the stems. Vines treated in this drastic manner have actually given a few good bunches the same season, but it would have been better for the Vines and more profitable in the long run not to have cropped them till the following year, or when they were better able to withstand the strain. If Vines with their stems partly outside are treated in this manner, a mild hotbed should be formed on the border directly afterwards, this warming the soil and hastening root action considerably, and it would pay well to warm up inside borders in the same way. Vines with their roots gone principally beyond control and doing badly accordingly might first have the large old roots bared from the stems outwards to a distance of 3 feet or rather more, and after they are notched be covered with a rich compost to which "burn-bake," that is the residue from a garden smother or slow fire, has been freely added, and a mild hot-bed formed over this. By the following autumn this should have promoted the formation of numerous healthy young roots, which might be led out into fresh compost added after the whole of the border in front with the straggling roots has been cleared away. If soil cannot be collected for a fresh border or even for adding breadths, that is to say, forming a border piecemeal, those in charge will have to be content to bare the surface roots at least half way across the border, notching, but not shortening the large naked old ones. Then if these are covered with 6 inches of fresh rich compost, a mild hot-bed of leaves and manure would draw fresh roots into it, good surface treatment subsequently keeping and increasing them where they derive the full benefit of what is given in the shape of manures, to say nothing of the extra warmth and air that fall to the lot of roots near the surface. "J. P. M." might first see what can be done towards recovering the old Vines, and at the same time be pre-

paring for the possibility of having to root them out. If eyes are at once placed singly in small pots and started in a brisk bottom-heat, the plants resulting if shifted into 6-inch pots before they become root-bound would be quite large enough for planting in an inside border by the first week in May. Twice the number intended to remain permanently should be raised and planted, and then if all goes on as well as it ought to do, the supernumeraries will be quite strong enough to give two or three bunches each next season, cropping them still harder in 1897, and rooting them out when the permanent rods are in a condition to bear three bunches apiece without any after ill effects. If it is decided to root out the old Vines at once, there will be time to replant small pot Vines of last season's growth, and in this case again supernumeraries ought to be provided.

I.

#### RAISING AND PLANTING VINES.

ALTHOUGH great numbers of pot Vines are still grown for sale in strong bottom-heat, gardeners are every year becoming more opposed to planting them in permanent borders. That the plan of employing much bottom-heat is wrong must be evident to all who have had even the least experience in the matter. In many instances young Vines in nurseries are plunged in a bottom-heat of not less than 90° in not over light houses and as thick as Beans in a field, little air being admitted in order to force growth as much as possible. Under such conditions the roots formed are soft and flabby, the fibrous portion invariably perishing when the pots are removed from the plunging bed and exposed to the weather against walls and in open sheds in autumn. If anyone doubts this, let them turn one of these Vines out of the pot and examine the roots, and they will soon become convinced. Of course, those grown for fruiting in pots are allowed more room, the earliest rooted being selected and put into larger pots, but even these would be much better with less heat at the roots, and though of less circumference, yield better crops in the end. A friend of mine, a successful Grape grower, who always raises his own Vines on the non-bottom-heat principle, recently planted a house, but not having Trebbiano he purchased a Vine of it which had been grown in strong bottom-heat. It looked strong, but had few living fibrous roots, and after exhausting its stored-up sap ceased growing for several weeks until new roots were formed. These came slowly, and by the time growth had reached half way up the house, those raised at home, and which when planted were no thicker than goose quills, had reached the top and gone some distance down the back wall. As soon as Vine eyes have well rooted round the small pots and made growth 4 inches in length, they should be shifted into pots 4½ inches in diameter and again returned to the warm bed until growth is again resumed, after which they should be raised and stood on the surface for a week, and finally on a Moss-covered shelf near to the roof glass and free from draught. The Moss serves to retain the moisture.

A Vine stove or similar structure suits them well till a second shift is given and as the season becomes somewhat advanced, less heat will suffice and plenty of air become necessary. For planting canes 9-inch pots are large enough, as by these becoming quickly filled with roots early maturity is encouraged. A good holding loam, a little bone-meal, and some old plaster refuse form a good rooting medium, as manure water can always be given when needed. When hardening off the Vines in autumn I prefer placing them in a cool airy house to standing them out of doors, as they are more under control, and root moisture can be regulated at the cultivator's will. Vines grown in this way will have abundance of hard fibrous roots, which will survive the winter and promote a healthy vigorous growth when planted the following spring. In regard to planting, some prefer cut-backs, and doubtless they are best for outside borders. For

planting inside, however, I have a great liking for Vines raised the same year and planted in a growing state, say, in May or June. If the soil about the roots is warmed, the young Vines do not feel the removal at all, but go right away and soon reach the top of the house. Fresh horse manure spread on the surface will draw the roots upwards and prove an effectual trap for wireworm. I have also seen good results from shaking yearling Vines out of the pots, cutting back all long shoelace roots and repotting, planting the same out in a warm inside border when 1 foot or 2 feet of new growth was made.

J. CRAWFORD.

#### DESTROYERS.

##### HARD WINTERS AND INSECT PESTS.

AN impression prevails that periods of severe weather are instrumental in diminishing the number of enemies that gardeners have to contend with. This may be the case as regards birds, for undoubtedly many are starved to death in hard winters, but I am convinced that neither slugs nor snails are reduced in number by prolonged frosts. I remarked particularly after the nine weeks' uninterrupted frost that we experienced several years ago, and when the soil was frozen to a depth of nearly a foot, that these destructive little pests were the following spring as numerous as ever. Their long rest seemed to have rendered them more than usually voracious. I am convinced that snails will travel the whole length of the garden in search of a safe retreat for the winter. Ivy either on walls, trees, or as edgings is sure to attract them, as will also Box edging. They may be frozen as hard as a brick and will take no harm, as I have more than once proved. Where snails are troublesome among vegetable crops and the walks are bordered with Box it is well to examine it before increasing warmth and tender vegetation induce these troublesome pests to wander from their winter quarters. Many hundreds may be captured in this way before they have the time to do any damage, and as one snail will lay about fifty eggs, the destruction of a few dozens only in early spring will save the grower much annoyance later on. And here it may not be out of place to allude to the incessant warfare waged by the thrush on snails. It is, in places at least where snails abound, a mistake to kill off thrushes. Far better to encourage a pair to nest in the garden. Being surrounded by fields, I am liable to be much troubled with snails and slugs, but for several years past there has been a considerable diminution in the number of the former. This is, I believe, in a great measure owing to a pair of thrushes building and bringing out their young in the garden. By the quantity of shells laying about it is easy to see how busily the birds have been at work. The thrush is in some ways troublesome to the gardener, but I am confident that, taking the year through, he does more good than harm. As regards aphides, caterpillars, and grubs of various kinds, I am doubtful if severe weather has any diminishing effect on their numbers. The latter find their way to a considerable depth below the surface on the approach of winter, and the eggs of moths and flies are as impervious to frost as are the seeds of most plants. Were it not so, some species of insects would be almost or quite exterminated in such weather as we are now passing through. The eggs are, so to say, glued on to the plant or tree on which the perfect insect is to feed later on, and unless they fall a prey to birds they will come to life in spring, no matter what the winter may be. The blue and long-tailed tits destroy myriads of eggs during the winter months. They are constantly titting from tree to tree and eating the eggs of moths and aphides, which, invisible to the naked eye of man, are easily found by them. If one could but keep the blue tit from ripe fruits it would be the most valuable friend the gardener has.

J. C. B.

## A WATERSIDE GARDEN.

OUR illustration represents the fringe of the Water Lily pond in the College Botanic Gardens, Dublin, and is a simple example of what may be done in beautifying water margins in a permanent manner. The pond itself is not a large one and is of oblong form, and had a stiff and ugly outline before its bare banks were covered with vegetation as here shown. Some few years ago the water supply was augmented, and the margins were then roughly trenched, plenty of fresh manure being added. At the same time the best of M. Latour Marliac's seedling Water Lilies were planted in the pond, and the margins were planted with *Gunnera manicata*, the large-leaved plant on the left of the picture, and with the red and green-veined forms of *G. scabra* seen at the further end. Golden and Cardinal Osiers

room should be given them, and it is well-nigh impossible to supply too much manure either in the soil at planting time or in the shape of top-dressings afterwards. Wherever there are ponds or streams in or near the garden it is easy to make their margins full of interest by fringing them with bold subjects such as those shown in our picture, and the best time for planting is in April or May, so that a good growth is obtained before winter sets in.

F. W. BURBIDGE.

**The weather.**—No frost so intense as that we are now getting has been felt in this neighbourhood since the Christmas eve of 1860. Of that night no actual record has been kept, as the thermometers then in use here would not register much below zero, but it was the generally received opinion that from 42 to 45 of frost were experi-

when we registered 3 below zero. This only continued for one night, but much damage was done to Roses and shrubs.—J. C. TALLACK.

## CHRYSANTHEMUMS.

## THE CHRYSANTHEMUM GROWN FOR SPECIMEN PLANTS.

ONE would think, to read much that is written about the Chrysanthemum, that the principal use of this plant is to grow big blooms for exhibition. The object is laudable enough in its way, for large well-grown blooms are very beautiful, but it is possible that they are disappointing to some people who take notes of the best blooms and want to see them on the plants in their own

A waterside garden. Engraved for THE GARDEN from a photograph sent by Miss Armstrong, Clifton Terrace, Monkstown, Dublin, Ireland.

also fringe one side, and there are masses of *Osmunda*, *Lythrum*, *Arundo conspicua*, *Iris*, *Polygonum*, *Bamboos*, *Saxifraga peltata*, and *Arum Lilies* (*Richardia*). One of the most effective plants early in the summer is the golden-leaved *Iris pseudacorus*, and *Primula japonica* also flowers and seeds freely along the grassy margin. During the warmer months of the year *Nymphaea Chromatella*, *N. Marliacea carnea*, *rosacea*, *exquisita*, *N. Leydekeri rosea*, *N. pygmaea Helveola*, *N. alba*, *N. candidissima*, *N. odorata*, and other kinds are very beautiful in form and colour. *Aponogeton distachyon* flowers and seeds freely, and *Villarsia nymphaeoides* is almost too luxuriant.

Hundreds of golden carp are happy also in summer gliding about amongst the Water Lily leaves, but they are now under 8 inches of ice with the skaters gliding over them.

In the planting of such rampant growers as are the *Gunneras* and *Polygonums*, plenty of root-

enced. At that time Laurels and Portugal Laurels were killed wholesale. Hollies perished in great numbers; the buds on the Walnuts were killed—though of course they were then dormant—and even the Oaks suffered greatly, though the severe frost only lasted a few hours. It is to be hoped that the present frost will not have such disastrous results, but much damage will have been done, and many things hardy in the majority of winters will undoubtedly be killed. For weeks past we have been frost-bound, but nothing uncommon occurred until the afternoon of Tuesday, the 5th inst., when the thermometer fell rapidly, reaching zero about 8 p.m., and getting gradually lower until 37° of frost was registered. Yesterday (the 6th), in spite of strong sunshine, it froze all day, and by 7 p.m. zero was again reached, and by 1 a.m. to-day 39°, or 7° below zero, was registered. There is every prospect of a repetition of severity again to-night, the wind being easterly and the barometer high. During the past eight years the previous lowest reading of the thermometer was on the morning of January 18, 1891,

gardens. For instance, in THE GARDEN (p. 58) we read that a variety—Miss Dorothea Shea—was distinguished as being the best bloom in a large exhibition, not a word as to the plant the bloom was cut from, until W. A. Young says his plants grew to a height of 9 feet, and that he does not think he will grow this kind again. This is a fault with other varieties, and it does seem that the time has come for raisers of the Chrysanthemum to look for dwarf, sturdy-growing plants, that will not grow so tall that ladies cannot see the beauty of the flowers without mounting a ladder. Mr. Tallack on the same page writes heresy on large blooms. He likes Mrs. H. Cannell—says when well grown it is magnificent in size, but by size he does not mean depth. He hates depth, and terms it lumpiness. Surely all the best judges are agreed in giving good points for depth. The great height of the plant Mr. Tallack says is its one bad point. This spoils many otherwise

beautiful varieties. I mention the point of height because the best specimen plants are obtained from such as are of moderate growth. To obtain good specimens either for exhibition or to place upon the stages of the conservatory, I would advise putting in the cuttings early, and they should be taken from root suckers—that is if root suckers can be obtained, for I have often found it impossible to get such; whereas they can be readily obtained growing from near the base of the main stems, and in this case it may be better to dig the plants out of the soil entirely and repot in a 5-inch or 6-inch flower-pot after removing most of the soil from the roots. For ordinary purposes it is not essential that the plants should be grown to a single stem seen distinctly above the mould, but for exhibition purposes it is the general rule that each specimen should have one stem clearly visible above the potting soil, so that if any growths are produced close to the surface of the ground it is better to rub them off, as four or five shoots from the main stem are quite sufficient to form a good specimen. All varieties of *Chrysanthemums* of medium growth or below it should be grown from these old plants, the more vigorous varieties from cuttings put in either in December or very early in the year. If medium-sized or small specimens only are required to embellish the greenhouse, the cuttings may as well not be put in until March. Whenever they are put in it is as well to see that they continue to grow without any check; if they receive a check, either by becoming pot-bound or by being placed out-of-doors from a garden pit or frame without being well inured to the transition by free exposure, the chances are that the plants may be thrown into bloom in the month of May. I well remember growing on a fine set of plants some twenty years ago, and all went well until May, when the plants had grown a considerable size, and one after another formed hundreds of flower-buds, and the most remarkable part of it was that I could not trace the cause. Sometimes the cause is apparent at once: it may be the fault of the gardener sometimes, but a check to the plants' growth may occur and the cause be beyond the skill or knowledge of the best cultivator. I remember one occasion, which I may give as an illustration of the old adage, "there is many a slip between the cup and the lip." The first collection I had under my own control was in 1859, and I worked hard to get them up into a fine healthy condition. The weather was fine the first week in May and I had all the plants out by the 8th of that month, when that very night came a change and the poor plants were exposed to 8° of frost. Since that time I have always been careful not to expose the plants too freely until the end of May, and even that is not the safety point, for I remember later in 1862 or 1863 the Potatoes and Brackens were cut down by a sharp frost early in June in the county of Surrey, and many *Chrysanthemum* growers will long remember the severe frost in May of last year, when many fine collections were cut down near London. If the plants can be laid down and a covering of scrim or tiffany thrown over them they may be saved, or a light tiffany covering may be used without disturbing the plants.

It may be well to give a few directions as to the cultural requirements of specimen plants. It should ever be borne in mind that the roots are formed rapidly, and they speedily exhaust the soil, so that it requires renewal. This can best be done by repotting. Many cultivators, for convenience and to save trouble, shift their *Chrysanthemum* plants from small pots into the sizes wherein they are to flower; but plants

trained as specimens make greater masses of roots than those grown to produce single blooms. The reason of this is obvious. The specimen bloom plant has all the growths pinched out; one main stem grows up, which in time divides into three, or perhaps two only, and two or three blooms are all that will be obtained from it. The specimen plant may produce a hundred or more blooms. I have known a specimen of Mrs. George Rundle—a two-year-old plant—produce 300 fine blooms; it was grown to one main stem, of course. To produce so many blooms considerable leafage is necessary, and the more the plants spread, as rapidly do the roots increase. The best way to repot specimen plants is this: The cuttings are put in singly into deep 2½-inch pots, and when they have well rooted repot them into large 3-inch pots, from these into large 4½-inch or 5-inch, next into 7-inch, from thence into 9-inch pots, and they will produce their flowers in 11-inch or 12-inch pots. Of course, repotting must take place in each case before any of the pots get root-bound. By these successive shifts the plants grow steadily and fill the soil completely with their roots from centre to circumference. The same rich compost is needed for pot plants as is used to produce large blooms. They require weak liquid manure water as soon as the flower buds set, and by this time the plants ought to be well established in their flowering pots. As the buds set the growths may be trained into position in order to form a well-balanced, moderately dwarf plant. Some cultivators have an idea that the more dwarf a plant can be grown the better it is; indeed, I have seen immense specimens as flat as a pancake measuring 15 feet in circumference and not more than 18 inches high. This is a grievous mistake; depth should be considered as well as height, and the whole plant should possess its natural proportions. A very large specimen should be proportionately taller than a small one. The plants should, of course, be grown out of doors in an open position well exposed to sunlight, and the skill of the cultivator is exercised in keeping the leaves in a healthy, green condition until the flowers are fully expanded. Green fly attacks them, and this must be disposed of while they are under glass by fumigating. If they are attacked out of doors, tobacco powder dusted upon them from a pepper-box will have the desired effect. A rather more insidious enemy is that troublesome parasite, mildew; it is almost sure to appear in clouds in October; in fact, so certain are we of its being present, that I always syringe the plants well with soft soapy water in which a liberal proportion of flowers of sulphur has been mixed up; the plants are laid upon their sides and the under sides of the leaves are well syringed. This method of dealing with the mildew is better than that of dusting with dry sulphur; it is more effectual at first, and also more lasting. After this thorough syringing the mildew is not likely to appear after the plants are taken into the house.

It may not be amiss to treat a little of the pompon *Chrysanthemum*. The little *Chusan Daisy* is a different plant altogether from the Japanese or Chinese species. To produce good plants, the cuttings should be put in early. They would do now with a little bottom-heat, and as cuttings and young plants their treatment is exactly the same as the others, but they can be flowered as well in 9-inch flower-pots as the large-flowered section can in 11-inch ones. Smaller specimens are much more effective than large ones, but for exhibition purposes the larger the specimens are the better, if size of plant and quality in the blooms are combined.

Many years ago I cultivated very large specimen plants for exhibition, and I counted upon one of them 1400 blooms open at one time. The plant was grown from a cutting planted in December trained to one stem, and flowered in a pot 8½ inches in diameter, inside measure.

J. DOUGLAS.

**Chrysanthemum Boule de Neige.**—"E. J." scarcely quotes me fairly when criticising my remarks as to a certain similarity between Boule de Neige and Ethel. He should in fairness have included my remark, "the difference being in size, Boule de Neige being smaller flowered." As "E. J." may see if he will, I was writing at the time of the flowers themselves and not of the habit of the plant or of the section to which it belonged. I did not wish to make my notes over long, and perhaps was not quite so explicit as I might have been. However, the points of similarity which I see are these: erectness of petal, the exact shade (if I may say so) of whiteness, and the tendency to show a black centre. I do not know that this last point is a blemish if not carried to excess, as the black centre serves to intensify the whiteness of petal. The shape of petal is certainly different, Ethel being, as "E. J." says, pointed, but I think he will find that many of the petals of Boule de Neige are not rounded, but slightly indented at the end. With regard to length of petal, I think there is but little difference when taken in proportion with the size of the individual flowers. I can scarcely agree with "E. J." that neither of these two will be required, as Boule de Neige will be always acceptable for supplying sprays of bloom when large flowers are not cared for.—J. C. TALLACK.

**Chrysanthemum W. H. Lincoln.**—In writing of W. H. Lincoln "S. W. F." (p. 104) gives an instance which—unintentionally on his part—bears out my note on disbudding this variety. All I wished to recommend was to grow the plants on for terminal shoots and to reduce the buds to one on each of these instead of attempting to get sprays of bloom. I gave the number of such buds as from nine to twelve on a plant, this being the average number of shoots. Of course I was writing of one-year-old plants grown in ordinary-sized or 8½-inch pots, and I think the number of flowers given relieves me from the charge of excessive disbudding. As a matter of fact, two at least of our plants bore fourteen well-developed flowers each. "S. W. F." takes an old stool, plants it out, and lifts the plant in October, putting it then into an 11½-inch pot. No wonder the plant did its own disbudding and that the "centre bloom seemed to monopolise the sap to such an extent that the others refused to swell at all, or developed into small, mis-shapen blooms, showing but a dozen or so yellow petals." I prefer to do my own disbudding, and not to leave it in this way to outraged Nature. "S. W. F." again, unconsciously and with delicious naïveté, says that "a nurseryman offered 4s. for the plant as it stood," &c., one penny per bloom and the pot thrown in. I do not envy your correspondent the gold mine he would open up by growing "a few hundred such plants" even at double the price offered.—J. C. TALLACK.

**Carnation Duke of York.**—Has any reader of THE GARDEN any knowledge of this new tree Carnation? I learn that it is a capital winter bloomer, and that the London market growers are propagating it extensively. If this be true, it will be a great acquisition, as its colour is so much in its favour. Its fragrance also is, I believe, similar to the old crimson Clove, this fact also adding greatly to its value. I have this year grown Urial Pike for winter work, and am so far satisfied with it. It opens well and the colour is truly lovely. Its scent is likewise welcome. I do not think it will ever make so much "grass" as old tree varieties, but if the plants only grow to half their size, it will be worth growing, its colour being so distinct.—J. C.

FLOWER GARDEN.

PRIMULA NIVALIS.

THIS is a remarkably fine and distinct species now almost lost to cultivation. Dr. Regel describes it as one of the most beautiful species of the genus. It is found in the Alps of Afghanistan and Nepal, but is a common Siberian Primrose. The flowers vary from reddish or rose-coloured to deep purple and violet. *P. n.* var. *purpurea*, a typical Himalayan form, is one of the most difficult Primroses to manage under cultivation. It seems to require being kept per-

*Primula nivalis*. Engraved for THE GARDEN from a photograph sent by Miss E. Willmott, Warley Place, Great Warley, Essex.

fectly dry during the late summer and autumn. Indeed in its native habitat we are told it is buried in snow from early October until May, and although this may not account for our want of success, it seems to point to the fact that our open moist winters are the reverse of welcome to *P. purpurea*. It is a very handsome Primrose if it would only stay long enough with us to enable us to find suitable means for growing it. It grows at elevations of 10,000 feet to 14,000 feet in the Himalayas.

**Violets in frames.**—The past fortnight has been very trying to Violets, especially where not growing in heated pits, so that frost can be kept out and the lights uncovered each day. In many places frame batches have been covered up with mats and litter for some time past both by night and day. This will come hard on plants that are at all weakly or injured by spider. When they are uncovered they must be carefully dealt with, air being admitted only in small quantities at first. One of the greatest mistakes made with Violets is watering during winter. I always remove mine to the frames in October, give a good watering to settle the soil well about the roots, and then let them wait till February for a further supply. Winter waterings play sad havoc, causing wholesale damping, especially if sharp weather occurs and they have to be kept in darkness for some time. Hand-picking should be practised several times during the winter, removing all mouldy and yellow leaves and well stirring the surface soil with a pointed stick. Some advocate mulching the plants with cocoa-nut fibre in the autumn as a preventive against damp, but I never could see the good of it, and in spring it certainly keeps the sun's warmth and air away from the roots. Good cultivation in summer, so as to secure good sturdy plants, coupled with careful airing and surface stirring in December and January, are the only guarantees against the inroads of damp and disease.—J. CRAWFORD.

**The Hollyhock.**—I write a few lines on this grand autumn flower because it is the time to propagate plants for flowering next year. The

one desperate enemy we have to contend with in the process of propagation is the Hollyhock fungus (*Puccinia malvacearum*); it is in every collection, and the air seems full of the tiny spores which fly about like dust in the sunbeams. I tried to grow plants in an open field from seed where Hollyhocks had never been grown, and before the end of the season the disease was there in a virulent form. Where could it have come from? was the question, and sure enough it was in the parish, and at the railway station above all places, from whence it could be carried on our clothes as we passed to and fro. A fine florist remarked the other day when I was bewailing the disease, "How is it that we never had any of these diseases when I was a young man?" I could not answer this question; who can? The disease may appear on the cuttings or on the growths grafted upon roots. If it does, Condy's fluid can be applied to it with a small brush and it arrests its progress. The cuttings or root grafts must be planted singly in very small flower-pots in moderately moist soil. Plunge them in a moderate bottom heat and do not give them any water until roots are formed. Sometimes slow-rooting varieties require water, but it should not be given until it is seen they really need it. The succulent growths rot at the base if water is given to them too freely. Remove them from the frame as soon as it is seen they are rooted.—J. D.

COLOUR IN FLORISTS' FLOWERS.

OF course Mr. Douglas does not intend it, but his remarks—p. 91—as to the disregard by florists of his "pretty bizarre Carnation" which "had stripes and flakes of rose and purple on a white ground" are likely to lead those not familiar with florists' flowers to suppose that this combination of colours in the Carnation is "despised and rejected" by florists. It would be a pity at any rate if such an inference were drawn, for the reverse is the fact. The above colour arrangement is our pink and purple bizarre, one of the most cherished of our class Carnations. No one thinks a stand of "class" Carnations complete without this beautiful type being represented, as a glance at the reports of the exhibitions would at once show. The two leading flowers of this class are Sarah Payne, which this year celebrates its jubilee, having been bloomed as long ago as 1845, and William Skirving, which was first flowered in the wintry summer of 1879. Let anyone read the late Mr. Dodwell's enthusiastic description of the flowers in this class—pp. 98 and 99 of his book on the Carnation—if he wants to know the florist's appreciation of the pink and purple bizarre.

I saw Mr. Douglas's Harmony in flower at Gravetye in 1888, and I have Mr. Moon's excellent representation of it (THE GARDEN, December 21, 1889) before me as I write. It was a very pretty flower undoubtedly, but it could only be by courtesy a pink and purple bizarre: it had not enough of the bizarre character in it.

I also remember the pale rose flake Carnation shown at Slough on July 30, 1883. Mr. Douglas doubtless refers to Mr. Dodwell's Dorothy, a very pretty flower, which was much admired. It was a great favourite with the raiser, who, however, as he distinctly stated in his list at the time, did not offer it as a class flower. Dorothy, pretty thing as it was, was really as a rose flake but a half-developed flower. In a season or two the beautiful pale rose had faded away almost to nothingness.

Our bizarres and flakes having their own well-defined characteristics are naturally at exhibitions kept strictly to themselves. But so far from florists "despising" or "rejecting"

the beauty which belongs to Carnations of other types, classes for these are provided at the exhibitions of all our societies, so that no flower with any element of beauty in it suffers disregard or exclusion.

If a Carnation which is not a true bizarre or flake is refused admission to these classes, so equally is a flake or bizarre denied intrusion into the ranks of the other flowers.

M. ROWAN.

**Twelve good Rhododendrons.**—The following choice varieties of Rhododendrons may be relied upon for giving satisfaction where new beds are being formed. The colours are very telling, the constitution of the plants good and the habit of growth dense. Baroness Schroder, delicate white, finely spotted; Countess of Clancarty, beautiful light crimson, a magnificent truss; Earl of Shannon, fine deep crimson, showing well in the distance amongst lighter colours; Frederick Waterer, another of the crimsons, very fiery, extra good constitution; Helen Waterer, a pure white flower, with a crimson margin, very telling; John Waterer, a deep glowing crimson, extra free bloomer, plant very vigorous; Lady Eleanor Cathcart, a rose-coloured flower, with numerous chocolate spots, delicately beautiful; Michael Waterer, rosy scarlet, a very bright flower of large size, plant vigorous and foliage extra dense; Mrs. John Clutton, probably the best white in cultivation, very telling in the distance, especially when associated with scarlet sorts; Purity, a good white variety, with a faint yellow eye, an uncommon and distinct flower; Sir Humphrey de Trafford, a very showy bright rose flower, with yellow centre, indispensable; William Ewart Gladstone, very rich rosy-crimson, an immense truss, should be in even the smallest collection.—J. C.

WOOD SORREL.

(OXALIS ACETOSELLA.)

IT is well for us that of the large family of Oxalis, our familiar little wood plant should be one of the most daintily beautiful. In copses and mossy hedgerows and among the Moss under-

Wood Sorrel (*Oxalis Acetosella*). Engraved for THE GARDEN from a photograph sent by Miss Jekyll, Munstead, Godalming.

Larch and Spruce, where hardly any other plant will grow, this frail flower with its brilliant leaves makes one of the prettiest flower-pictures of early summer. It is well worth a place in the garden, best perhaps on some mossy bank among Ferns, where garden merges into wood; but it will do in almost any cool half-shaded spot where it will not be dried up in summer.

G. J.

**Supporting Hyacinth spikes.**—Difficulty is often experienced in supporting large heavy spikes of Hyacinths without spoiling their appearance. Sticks are unsuitable, as unless placed in a slanting position—which looks bad—they must be thrust through the bulb. Wire

supports are the best, being cut into the required lengths and bent at the base so as to overlap the bulb, the lower portion entering the soil of the pot. These can be gently worked in amongst the petals of the truss so as to come close to the main stem, to which they can be fastened at intervals by means of thread. If the plants are wanted for exhibition the wires are improved by being painted a green colour. The wire should not be used thicker than is absolutely necessary.—J. C.

#### FLOWER GARDEN NOTES.

**SWEET PEAS.**—A stretch of wire fencing on the top of a stone balcony some 50 feet long by 4 feet high was covered last summer with Sweet Peas, and the result being a decided success they will be used this year for the same purpose. Some stout boxes 12 inches square and as much in depth were made from 1½-inch planking, and painted outside to match the stonework of the balcony. Just a thin bit of drainage, consisting of a single layer of crocks and a handful of dry cow manure, was used, and the remainder of the boxes filled to within 1 inch of the top with a compost of three parts loam and one of short manure. The Peas were sown thinly in the boxes, and the latter placed in a cool house until the seed was up and the plants fairly well advanced. They were placed in their summer quarters in May, and brought in loosely to the wire trellis as the growth advanced with occasional lengths of twine, after culture consisting in keeping them supplied with plenty of liquid manure water and in the prompt removal of seed-pods. The variety grown was Emily Henderson, and I found it admirably adapted for the purpose. As stated in a former note, there is nothing to choose between this variety and Mrs. Sankey so far as individual flowers are concerned. They were growing together in the open last year, and towards the close of the season it was impossible after mixing the varieties to separate them. In point of growth, however, there was as much difference between them as between a very long and a short-jointed Vine rod, and it is this short-jointed, compact habit coupled naturally with very free-flowering properties that makes Emily Henderson specially suitable for growing under the conditions above named, although it must be noted that these characteristics were equally noticeable in open-air culture. If the new white Blanche Burpee, which is certainly unapproachable in size and form of flower, is equally short-jointed and free-flowering, it will be a decided acquisition. If Sweet Peas are to be sown in pots for future planting out they should go in at once. Sow preferably in small pots to avoid splitting the ball at planting-time, and when the plants are up harden off for a time before planting out. Birds will be found very troublesome where the seed is sown in the open, and a few coal ashes will have to be placed over the rows so soon as there is the slightest sign of seedlings coming through. They should be staked as soon as possible, and a few rows of cotton may be run round the bottom part of the sticks to check the ingress of birds. Where it is proposed to use Sweet Peas as a screen through the summer months and it is advisable that such a screen should present a fresh, bright appearance right through the season, the ground must be thoroughly well dug; also, if the weather prove hot and dry, heavy surface mulchings and occasional soakings of liquid manure may be required and constant removal of seed-pods will be necessary. If there is a doubt that attention cannot be given to these matters, it is better to give up the idea of a screen of Sweet Peas and to utilise such things as Canary Creeper and the green and variegated forms of *Humulus japonicus*, for if there are few more beautiful features in a garden than a healthy row of Sweet Peas clothed with flower from top to bottom, the same row has a very rubbishy appearance when comparatively bare of flower and yellow in foliage.

**PREPARATIONS FOR SUMMER.**—Where a considerable quantity of dark foliage stuff is required of the height of ordinary Pelargoniums and Be-

gonias, the highly-coloured or fine-leaved Beets, as Dell's Crimson or the Draca-na-leaved, will be found useful, and if the ground where they will be required is not at liberty, it is advisable to sow in small pots towards the end of the present month. I am not, however, an admirer of Beet for flower garden work; there is a still, heavy look about it which no form or style of planting can alter. It is much better where this kind of foliage is required to work up a good stock of herbaceous Lobelias. One gets nearly the same shade of colour in the leaf, and in addition—albeit somewhat late in the season—the grand spikes of flower. Very pretty and effective beds on a large scale can be made by planting groups of these Lobelias alternately with Pentstemons and working a carpet of dwarfier stuff—Violas for example—between them. In overhauling the stock of Lobelias that were autumn-lifted and packed away with the Strawberries in a cold pit, and that have now been cut to pieces and boxed, I was particular to note if there was any sign of the rotting of which some correspondents have complained, but found no trace of it. The majority of those plants to be raised from seed that are likely to be required for the flower garden through the coming summer need not be sown until the beginning or middle of next month, but if anything is left over that should have been included in the late January sowing, it should receive immediate attention—such things, for instance, as the hard-seeded sub-tropicals, silvery Centaureas, and Begonias. So far as the fibrous section of the last-named family is concerned when a stock of any given variety or varieties is once acquired, the old plants can be lifted, stored away in boxes for the winter, and divided and started early in the year. In addition to their value for outside planting, we find them useful as box and vase plants, also in pots for massing in large bowls for the dinner-table. If Fuchsias are to occupy a prominent position in the garden, young plants should be grown on quickly to secure stock of well-shaped stuff by the end of May, always choosing those varieties combining a compact growth and free-flowering qualities. If Dahlias are to be raised from seed, this should go in at once, and if any propagation by cuttings is required, the old plants must be soon started. It is a mistake to delay the propagation of these plants; they want rather a long season, and if only very small stuff at planting time, they are so long making headway that the season is very far advanced before they are well in flower.

CLERMONT.

E. BUCKELL.

#### SWEET PEAS.

FOR affording a heavy and continuous supply of cut flowers from June till November inclusive, it is doubtful if any annual can be named that may be said to equal in value Sweet Peas. They were always more or less popular, but since Eckford, Laxton, and others have taken them in hand a considerable improvement has been effected both as regards the size and the colouring of the flowers. We now have a distinct and beautiful selection of named varieties, all of which can be depended upon to come true from seed. It is not to be expected that these novelties can be bought as cheaply as the older unnamed forms, but according as they get into more seed growers' hands the cheaper they will become. Thus we can now buy Mrs. Gladstone, a lovely pink; Princess Beatrice, pale rose-pink, and both very popular for bunching by themselves, at comparatively cheap rates; while Primrose, a pale cream; Emily Henderson, an American novelty, and Mrs. Sankey, both fine whites; Splendour, pinkish rose, extra fine flower and long stems; Monarch, crimson and blue; Countess of Radnor; Ignea, crimson and scarlet; and Dorothy Tennant, rosy mauve, are sold at rates that ought not to deter anyone from growing them. Of the medium-priced varieties some of the best are Captain of the Blues, Princess May, pale shade of heliotrope; Her Majesty, good rose-pink, with extra

strong stems; White Eagle and Blanche Burpee, good whites; while of the more expensive novelties, Duke of York, rosy pink and primrose, very attractive; Lady Penzance, rich rose, and a fine flower; and Meteor, orange-salmon and pink, can be safely given a trial.

When the packets of seed of these newer varieties are opened they are found disappointingly small, and it sometimes happens a want of quality is also very apparent. Now unless the seed is sound and good, committing it to the open ground before it has had time to become warmed somewhat is a risky proceeding, and even if it did germinate satisfactorily, there are always enemies to be reckoned with in the shape of mice and slugs. In order, therefore, to be sure of a good display the precaution should be taken of sowing the seed under glass, and now is the time to attend to this detail. Fill 2½-inch pots with good loamy soil and sow five or six seeds in each, covering with 1 inch of soil. Place in gentle heat and give a watering if the soil is at all dry. It is worthy of note that soaking the seeds in warm water till they have swollen considerably will hasten germination by about four days. When the seedlings are 2 inches in height, transfer to either a swing shelf near to the glass in a greenhouse or else to a cold pit, where they should be kept till strong enough to plant out. Those five or six plants, or even a less number, will be found ample for forming isolated groups or for planting 6 inches apart in continuous rows. We prefer the single groups, arranging these at the back of long borders in the kitchen garden at a distance of 4 feet apart, as being in the long run less formal than, and more profitable to, rows. The sites intended for these Peas should be broken up, where possible, two spits deep and some good rotten manure mixed with each spit. If this is done it matters very little if Sweet Peas occupied the same position in the previous year or years providing the manure, or, better still, a rich compost of fresh loam, manure and fine mortar rubbish is freely substituted for or mixed with the old soil. In our case there is space for at least seventy-five good groups at the back of beds of dwarf Roses, and as the position suits Peas admirably without detriment to the Roses, it is invariably chosen for the Sweet Peas. Curiously enough, the growth first formed by Peas raised in pots rarely reaches a flowering height, and it is the growths that spring up from the base that do such good service, these growing and branching more strongly and flowering more continuously than do any plants raised where they are to flower—requiring taller and stronger branching stakes accordingly. This might not be the case if they were raised more thickly in pots, and thick sowing is also a great mistake in the case of Peas sown where they are to flower. During the tropical heat of 1893 Sweet Peas gave few or no well-formed flowers, but those planted out and liberally treated at the roots, good soakings of water and liquid manure, as well as a mulching of manure being given, did not collapse utterly, but rallied and flowered freely in the autumn. It should be remembered that allowing rows or groups of Sweet Peas to early mature a heavy crop of seed is the surest way of closing their career, and if it is done, a succession of flowers can only be kept up by making successional sowings, something after the manner culinary Peas are sown and grown. We find that wholesale cutting of the flowers, either when fresh enough for use or else directly they have faded, has the effect of keeping the plants growing healthily, and, as a rule, those planted out of pots in April continue to flower freely till severe frosts intervene. Those who wish to save their own seed should sow or plant out choice varieties in positions not too conspicuous, allowing all the earliest formed flowers to be followed by seed-pods, and netting over where necessary to protect the crop from birds. Immature or badly ripened seeds are not what should content growers of Sweet Peas.

So much are Sweet Peas valued in some quarters, that it is deemed advisable to flower some in pots as early in the season as possible. If, instead of transferring all the newly-raised plants from a

warm house to cooler quarters, a few pots of them were given a shift into 9-inch or slightly larger pots and kept in gentle heat till the roots had taken possession of the new soil, then arranging them on a staging in a warm greenhouse, a few stakes and good attendance at the roots would do the rest. They would pay well for the trouble.

SELWOOD.

### WHAT'S IN A NAME?

TO THE EDITOR OF THE GARDEN.

SIR,—I am conscious that in discussing this question of botanical nomenclature in the pages of a horticultural journal I am somewhat in the position of a wrong plaintiff pleading in a wrong Forum, for in the first place I am not myself among those who are impatient of or object to the use of names of Latin or Greek origin, and in the second the decision of the matter rests with the Olympians of botanical science who presumably lie beside their nectar-forging thunderbolts of new botanic genera careless of the sighs and twaddle of mere gardening men. Anyhow, here we are, strictly speaking, *coram non judice*. But as (to judge from the initials under which he writes) we appear to have obtained the ear of at least one savant, and as "F. L. S." (p. 88) happens to make precisely the remark that has always struck me as ostensibly the most desirable line to take in botanical classification and nomenclature, I should like with your permission to amplify the subject a little further. I, too, would wish to ask whether the creation of sub-genera would not meet the case in very many instances, and if not, why not? Science is knowledge, and the simpler and straighter that we can make the paths to the temple of knowledge the better for all. No one, of course, would deny this in the abstract. The science of botany consists in the amassing of the knowledge of and classification of the vegetation of the earth. The direct objects of the science are various, and some of them no doubt have a direct bearing on the interests of man other than those connected with his pleasures, but the vast majority of men who are concerned or who concern themselves with vegetation in any variety unquestionably do so as attracted by the beauty of flower and foliage, or by the sympathy and interest which appear to be ingrained in man towards the vegetable life that surrounds him. I say this simply to establish the fact that gardeners are at any rate not without some *locus standi* in the matter. All botanists have probably been originally attracted to the study by the mere love of flowers, and not by any innate interest in "receptacles" or in the problem whether petals are hypogynous, perigynous or epigynous; while, on the other hand, to many gardeners (myself amongst the number) botanical interest, *i.e.*, the knowledge of the fact that a plant is "wild somewhere," is an immense enhancement to the interest attaching to it.

It is, of course, well known that what constitutes difference or distinction in the eyes of ordinary people, whether gardeners or otherwise, has not or need not necessarily have any value whatever from the scientific point of view. Apart from the colour of the flower, which is nothing to the botanist, and which he not unfrequently does not even concern himself to describe, even the growth and habit of a plant is, or may be nothing also—at any rate so far as differentiation of genera is concerned. On the other hand, what constitutes botanical difference, amounting to difference of genera, is indistinguishable to the vast majority of mankind; it is only vaguely understood by many who take a general interest in plants; while the authorities themselves frequently

seem unable fully to determine the nature of the differences, and are certainly often disagreed as to their relative values. It is, therefore, this very vagueness and disagreement on the part of the doctors of science which seem to entitle one to argue that, where the question of multiplicity or simplicity is more or less equally balanced, the scales should be allowed to turn in favour of the latter rather than of the former. Any well-known class of plants will do to illustrate what I mean, but I will take the Iris, the more so as Mr. J. G. Baker's monograph of the genus is a model, as I venture to think, of what classification should be, and where it falls short of being a perfect model (as from my present standpoint I am entitled to argue that it does) it affords an excellent illustration of how the principle of adhering to the common at the expense of the less common name might conceivably have been extended. The common Flag Iris (*I. germanica*), the common Spanish and English Irises (*I. Xiphium* and *I. xiphoides*), *I. sibirica*, *I. orchoides* (a very eccentric plant), and *I. tuberosa* are all Irises. No ordinary person seeing them in flower would, of course, suppose otherwise; but equally, of course, no ignorant person seeing them in growth or at rest would suppose them to have any special affinity, for they live and have their being under obviously distinct conditions. On the other hand, a plant which any of your readers who keeps THE GARDEN may find figured in Vol. XXXVI., p. 174, under the name of *Dietes Nuttoni* is not an Iris, but is a *Moraea*, to which it is now distinctly referred under the name of *M. spathacea*; and this leads me to ask (what is, indeed, the point of the whole matter) how far Mr. Baker would have damaged scientific accuracy had he transferred the whole of *Moraea* to Iris, treating it, it may be, as section 2 of that family?

The line of demarcation, he himself states, between Iris and *Moraea* has been drawn in different places by different authorities, and, following Bentham, he places Iris exclusively in the N. Temperate Zone, and *Moraea* in the Cape, Tropical Africa, and Australia, thus treating the Equator with the respect in which Sidney Smith's friend was so lamentably wanting. Whether or no the line of the Equator or any other line of latitude be botanically watertight I cannot, of course, pretend to say, but I am bound to admit that if all from the Northern Hemisphere are Irises and all from the southern are *Moraea*, we can reasonably ask for nothing further in the way of simplification. I may remark, however, before leaving the subject that very many of the *Moraea*s have previously been named as Irises. The well-known Peacock Iris, for instance, has been named and is often still sold as *I. pavonia*. It seems, too, to have been known as *I. tricuspis*, though its present orthodox name is *Moraea glaucopsis*. To revert, however, to the main question, is there any valid reason from the point of view of science why botanical nomenclature should not be simplified by the classification as "sub-genera" of many closely-allied families of plants now treated as separate and distinct genera? Would anyone be the less wise, for instance, if my old friend *Microglossa albescens* I regret *Microglossa*, by the way, with or without his asperate) had been allowed to retain its old name *Aster cabulicus*? which seems from the date (1842) when it was first "introduced" to be an interesting reminiscence of the first Afghan expedition. I am aware that the late Professor Asa Gray recognised a terrible lot of these rank-growing *Asters*, but being so many already, a few sub-genera under the heads *Microglossa*, *Boltonia*, *Stenactis*, &c., would but consolidate

their ranks. The same thing applies to the Bellflowers, for they are certainly all bellflowers, whether they may have retained the name of *Campanulas*, or may have been transferred or referred to *Codonopsis*, *Platyodon*, *Wahlenbergia*, or what not.

With regard to specific nomenclature generally, I agree with "F. L. S." that we cannot very reasonably complain. Many of the German and Russian names no doubt look and sound clumsy and uncouth to our eyes and ears, and many of the specific names given in England and Western Europe are silly enough. But in the former case, if the Russians are so good as to go to Central Asia to find us Irises and bulbs, it is only fair that we should allow them to name them as they please; while in respect to our own backslidings in this way, it must be remembered that the enormous number of new species constantly requiring naming makes it difficult to find tolerably good epithets, all the Latin and eponymous adjectives of any point or sense having already been used up over and over again.

As to the names given by nurserymen and others to florists' flowers, the matter is of very little importance to the vast majority of the gardening public. Few people, I imagine, trouble themselves to retain names of this sort in private gardens. The only real importance of a good name is when, as sometimes in the case of such a thing as a Rose, a plant becomes very popular or "indispensable," as the nurserymen say. Painful cases of this sort unquestionably occur sometimes. One of your correspondents, alluding to the eponyms of certain popular Roses, observes that in real life "they are doubtless worthy people." This, however, need not necessarily be accepted. One of them, I feel convinced, somewhere beyond the Alps, is a lady of exceptional charm, who, had she but known the destiny that awaited her, would have arranged to curtail her Christian name to one, and that a monosyllable; but with regard to another—here in the pages of a gardening paper devoted to the promotion of all forms of æsthetic beauty—we can have no compliments to exchange. The fact that somehow or other his name has got itself attached to the best yellow button-hole Rose in cultivation can only be regarded by all right-thinking men with sorrow and reprobation.

### Books.

#### A HANDBOOK TO THE BRITISH MAMMALIA.

THIS book is the latest of the series known as "Allen's Naturalist's Library," and in many respects is the most practically interesting. Hitherto books on the British mammals have been few and far between, Bell's "British Quadrupeds" (the second edition published in 1874) being, we believe, the last to deal with the subject as a whole. In the present case the author has drawn largely from Macgillivray's "Manual." And as regards the habits of the creatures he describes, he has also had the benefit of the original observations of Mr. A. Trevor-Battye and Mr. W. E. de Winton. The valuable report of Mr. J. E. Harting on the "vole plague" has also been used to good effect, and the author acknowledges his indebtedness to Mr. A. G. More, of the Dublin Museum, for information about Irish mammals. The book opens the bats (order Chiroptera), the only mammals endowed with true flight like birds. A peculiarity of these animals is that the knee is directed backwards. Although in its flight seem-

\* "A Handbook to the British Mammalia." By R. Lydekker. Allen and Co., 13, Waterloo Place.

ing to prefer the neighbourhood of the earth, bats have been known to ascend to great heights in search of food. Its characteristic zigzag and uncertain flight no doubt gave rise to the saying, "blind as a bat," but if the defect of vision exists, the author makes no mention of it. With the public generally the bat can scarcely claim to be a favourite, being neither beautiful in repose nor graceful on the wing.

We therefore pass on to the insectivores, in some respects of structure allied to them. Among these we have the hedgehogs, moles, the shrews, rats, mice, voles, martens, polecat, weasel, hares, rabbits, the fox, wild cat, badger, otter, deer, wolf and bear. Many of them are names of terror to the agriculturist and breeders, and not always with discrimination. The hedgehog is an inveterate egg-stealer, and, on the other hand, the quantity of grubs and noxious vermin he consumes renders him serviceable in the garden. There is something also said for the mole, which, to quote Macgillivray, "by destroying vast quantities of worms and grubs is to be considered as conferring a benefit on the agriculturist." The voracity of the mole is said to surpass belief almost. A captive mole has been known to devour an amount of food exceeding its own weight in the course of a single day. Allied to the mole through the desman is the shrew, "an elegant little creature with thick, soft fur, a long, slender and pointed muzzle and a short body." Nocturnal in its habits, its shrill squeak is often heard in hedgerows and woods during the summer months. This harmless little creature was long the victim of a curious superstition. It was supposed that a shrew-mouse wherever it crept over a beast—be it horse, cow, or sheep—the animal was afflicted with great pain and threatened with the loss of the limb. A member of this family, the water shrew, has a partiality for the fry of fish and for frog-spawn. Of the carnivores, the Pine marten has almost disappeared from the southern and midland counties, though it is said to linger still in Suffolk, North Devon and, it is believed, in Epping Forest. In the lake districts it is regularly hunted with beagles and terriers. The ferret is a domesticated variety of the polecat. The stoat or ermine, though often confounded with the polecat, is in reality a very different looking animal. Its most remarkable peculiarity is the assumption in the colder portions of its habitat of a yellowish white winter dress in substitution for its normal coat of reddish brown fur. Akin to the stoat is the weasel, the relentless foe of the vole and of the common rat, and therefore a benefactor of humanity, notwithstanding the enslavements it occasionally makes upon the poultry-house. The badger, or, as it is called in many parts of England, the "broek," was formerly abundant in the British Isles, and is far from being rare, even in these days. Within the last thirty years the presence of badgers has been recorded in upwards of twenty-nine English counties. Few people, perhaps, are aware that many places, such as Brookenhurst, Brecklesby, Broekhall, Brockham Green, &c., derive their names from the badger or "broek," a nocturnal animal, living in pairs. Its favourite food is the grubs of wasps, and "except that it may destroy a certain number of the eggs of game birds, it is harmless alike to the game preserver and the farmer." The accusation of killing young foxes, which is sometimes brought against the badger, is said to be without foundation. A more founded charge is that of frightening sheep in their pens at night, by which the sheep, being often fat and heavy-coated, are liable to hurt through coming in contact with the feeding troughs. Of the rodents, the squirrel is a general favourite for its beauty, agility and dainty ways. It is less generally known, perhaps, that the squirrel will devour both young birds and eggs. This carnivorous habit, however, is said to be only a depraved taste on the part of certain individuals. The destructive family of mice and rats are dealt with at considerable length. The rat, according to one authority, is one of the worst enemies of game preservers—"a great devourer of pheasants' food, to say nothing of young pheasants"—which pro-

pensity, as the rat issues stealthily after sundown into the grass-side where the food has been scattered, gives opportunity to the brown owl to render important service. Not the least important part of the book is that devoted to the vole. Among the family Bovidae, mention is made of the Chillingham herd. These half-wild cattle are seldom met with now in British parks. They are described as handsome animals with brown muzzles, the insides and tips of the ears red, but elsewhere they are milk-white. Many of the cows are hornless. They are said to have the characteristics of wild animals in a pre-eminent degree, with some other peculiarities, such as hiding their young, feeding in the night and basking or sleeping in the daytime. Generally speaking, they are very timorous, though if pressed will turn upon their assailant. Their small size is said to be the effect of constant interbreeding.

#### NOTES FROM AN IRISH GARDEN—A RETROSPECT.

Quite a number of pretty and interesting things came into flower during the past season, notably a mass of the distinct *Helonias bullatus*. There were about 700 scapes in flower together, many of the clumps producing several each, the effect of such a number of pink-blue-anthered flowers together being charming, and I should say uncommon. *Lithospermum hirtum* in masses 2 feet or so across was excellent. In colour this is a deeper orange than *L. canescens*, and perhaps a shade taller, with a distinctly better constitution. My experience with this plant is that one should not follow too closely the information which collectors send home. I was told that it grew in dry, sandy places, which here did not suit the plant at all, and it was not until I placed it in quite a different and much moister spot that it grew freely. However, as it belongs to the Borageworts and as most of them like moisture, this was rather to be expected. Again, "dry, sandy places" is often a misleading notion, as the sand may be dry enough on the surface, but wet enough down below, and the far-reaching roots of a Borage may thus obtain all they need.

One of the most lovely things of the year was *Iris macrosiphon* var. *flava*. The flower, produced on a stem 3 inches or 4 inches high, was about 4 inches across, of a pleasing and distinct shade of creamy buff, covered all over with a sort of brick-red reticulation quite distinct and unlike any *Iris* I have ever before seen. This plant must have its toes at least in water. Another very charming plant was *Mertensia virginica roseo-coerulea*. The distinct shade of rose was clearly visible 100 yards away. The worst feature about this plant is that propagation will be necessarily slow. *Tiarella cordifolia albiflora* is quite distinct and worth recording. The flowers in this case are pure white, anthers and all. It is quite as free growing and flowering as the ordinary Foam Flower. *Arenaria montana* was quite excellent in all positions, but my best specimen was one which had taken possession of an Osmanthus about 1½ feet high, and which it completely covered and spread itself out into a patch quite a yard across. Thus it became a mound of pure white delightful to see. Amongst the Campanulae, *Edraianthus dimaricus* was beautiful, a crowded mass of soft blue about 9 inches over. The *Edraianthus* are charming plants, and it is a pity that their season is so short. *Enothera ovata* was another beauty, a stemless species in habit like a Primrose and producing its clear yellow flowers in the same way. *Dodecatheon media alba major* was a very fine thing, the scapes being nearly 2 feet high, flowers of the

largest size, very numerous and pure in colour. *Bellis sylvestris aucubaeifolia* is quite distinct, the leaves having numerous yellow spots. As this is evergreen, it is capable of affording a pretty bit of effect at a time when there are no flowers. *Funkia lancifolia albiflora* is quite a charming thing, with flowers of the purest white, and being quite hardy anywhere is an acquisition. The only pure white-flowered *Funkia* (*F. grandiflora*) is only hardy enough to flower in a few places.

Noury.

T. SMITH.

#### JANUARY IN SOUTH DEVON.

1895 has commenced its reign rigorously, the mean temperature of January having been 4° colder than the average for the last sixteen years. On twenty-four out of the thirty-one days did the mercury fall below freezing point. The lowest reading on the grass at the usual reporting station was 18.4°, but in one low and damp garden the thermometer showed 17° of frost. In spite of the cold, the sun has shown itself more than is its wont in January, 89 hrs. 45 min. of sunshine having been recorded against an average of 70 hrs. 50 min., and a record of 64 hrs. 55 min. for January, 1894.

The rainfall has been slightly in excess of the average, the latter being 3.40 inches, while 4.10 inches with twenty wet days, against 4.49 inches with twenty-six wet days for January, 1894, have been registered.

Of the last twelve months, January, 1895, has, with the exception of its immediate predecessor, December, been the most windy, 7551 miles of lateral movement having been recorded, the greatest velocity being attained by the wind on the 24th, when between 11 a.m. and noon the rate of thirty-four miles per hour was reached.

In the early part of the month the winds were for a few days at rest, and an end was set to a period of unseasonable warmth. At noon the pale winter sunlight failed to warm the frosty air. At eventide the heavens crimsoned in the west, and headlands stood out in deep purple from the haze that hid the sea, and with the crimsoning the cold strengthened. At night, when the "goddess, excellently bright," looked down from her silver crescent, a still more penetrating chill seemed to shiver from the frigid skies. These clear, hard days and silent nights proved but a prelude to weather that can but merit the term of abominable. The wind—the black north-easter that Kingsley, lover of flowers that he was, had the bad taste to greet with an ode of adulation—swept down upon us, the skies were full of snow clouds, and the ground soon white with the thickly-falling flakes. When the white carpet was 2 inches thick, the fall changed to rain, and on the heels of the rain came a hard frost, since when the earth has been encased in sheet-ice.

It is pitiable to note, in walking round the garden, the vegetable world in its extremity. Our humble friends the Wallflowers and Forget-me-nots seem to have not a particle of sap left in their limp leaves.

Long fingers of ice fringe the trailing branches of the *Muhlenbeckias* that hang at the side of the swollen cascade, while the dead leaves of the yellow Water Flag at its base are cased in solid crystal by continued sprinklings. *Veronicas* appear in sorry plight, as do many of the *Dracenas*, and the continuance of easterly gales has harmed the *Bamboos* more than has the frost. A *Crocus* or two and a few *Snowdrops* or a venturesome *Violet* from sheltered corners, a scarlet-blossomed spray of *Pyrus japonica* have been almost the extent of January's offer-

ings. The Christmas Roses have bowed their heads to the frost. The early Anemone shrivelled ere it opened, and the ruby and cream of the Safrano buds turned to black. It is the "winter of our discontent."

## GARDEN FLORA.

## PLATE 1002.

## SAINTPAULIA IONANTHA.

(WITH A COLOURED PLATE.\*)

FEW plants introduced of recent years seem likely to become more popular than the Saintpaulia which is shown in the accompanying plate. We remember that it was well shown at the last Ghent exhibition, where it was exhibited by Messrs. Linden, of Brussels. As will be seen from our illustration, the Saintpaulia, which represents a new genus, is much like the *Ramondia* in general aspect, and came to us from the Usambara Mountains, in Central Africa, being discovered by St. Paul-Ilhaire, the governor of Usambara, hence the generic name. The plant makes quite a tufted growth, with firm-textured leaves, hairy and of oblong form, whilst the rich violet-purple flowers are about 3 inches across. The plant when well grown is in bloom for months together, and is raised from seed, which should be treated similarly to that of the *Streptocarpus*. It is very fine and must be sown carefully. A warm greenhouse will grow the Saintpaulia well. Another way of propagating it is by division of the leaves, only a bulb is not formed, but fibrous roots.

## THE WEEK'S WORK.

## KITCHEN GARDEN.

**SUCCESSIONAL TOMATOES.**—The present is a good time to sow seed of Ham Green, Perfection, Challenger, or some equally prolific sort that will be ready for putting into their fruiting pots at the end of April. These, if grown on from the very first in an intermediate temperature, will produce ripe fruit in July and supplement those produced by the January-sown plants. If at the final potting a few of the smallest are put into pots one size less, they will come in most useful for planting along the back walls of warm Peach houses or orchard houses where there is plenty of light and air. These, by reason of having a more extended root run, may be trained with three separate main shoots, and, if judiciously fed when the crop is set, will continue to yield for several months. Where the roots of old Peach trees are a barrier to planting out the Tomatoes, they may be planted in Orange boxes, two plants in each box and mulched when the crop tells on their energies. Young seedling Tomatoes should never be syringed overhead, as it predisposes them to mildew and other diseases.

**EARLY VEGETABLE MARROWS.**—If an early supply of this esteemed vegetable is needed, seed may now be sown. These, if planted out in heated pits or in frames on fermenting material about the second week in April and the growths well thinned, will supply good Marrows in June. I advise sowing the seed in separate pots of small size, as, like Cucumbers, they do not care to have their roots mutilated. Time is also saved by this system. Moore's Cream and Pen-y-byd are the two most suitable varieties for early work, setting

\* Drawn for THE GARDEN by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by Guillaume Severeys.

well. A temperature of 60° is one most suitable to raise the plants in, and if a little bottom heat is at command so much the better. As soon as germinated raise the seedlings near to the roof glass and support with neat sticks as soon as the first rough leaves are formed, or being top-heavy they soon fall about and the stems get ruptured at the base. Early Vegetable Marrows also do well in large pots if placed in light positions in a comfortable temperature and trained round stakes or to wires fixed to the roof or front lights. Good loam mixed with a fourth part horse droppings and a little road grit is the best medium for the plants to root in.

**POTATOES IN FRAMES.**—January-planted tubers, especially if previously sprouted in warmth, will now be well above the soil and will require very careful treatment. Even where a fair amount of heat has been maintained in the interior by means of massive manure linings the haulm is somewhat yellow and drawn by reason of continuous coverings. As soon as the sun strikes the frames the mats and litter must be removed, but air withheld until about 11 a.m., a chink only then being given. This should be withdrawn at 1 or 2 o'clock and the top coverings again replaced so as to prevent the escape of sun-heat. Of course, if frost is absent the lights must be uncovered at daybreak and not again matted down till dusk. As a rule, there is not too much head room for growth in frames containing the earliest crops and only a limited amount of soil in consequence, and as earthing up in the ordinary way would be likely to lay the roots and young tubers bare, the best plan is to prepare a quantity of fine loamy soil, warm it, and slightly mound up with this. I am opposed to much earthing up, as it prevents the ingress of warmth and greatly lessens the yield. By this time the soil in Potato pits heated with hot water will be dry, especially round the sides close to the pipes. In such cases the middle of a sunny day should be chosen to give water, this being nicely chilled previously.

**SUCCESSIONAL BEDS.**—It is now quite time that a good spacious bed of leaves or leaves and litter was made up for bringing on the second lot of early Potatoes. This need not be of such depth as the preceding one, as sun-heat will soon greatly assist growth. Where the soil intended to supply these frames is still in a frozen state it must be wheeled into a stovehole or other warm building to thaw, as if left in the open air a fortnight or more may be lost. Fresh soil is not necessary, that used last season answering well if a fair sprinkling of some good artificial manure is added to it. For frame work at this season I find Puritan and Sutton's Seedling capital varieties. They are certainly of rather tall growth, but if a little of the material is taken from the insides of the frames before the soil is thrown in more head-room will be afforded, and the growth can be pinched before it touches the glass. As this batch will want plenty of room, an opportunity will be afforded of sowing Radishes between the rows, these being fit for pulling before the Potato haulm shades them too much. A couple of the strongest shoots will be ample to leave to each tuber, dense growth in frames being ruinous. Some of the more advanced tubers of early sorts may now be removed from the store room and placed in a warm greenhouse ready for planting in cold pits or rough home-made frames in March. These will afford new Potatoes several weeks in advance of the earliest planted on warm borders in the open air. Snowdrop comes on quickly and yields well under cool frame treatment, I myself having grown it in such a position the last two years.

**SECOND EARLY PEAS.**—With the hope that snow and frost will soon come to an end for this season, means should be adopted for getting the ground intended for second early crops into condition as soon as possible. Any south borders or sheltered nooks should be cleared of snow on the least indication of a thaw. This is a great gain, as if it is allowed to melt and sink into the ground it is rendered cold, and early root action becomes impossible. I have frequently advised sowing Peas on shallow ridges, particularly where the soil is

not of the lightest and drainage perfect. This will be especially beneficial this season, and as there is extra moisture in the ground, dryness at the roots before the crop is gathered need not be apprehended. The ridge system is more important in the case of the wrinkled Marrow section than with the round-seeded, the latter not being so liable to rot. Where ground is scarce it is well to sow an equal quantity of first and second early Peas in the same rows, not drawing drills in the usual way, but raking out cavities with the spade 9 inches in width, and sowing the seed thinly. Those who did not sow last autumn, or who have not raised a batch of early Peas in pots or boxes, will this season find the disadvantage of trusting to open-air sowings for the first supply. Peas in small pots sown in January and which have been in a cooler house for some time past should now be removed to a cold frame to harden off preparatory to planting them in their permanent quarters in March. Care must be taken not to give them too much water, particularly for the first fortnight, or it may cause the growth to turn yellow and fail. They must be protected by means of fish netting even if the lights are only tilted, as sparrows will find an entrance and quickly spoil the lot.

**EARLY TURNIPS.**—These do well in moderate heat, and well repay the trouble of culture. If a bed of good depth of leaves is made up to accommodate either a single or double frame, this being furnished with from 6 inches to 9 inches of light loamy soil and the seed sown thinly in shallow drills 9 inches apart, it will quickly germinate. When the seedlings can be handled they must be freely thinned, as crowding soon ruins young Turnips. A second thinning must follow when the rough leaves are formed, finally leaving the plants 8 inches apart. Abundance of air must regularly be given, avoiding draughts and cutting winds, and liberal waterings administered, as Turnips delight in plenty of moisture. For this reason it is advisable to grow them on flat beds rather than sloping ones. Sown now they will be fit for use in May. The best variety for the purpose is Early Milan.

**EARLY PARSNIPS.**—This nutritious vegetable does not always receive the attention it deserves. The sooner the seed is sown the better, providing the ground is in workable condition. Scuffling with five-tined forks so as to aerate and sweeten the surface is very beneficial where the soil is not of the lightest. If a few rows are sown at the end of the month, the roots will be ready for lifting in September. Deep tilth, freedom from stones and lumps of soil to the depth of 1 foot or 15 inches are imperative if clean-grown roots are desired. Parsnips should also follow some other crop, and not be specially manured for, or coarseness and rust are sure to follow. Sow the seed in shallow drills about 18 inches apart, and as soon as the plants are large enough to handle thin moderately to prevent drawing. Where extra large roots are desired for exhibition, plenty of room must be allowed between the plants, those at the final thinning being left 1 foot from each other in the rows. On very shallow soils the ridge system may be practised; this increases the depth of soil for the roots to work in, and also tends to keep the young roots warmer till growth is vigorous. Where the soil is unfit for growing Parsnips holes may be made with a crowbar, these being filled up with light friable soil. In this case the rows may be about 18 inches apart, and the holes about 1 foot apart. For first sowings the old hollow crowned variety is hard to beat.

**EARLY OPEN-AIR CARROTS.**—If possible a little seed of Early French Horn and Early Nantes should be sown before the end of the month, and if a slightly raised bed in a sheltered position was prepared as advised some weeks ago, setting will by now be completed, and a little surface stirring and exposure to sun heat will render it fit for the reception of the seed. After sowing, frost may be kept at bay by covering with dry litter at night-fall when frost threatens, removing the same early next morning. A little wood ashes strewn along

the drills after sowing is a good preventive against grubs and other insects.

**SMALL SEEDS.**—Such things as the forcing Cauliflowers or Red Cabbage Lettuce sown in heat some time since must receive attention in the matter of thinning and hardening off. Remove the boxes or frames to a warm greenhouse, elevating them well up to the roof glass, water carefully, and sprinkle with wood ashes on the first appearance of damp.

J. CRAWFORD.

### FRUIT HOUSES.

**EARLY VINES.**—With the outside temperature lower than we have experienced for years it is difficult to maintain a sufficient temperature without a drying heat, the latter encouraging thrips and red spider. Those who have small sheltered houses will reap much advantage over those with larger ones, as in these latter it is more difficult to maintain a genial atmosphere. Much may be done at such seasons by covering the outside glass with a warm cover; indeed, only a slight cover of any kind is beneficial, as it breaks the force of cutting winds and prevents the hard firing so harmful to Vines. If the advice given in former calendar notes has been carried out, the Vines will be making good progress, and if in pots near hot-water pipes with hard firing more moisture will be required at the roots. If allowed to dry there will be trouble in the way of bad setting and other evils. All parts of the house should be freely damped over, except the Vines and hot-water pipes, as volumes of steam are most injurious to the tender foliage. There should be no delay in removal of superfluous bunches with such varieties as Black Hamburgh, as these rarely fail to set well, whilst the shoots or growth should be stopped at the second joint beyond the bunch, also the lateral growths as they push out at the first leaf, but this advice may be modified should the canes have broken unevenly. In some cases it may be well to leave a greater length of wood from the bunch or later lateral growth to tie in bare places. With pot Vines it is also necessary to throw all the vigour possible into the bunches, so that it is not wise to allow too much growth. The leading lateral growth may be allowed to run freely with planted canes, as if there be room this will cause a free root growth, but should the lower growths be at all weak it is advisable to stop them two or three times during the formation of the bunches and swelling of the fruit. After the bunches are set, if the Vines are in pots some rich surface-dressing should be given in the way of Thomson's Vine manure mixed with good loam, and at every other watering tepid liquid manure may be given. Vines planted out will take liberal supplies if the borders are shallow and well drained. Thinning should be done as early as possible to promote the swelling of the berries left on the Vines, as these latter when they take the lead grow rapidly. Temperatures in such seasons as this should be low than otherwise, 60° to 65° at night being ample, with a rise to 70° by fire heat by day and a liberal rise by sun-heat. Ventilation will be difficult, though there be bright sunshine, and admit air in small quantities through the front ventilators, as then it can be warmed by passing over the hot-water pipes, and with bright sunshine with a chink on the top ventilators there will be no danger.

**SUCCESSION VINERIES.**—The Vines started early in the year will have broken freely, and in most cases syringing should cease. There is much gain in having a thick covering of fermenting material on the borders, as this greatly assists the Vines, and with those started early this month it may be well to add a little fresh manure to that which has got exhausted. This will assist the buds to develop and save much time in syringing and fire-heat, and as the bunches show reduce them to the most shapely. Where high finish—not mere size of bunch or weight of fruit—is wanted, cut away freely. Great care will be required in tying down the lateral growth: indeed, there should be no hurry if the wires are a good distance from the glass. Unfortunately, in many houses they are

close, and in such cases the rods may be given more play, and only those growths gone over daily and slightly lowered which touch the glass. The same remarks as to extension of lateral growth advised for early Vines apply here, but more forcibly, as with later houses more space can be spared for extension and encouragement of free root growth. High temperatures also mean a weakly growth, especially at night. In severe weather 55° will be sufficiently high, even up to the flowering period, when the temperature should be raised 5 to 7, or a trifle more for Muscats. In mild weather 60° at night is none too high for Vines, but my remarks apply to such weather as we are having at the time these notes are written. As the sun gets more power it will be an advantage to allow the thermometer to run up to 80° or 90°, and during such admit air, closing always before 1 p.m. and keeping the fires quiet from 9 p.m. to closing time. Without sun-heat the day temperature may safely range 10° more than that advised during the night. Well water all inside borders before the flowering period, as it is best to do this to enable them to tide over that time. During dull sunless weather less atmospheric moisture must be given and the rods gently tapped to distribute the pollen. Avoid draughts of any kind, give air sparingly, and in the case of shy setting kinds such as Muscats, Alnwick Seedling and some of the large-berried varieties fertilise at mid-day with a rabbit or hare's tail or camel's-hair brush. I prefer the former, using the pollen of the Black Hamburgh, of which there is always abundance.

**LATE VINERIES.**—The cleansing of these houses should now be finished, and the borders, if inside, given a thorough soaking of rain water, also any top-dressing required attended to. Use good turfy loam with a liberal proportion of Thomson's manure for the Vines. In many cases top-dressings may be useless through the roots being so low down. In such cases remove a large portion of the top inert soil and place the new richer material directly over the roots. If the Vines are deficient of roots, they may be much improved by placing some warm litter over the surface after the top-dressing when the house is started. With warmth as advised, new roots will be formed in the new surface dressing, and these may be fed during the season. With the borders in the open it is well to do this work a few weeks later, as the Vines do not push out new roots until the buds are breaking freely. If the work be done just before that time the soil is warmer, though it is well to encourage new root action by covering the surface with warm litter for a few weeks. With regard to starting late Vines much depends upon the varieties. Start Muscats and Gros Colman early in March, as by so doing there will be less need of fire-heat at the finish. The fruit hangs better and is superior in every way. With Black Hamburgh there may be a few weeks' delay.

**POT VINES FOR NEXT SEASON.**—These are secured from Vines struck last season. Few can grow their canes sufficiently strong in one year to fruit very early the next. There is not time to mature the canes for hard forcing. For this purpose the young canes should have been cut down at the end of the year, and now be in a condition to report if the shoots are 2 inches or 3 inches long. I usually get my young canes the first season into 5-inch pots, and they are then large enough to place in their fruiting pots direct, and will have been started for this purpose in a vinery a few weeks ago. When repotting remove all loose soil and drainage, loosening all long roots, and repot in good turfy loam, a little old mortar rubble or wood ashes and a sprinkling of bone meal. Have clean pots and ample drainage. Pot firmly, leaving at least 2 inches of space on the surface for watering. If the plants are small, pot into 8-inch pots after shaking out, and when the new roots are all round the ball, shift into the pots in which they are to fruit. If bottom-heat can be given so much the better to start the plants, but let it be as mild as possible. Water very sparingly, giving tepid water when required, and as top-growth in-

creases they should be tied up near the light to encourage a sturdy growth. I omitted to state that in potting keep the old ball well down so that the shoot from the base is close to the soil, as this will induce new roots to form from the base of the new growth. For fruiting canes a portion of ½-inch bones may be used on the rough drainage. Those who must grow their own canes will have saved their best prunings. These should have been prepared a month ago for the production of strong canes. If not yet done no time should be lost. I prefer to place the cuttings after potting up in a frame or cool place for a few weeks, and then plunge in a steady bottom-heat of 80°. They then rapidly make roots; whereas if placed direct in strong heat before the cut portion is callused over they make top-growth in advance of the roots, being weak and rarely making good plants. After placing in heat moisture must be given very sparingly at the roots, damping the tops over with tepid water occasionally.

**CHERRIES UNDER GLASS.**—The Cherry will not bear hard forcing, and requires much care in the earlier stages. When fire-heat is applied there should be no lack of air. Many who only have one house start their trees at this date, and with gentle forcing get fine fruit of splendid flavour. As the Cherry can be grown so well in narrow houses or cases, it well repays for the space occupied. If trained to a back wall the trees fruit grandly. A Cherry house may also be used for so many purposes after the crop is cleared, that I wonder more trees are not grown under glass. The best Strawberries I ever forced were in Cherry cases, with a shelf suspended from the roof, this treatment just suiting the plants. The house should be started at 45° to 50° at night, with an increase of 10° by day, but in severe weather I would advise the minimum, as it should be the aim of the cultivator to force slowly, thus obtaining strong bloom, otherwise much of the bloom will fail to set, or will drop as soon as a set is secured. In the case of Cherries it is not well to allow the house to get as hot as advised for Vines. With more warmth give air freely and do not let the trees suffer for want of moisture, the syringe being used early in the day and at closing time. It is best to give the borders a good watering before the bloom opens, and should there be the least trace of green-fly, fumigate lightly two or three nights in succession before the flowers open and the trees are dry. When in bloom the temperature may be raised, allowing 5° by night and 10° by sun heat, and in dull weather it is well to fertilise the bloom at mid-day or when the pollen is ripe or dry. Trees in pots in cool or orchard houses should be placed in the cool end of the house, and at the start give plenty of air, but they will require careful watering. The buds drop badly if there be excess or otherwise. It is best to give both pot and planted-out trees a thorough soaking when required. It is when the surface is only just moistened that buds drop. G. WYTHES.

**A useful climber.**—One of the very best and most attractive climbers for the conservatory is *Hibbertia dentata*. A very small plant soon covers a large space, its glossy leaves and delicate yellow flowers being very ornamental at this season of the year. No better subject could be chosen for covering walls in conservatories or carriage courts, owing to its evergreen nature. It succeeds well in a mixture of loam and peat, with sufficient rough sand to keep it open. Being a vigorous rooter it requires a good quantity of water during the summer months, and during winter must be kept in a fairly moist condition. It requires a trellis to support it, and the young lateral growths should be allowed to hang loosely and not be tied in formally.—J. C.

**Rubus australis.**—It may be of interest to Mr. W. J. Bean, who writes concerning the above plant at p. 109, to know that so far north as Chester a plant of this *Rubus* which had remained exposed for several years survived the severity of the winter of 1879-80 with no protection of any kind. It will be remembered that this winter

was unusually severe, the thermometer in some instances falling nearly to zero. If I remember rightly, 28° was the maximum registered by the writer, but the frost was sufficiently prolonged to kill outright some 2000 plants of hybrid Pentstemons in a cold house, not a single plant escaping. Yet, notwithstanding, a dense impenetrable bush of this *Rubus* was only injured at the points and browned more or less. The plant was in an open bed in a mixture of peat and vegetable soil. When planting it in the open it is a good plan to place a few thin pieces of sandstone about the collar of the plant. This in times of severity will stand the plant in good stead, or if planted on the rockery against the sloping side of a sandstone block its roots will descend deeply and the *Rubus* receive protection therefrom. I have never seen it in flower.—E. J.

## ROSE GARDEN.

### WINTER ROSES.

THE remarks of "D. T. F." at page 83 are worthy of consideration by Rose growers, as the question is introduced whether the British grower can compete with the growers in the south of France. "D. T. F." says, "Surely it is not beyond the ability of the English growers to flood the markets with home-grown Roses for Christmas," &c. Flooding the markets with white Roses at Christmas is a large order, but it would not be beyond the reach of British talent or British money. The all-important question is, would it pay? It would if a good price could be obtained in the wholesale market for the Roses, but in the present state of the trade it would, I fancy, be spending half-a-crown to earn a shilling. Whether the Roses are grown in pots or planted out, they require attention, and must be under the care of gardeners who know how to force flowers. Suppose they are grown in pots, as being the most convenient. They must be prepared for forcing during the summer, and to do Tea Roses in pots well, they ought not to be outside at all. They must rest after flowering, and as the flowers are cut about Christmas, it would not do to turn them out of doors, nor yet to thrust them into any out-of-the-way corner under glass. They must be exposed to light and air in a good position in the houses during the spring months. The plants will make some good growth and flower again in summer if allowed to do so. Repotting must be attended to annually, and not the least part of the cultivator's care is to keep the leaves free from insects and mildew. In fact, to keep Roses up to the high standard of excellence whereby good flowers only can be produced requires as much labour as is necessary to grow greenhouse or stove plants. Let us look at the comparative case with which Roses are grown in the south of France and the Genoese Riviera. There is scarcely any rainfall from the end of April to the end of September. The Roses during those months almost cease to grow and lose their leaves. In August the gardeners prune their Roses, or in the first fortnight of September at the latest. They begin to bloom late in October, and continue flowering until the middle of January. The three principal Tea Roses grown are Safrano, Mme. Falcot, and Lamarque. They are cut in the bud state, and open out when placed in water. The Roses produce immense quantities of bloom; whereas Roses in pots forced early would not produce many. Good sized Rose bushes in 8½-inch pots would not produce on an average a dozen blooms, if so many; probably nine would be nearer the average, and as the flower girls offer them in November and December in the streets at a penny apiece, one may have

some idea of the wholesale price. It will never be worth while to flood the markets with English grown Rose blooms in winter, either of *Niphetos* or any others. Nearly all the English cultivators of Rose blooms for market know the value of *Niphetos* for cutting. It is more grown than any other Rose, except, perhaps, *Maréchal Niel*.

The culture of Tea Roses in private gardens is another thing, and strongly to be commended. I cut some beautiful Tea Roses this morning, and hope to continue cutting them until Roses come in again out-of-doors. I do not try to get them in before Christmas, as it does not seem to be worth while to compete with the *Chrysanthemums*, but those who want Roses in November and December must imitate to a certain extent the climate of the Genoese Riviera. Let the Roses rest by being kept comparatively dry at the roots during summer. Prune them about the end of August to the end of September, and start them growing in an ordinary greenhouse. They require no artificial heat until the end of October, and a temperature of 55° as a minimum will be sufficient for them during the months of November and December. This is easily kept up with a dryish atmosphere, as zonal *Pelargoniums*, *Carnations*, *Bonvardias*, and *Cyclamens* will thrive well under the same treatment. It is easy to see what a beautiful show of bloom may be kept up during those dull and dreary months of the year.

J. DOUGLAS.

### NEW ROSES OF 1893-1894.

THERE were a fair number of new Roses sent out in the above years, and if not so numerous as in the past—for which I believe all of us have little regret—a few really good ones may well be mentioned before the planting season is over. With the prospect of many gaps in our Rose borders and the fact that most of these new kinds can be obtained in pots better than from the nursery rows in the ordinary way, I thought a description of them might be useful.

CLIO was sent out by Messrs. W. Paul and Son last year. I have seen this Rose in superb form at the Temple shows of the R.H.S. A beautifully delicate flesh colour, with a shade of rosy-pink in the centre, excellent shape, full, and with some of the handsomest foliage we have, it is, perhaps, one of the most distinct Roses recently introduced, and for pot work cannot be surpassed in its colour.

CLARA WATSON comes from Oxford and has been well shown again during the past summer—a Hybrid Tea of promise, more especially for cutting from in the garden. It is a beautifully tinted salmon and pink, being much brighter and fresher in the centre, very free blooming and vigorous, but is rather more subject to mildew than the majority of Roses.

CAPTAIN HAYWARD is another good Rose for garden decoration, and is sometimes double enough for the exhibition stand. The petals are very long, and as a bud its deep carmine-crimson is most taking.

CORINNA is an almost indescribable colour—rose, bronze and a coppery flesh combined. The flowers are large and freely produced, while we can wish for no better grower than this production from Waltham Cross.

CRIMSON RAMBLER need not be described, and yet there may perchance be one or two who have not purchased it. For a pillar, a wall (inside or out), in fact for any position where the Rose can be grown, this charming new Polyantha cannot be misplaced. Its tremendous growth rivals, if it does not surpass, that of *Rôve d'Or*. Its huge trusses of carmine blossoms are simply superb.

CHARLES GATEK is a very deep crimson, of immense size and substance, about midway between a clear crimson and maroon, each of these two shades being distinguishable in different lights.

COMTESSE DE GALARD-BEARN was sent out by Bernaix last season and is one of the Mme. Carnot and W. A. Richardson class, but larger and fuller, and of a bright canary-yellow shade.

ALISTER STELLA GRAY—originated in that famous Rose garden at Bath—is a tremendous grower, particularly free-blooming, and reminds one of a cross between *Perle d'Or* and W. A. Richardson. The trusses of small blossoms are delightfully distinct, and so freely borne that one can truly cut and come again.

BEAUTE INCONSTANTE is well named. Carmine, yellow and coppery fawn are all present in some flowers. We may see any two of these, or occasionally only one. It is not a very strong grower, but well worth growing if only for its delightful buds.

BRIDESMAID, another sport from Catherine Mermet, is identical with that except in colour, which is much deeper and may be described as a clearer as well as a brighter pink. It is an improved C. Mermet in colour with every other good quality of this grand Rose.

BELLE SIEBKRECHT many of us saw when so well shown by its raisers. It won the gold medal of its year, and from the ground plants shown me one can judge of its growth. I was much taken with it upon more than one occasion while exhibited under the name of Mrs. W. J. Grant, but the entire stock passed into American hands, and they have failed to send it out at the date advertised. We may look for it this spring. It is a hybrid Tea of bright rosy-pink shade, a free bloomer and sweetly scented.

CELESTIN PORT is one of the most peculiar shaded H.P.'s we have, as the centre is distinctly tinged with that coppery red found in many Teas. Vermilion and shaded crimson of a velvety hue are the remaining colours. It is large and of good shape.

DIKE OF YORK, a China Rose from Messrs. W. Paul and Son, is most variable in colour, sometimes tipped with rosy pink on a white ground, and at others rosy pink only, while I have seen these two shades in many combinations. Good for the garden or post.

GRAZIELLA we already had twice among Roses, but this novelty of 1894 is a very promising Rose and quite distinct. A creamy white with tints of clear flesh, a good grower, and one I quite expect to become very popular.

GERMAINE TROCHON is another of those delightful Hybrid Teas from Pernet-Ducher. The edges are rose, ground colour salmony flesh, and centre clear nankeen-yellow.

LORNA DOONE, one of the small class of Bourbons, is a decided addition in every way. A deep magenta with carmine and scarlet shadings. Full, large, a good grower and free bloomer.

MME. JOSEPH COMBET, a free growing Hybrid Tea, is full of promise. A delicate creamy white shaded with rose, and the bloom rather larger than the majority of this new class.

MME. E. HELFENHEIN is described by Guillot as chamois yellow, with shades and veins of carmine-rose and apricot; a vigorous grower and most distinct.

MAMAN COCHET, a peculiar shade of carmine mixed with yellow and salmon, is really a superb addition to our climbers.

MARCHIONESS OF DOWNSHIRE won the gold medal last year. It is the most distinct and beautiful satin pink with a soft rosy shading we have. Very large petals, a full flower of great size and good form. As seen at the Crystal Palace, where it won first prize for twelve of any new Rose, it was grand.

MARCHIONESS OF LONDONDERRY is a clear ivory white that also won a gold medal, which it well deserved. The substance of the petals is most remarkable, and it flowers well both on cut-backs and maidens.

MRS. SHARMAN CRAWFORD gives us quite a new shade of rosy pink and with a distinct shade of white at the base of each petal. It is large and of perfectly imbricated form, while its flowering and growth are excellent.

MRS. HARKNESS and PAUL'S EARLY BLUSH are now decided to be synonymous, a fact I was con-

vineed of from their first purchase. A pale blush sport of that delightfully sweet-scented and early blooming Rose Heinrich Schultheis.

MRS. W. C. WHITNEY we do not know much of, but it comes from America with a wonderful reputation as an extra free bloomer, long clear pink flowers, and sweetly perfumed.

PIERRE MERCADEUR is only a moderate grower, but it produces exceedingly large creamy yellow and copper shaded blooms.

PRINCESS MAY grows well, and is one of the most distinct Roses of the Gloire de Dijon class, but not so lengthy in habit. A pretty opaque pink flower of good shape.

If I had to choose half a dozen from these they would be Beauté Inconstante, Graziella, Crimson Rambler, Clio, Clara Watson, and Alister Stella Gray as being the most distinct, but Marchioness of Downshire and Mrs. S. Crawford are both excellent.

RIDGEWOOD.

#### NOTES ON ROSES.

DOUBTLESS the pages of THE GARDEN will soon be a guide as to the damage done among Roses by the severe frost of January and the present month. How many of us can look at our Roses now without despondency when we not only experience frosts of 20° to 25°, but also have most searching and frost-laden winds. In 1893 we had 29° early in February and 15° about the middle of the month. Not only was this considerably less than that prevailing while I write, but we were also without a keen wind. Those who make a practice of protecting no doubt feel safer than others who do not take this trouble. After all I think the results in spring from over-protection are almost as bad, but I am quite willing to admit that I should prefer my own protected from the terribly keen wind and frost now prevailing. Even the base of our plants and the dormant buds on dwarfs are more fully exposed than usual during an extra sharp frost, because in this locality we have scarcely any snow, not more than an inch. I fear that those who object to spring planting will find themselves forced to it this season if only to fill up blanks in those beds that were autumn planted. New beds can be made as soon as the frost is well out of the ground, but I shall be in no great hurry with our own, preferring to wait until the ground gets a little warmer. Plants in pots, such as grafted Teas and others that were not potted on or did not grow sufficiently strong to occupy 6-inch and 8-inch pots for this season's forcing, will be capital for filling in blanks. We usually store these in a wooden frame or pit, or stand them in a sheltered corner and then cover up, the object being to protect the wood both for late grafting and also so that the plants may come on well when potted up and started for making extra sized specimens in the coming year. This season, however, the bulk of these will be retained for filling the gaps it is quite certain we shall soon discover. Indeed, I see that several plants of Comtesse de Nadaillac are killed down to the ground line, and more mischief may be exposed later on.

At this date I have more than once given a few notes on pruning, but this season it seems likely we shall need to prune all kinds alike by simply cutting away the dead wood. A friend of mine whose rosery is in a low and rather damp spot has often jocularly remarked that King Frost does all of his pruning. The other day he feared this exceptional weather had overdone it, and this more especially among the climbers and extra vigorous sorts of all

classes. Here is the very case where little pruning at this season is necessary, and the results are likely to be severely felt when our summer Roses should be in full bloom. Climbers and strong growers are so dependent upon such wood for their chief display, that we cannot look forward with any degree of confidence.

I had intended to note a few of the worst and a few of the least affected sorts in my collection, but, the frost showing no signs of abating, I will leave it awhile and look them over again. Nor can we possibly form an idea of much value until the frost is well gone and our plants once more try to make growth. We who leave them totally unprotected may have to moderate our ideas of the hardiness of Roses, but one consoling point in favour of our theory is that many, I fear very many, other recognised hardy plants will also succumb.

#### LENTEN ROSES AS CUT FLOWERS.

THE accompanying illustration shows the beauty of the Lenten Rose (*Helleborus orientalis*) when

Flowers of *Helleborus orientalis* in a vase. Engraved for THE GARDEN from a photograph sent by Mr. G. Ingram, Ascot.

arranged in a vase. There is great charm in these lovely spotted late-blooming Hellebores, the colours ranging from greenish white to deep purple rose with rich spottings of darker shades. It may not be generally known that Lenten as well as Christmas Roses will remain fresh in water for a considerable time longer than they otherwise would if the stems be slightly slit at the base for an inch or so upwards. We once thrust bits of pointed stick into the stems of some to add to their height, and were surprised to find that while these not so treated withered after a few days in the water, the others kept quite fresh, although all were in the same bowl, and on examining them we found that the stems had burst. This led us to think that the splitting of the stems allowed them to absorb an extra amount of water. On making further experiments we found that this held good not only with these plants, but also with many other fleshy-stemmed flowers. It often happens that

the stems split without the aid of the knife, but they will not do so if they are cut off quite close to the base.

## ORCHIDS.

### PHAIUS.

THESE are very useful Orchids, many of them thriving in structures devoted to the culture of ordinary stove plants quite as well as in the Orchid house. They are mostly of an ornamental habit, and if in good condition bear fine foliage and large handsome racemes of flower. While growing freely they require for the most part an abundance of heat and moisture, the roots also being kept well supplied. After the pseudo-bulbs are fully matured, the plants must be kept nearly dry in a cooler house until they show signs of breaking into growth, when they should be repotted and again introduced to the stove temperature. They must be grown in fairly large pots in a much more substantial

compost than most Orchids require. Sound fibry loam enriched with a little dried cow manure or some other fertiliser, chopped Sphagnum, a little leaf-mould, and nodules of charcoal or potsherds will be suitable for the strongest growers, as *P. grandifolius*, while for *P. tuberosus* the loam and manure must be left out and peat fibre substituted. The leaves of Phaius are very subject to insect attacks, thrips, red spider, and scale all being extremely troublesome if not kept well in check. Green-fly, too, is an inveterate enemy, appearing yearly upon the spikes when forming, and if not removed soon spoiling them. If the plants are arranged so as the syringe can be freely used around them and over the foliage, this is comparatively easy, but otherwise there must be very frequent syringings and even fumigations in order to keep the plants clean. Propagation is easily effected by division of the pseudo-bulbs at potting time, *P. grandifolius*

being especially amenable to this treatment, throwing up a number of young shoots, any or all of which will if carefully treated make young plants.

*P. BICOLOR* is a native of Ceylon, whence it was introduced in 1837. It is a large-growing species, with narrowish leaves 18 inches in length and large roundish pseudo-bulbs. From the bases of these the flower-spikes spring, and often attain a height of 3 feet. The blossoms are produced successively along the spikes, so that they last a long while in beauty. These are about 4 inches across, varying in colour, but usually some shade of reddish brown. The lip is yellowish in front with a rosy margin, the enfolding lobes being bright rose.

*P. BLUMI* is a fine handsome species, with broadly lanceolate leaves and short, roundish pseudo-bulbs occurring upon the creeping rhizome. The spikes rise to a height of about 3 feet, and bear upon the upper portion many flowers, individually about 3½ inches across. The sepals and petals are brownish or green and the lip yellow, with a large crimson spot under the column. This kind flowers in spring and has several varieties, including Bernaysi, which is lighter in colour than the type, and occasionally classed as a separate species. This comes from Australia, the type being a native of Java. Other varieties are assamica and Sanderiana, both natives of Assam. The well-known

*P. GRANDIFOLIUS* is one of the oldest Orchids in cultivation, having been introduced 100 years ago. It is said to be a common plant in the East Indian and Australasian islands, and also the mainland of China. The flower-spikes are produced from the base of the large leafy pseudo-bulbs, and attain a height of about 3 feet, producing many flowers. These are silvery white outside, chocolate-brown inside the sepals. The lip is white, with a yellow throat, shaded and veined with crimson. It is easily grown, seldom out of health, and flowers from midwinter onwards to the end of April.

*P. HUMBLI* is a rare and beautiful species, at present only represented in good collections. The sepals are narrower than the petals, pale rose, the lip deep rose, becoming nearly white under the column, where there are also two ridges or crests of yellow. This plant requires a strong heat, being found naturally in Madagascar.

*P. MACULATUS* is one of the very few Orchids which have finely variegated foliage, as well as attractive flowers, and which should be grown by everyone. The deep green lanceolate leaves are 4 inches across, thickly spotted with yellow. The flower-spikes grow about 2 feet high, and carry about a dozen flowers, each 2 inches across. These are yellow, with a reddish brown margin to the middle lobe of the lip. This species varies somewhat in colour, the brightest forms being very attractive. A native of Northern India.

*P. TUBERCULOSUS* is quite a distinct species from all the others, and a remarkably beautiful Orchid, which, unfortunately, is not always so happy under cultivation as could be wished. The sepals and petals are pure white, but the lip is the most attractive part of the flower; the upper lobes are canary-yellow, with a number of crimson spots, the front lobe roundish, crimped at the edge, white, spotted with purple and orange-yellow. This species must be planted in well-drained pots and watered freely while growing in the East India house. It must be shaded from bright sunshine and kept free from insects, or good results must not be looked for.

*P. WALLI* is similar in habit to *P. grandifolius*, and flowers at the same season. Like it, the flowers are white externally, yellow flushed with purple inside: the lip is pointed, yellow, with purple about the throat. The flower-spikes last a long while in perfection, and as they grow upwards of a yard in height, it makes a noble-looking plant. This species was introduced from India in 1837.

Besides the foregoing, this genus now contains several choice and rare hybrids, as *P. amabilis*,

raised by the Messrs. Veitch, *P. Cooksoni*, named in compliment to the raiser, *P. hybridus*, and the newer and beautiful *P. Owenianus*, exhibited by Messrs. Sander at the Temple show in 1894. H. R.

**Cypripedium barbatum Warnerianum.**—This species is no doubt one of the most popular kinds we have, having gained much popularity since the time of its introduction—over fifty years ago. The variety here referred to is unquestionably the most highly coloured of all and appears to flower earlier in the season than the typical form. I have recently seen several fine examples in bloom, the dorsal sepal in some instances being very highly coloured.—W. H. G.

**Angræcum fragrans.**—This is a plant that is rarely seen in our collections, although an old introduction. The flowers are borne singly, and each measure about 2 inches in diameter, are pure white, and, as the name implies, are very sweet scented. This also applies to the foliage, and it is stated that the leaves are largely used for imparting a delicious flavour and sweet aroma to ordinary tea when mixed with it; and, in fact, in Mauritius, its native country, a very agreeable preparation is said to be made entirely from the leaves of this plant. Being one of the few Orchids of commercial use, and not appearing to be very widely distributed over the globe, may probably account for its scarcity under cultivation.—G.

**Cypripedium Morganæ.**—This hybrid, although not new, is still one of the finest in the genus. It is remarkable for its perpetual blooming, especially in Messrs. Williams' nursery at Upper Holloway, where there is a good batch of this kind. It is just about fifteen years ago since it first made its appearance, having been raised by Mr. Seden in Messrs. Veitch's nursery at Chelsea between *C. Stonei* and *C. superbium*. This plant, although perfectly distinct, somewhat resembles the very rare *C. Stonei* platytanium, having fine large, spotted, and drooping petals, and the dorsal sepal also resembles that of *C. Stonei*. During the past year there have appeared one or two very beautiful and distinct crosses, with flowers partaking of the same form, but I do not think they are better than this fine kind.—W. H. G.

**Cattleya Percivaliana.**—Several fine forms of this delightful plant are to hand from "J. M." of Manchester, who states that he has had this species in flower in large numbers for the past three months. It is in most instances a very highly coloured *Cattleya*, and one that is exceedingly useful for filling an interval between the flowering of *C. labiata* and *C. Trianae*, but not grown so largely as many other kinds. During the last few years, however, it appears to have gained more favour, in spite of the bad reputation it received soon after its first introduction into this country. The flower labelled No. 1 is of fine form and very deep in colour, the bright crimson markings on the large lip being very rich. Nos. 2, 3, and 4 are also very fine, having lighter sepals and petals and the lip is very heavily frilled. No. 7 is sent under the name of *C. Percivaliana aurea*, and although contrasting greatly with the above, is by no means so showy, the lip being almost entirely orange-yellow and lighter towards the front. The remaining flowers represent good typical forms.—W. H. G.

**Odontoglossum nevadense.**—*O. nevadense* is a very beautiful species which resembles very much in habit and general appearance the more popular *O. crispum*, with which it should be grown. Compared with many other lovely kinds, the number of plants in cultivation is remarkably few, and from this one is apt to infer that this plant must be somewhat scarce in its native home. It is stated that the first consignment consisted only of about four plants, and the first of these to flower was in the celebrated collection of Mr. S. Mendel, of Manchester. No doubt if it was introduced in larger numbers it would speedily become one of our most popular kinds, for the colours of the flowers are very striking, the pure white of the lip forming a pleasing contrast to the dark-

coloured sepals and petals. This plant was originally introduced into European gardens about 1868, when it was sent from Venezuela to M. Linden, then at Ghent, by the well-known collector Gustav Wallis, and remained a very rare plant for a considerable time. Since then, however, it has been introduced in quantities from time to time by various firms, and even in these plants considerable variation of colour is exhibited. It produces a slender nodding scape measuring more than a foot in length, and which will sometimes carry upwards of a dozen fine flowers, individually about 3 inches in diameter. The sepals and petals are similar, spreading, plain, and nearly equal, the latter being rather narrower than the former. These are of a deep cinnamon-brown shade with a narrow border of yellow, and usually with a few longitudinal lines at the base and also one or two transverse bars of the same colour. The lip, however, is finely fringed and terminates in a sharp point, pure white, occasionally pale yellow, and having a few brown spots at the base. It is a very desirable species, well deserving a place in every collection.—W. H. G.

#### DENDROBIUM McCARTHIÆ.

ONE of the most beautiful species in this fine genus is *D. McCarthyæ*, and although somewhat more difficult to manage successfully than many other kinds, it certainly well repays for any little extra attention that may be bestowed upon it. Under cultivation this fine *Dendrobe* appears to bloom at various seasons of the year, although in its natural home the flowers are produced during the month of May, from which it derives its native name of "Mayflower." Coming from the hot climate of the Ceylon forests, it must consequently be placed in strong heat in our houses and suspended close to the glass, so that all the light possible may be obtained, especially during the dull winter months. As the bulbs become matured the plants should be given a slight rest, but I believe it is a mistake to keep these too dry at this period, for being a plant of very slender habit, it is almost sure to suffer if not slightly nourished. In many instances this is no doubt the cause of failure with the culture of this species. I have seen the best results produced by placing the plants in very small baskets or upon blocks of wood, with a very little material around the roots when grown in the former; this should be made very firm, and composed of good fibrous peat and chopped Sphagnum Moss, a little silver sand mixed in being an advantage. Like all other Orchids, it requires thorough drainage, for it enjoys plenty of water during the summer months, and this must not be allowed to remain around the roots, for when once the plant gets into a bad condition it very seldom recovers, or will take a considerable time to restore to health. Place it in fully exposed situations where it can enjoy plenty of sunshine, and shade only in the middle of the day when the sun is exceedingly hot. *D. McCarthyæ* was first discovered about forty years ago, when it was sent to the Royal Gardens, Kew, from Ceylon forests. It is found growing upon the trunks of trees, but even in a natural state it appears to be a short-lived plant, and it is reported to have become already exceedingly rare. It is a slender growing deciduous species with semi-pendulous pseudo-bulbs, which do not attain more than 18 inches to 20 inches in length. These are very distinct, being green, spotted with red, and somewhat swollen at the base. The flowers are produced in short pendulous racemes of about two and three together, and individually measure over 3 inches across. The sepals and petals are of a delicate shade of rosy pink, the lip being of the same colour at the upper portion, with a broad

zone of white between that and a blotch of deep purple at the base. These will continue in full perfection for several weeks, and are very attractive and distinct.

WM. HUGH GOWER.

#### **Cypripedium albo-purpureum superbum.**

—A bloom under this name comes from "N. J." It is certainly a very nice form of the typical plant. This is a hybrid of Veitchian origin between *C. Sehlmi* and *C. Dominii*, and first flowered about the year 1877. The variety *superbum* is not a novelty, I having noticed one several years ago even larger and finer coloured than the bloom to hand. Although the flowers do not catch last long in perfection, they are produced in quantity, and as soon as one is past another opens, until the long spike is quite exhausted.—W. H. G.

**Cool Orchids** (*Hallman, Kensington*).—My correspondent inquires for a list of some half dozen kinds of Orchids for a cool house, but as he does not mention the amount of heat usually maintained it is difficult to advise him, for "cool house" is indeed a very vague term. The following, however, are all very beautiful and desirable plants which succeed well under cool treatment, and for descriptions of which I must refer him to recent numbers of THE GARDEN, where they will be found to be fully described and their individual requirements stated. A good selection may be made from the undermentioned: *Lycaste Skinneri*, very useful for lasting a considerable time in perfection; *Odontoglossum crispum*, one of the finest for cutting; *O. Rossi*, very pretty and free-blooming; *Oncidium tigrinum*, very bright and effective; *Cypripedium insigne*, one of the best of the Lady's Slippers; *Masdevallias* in many varieties, *Disa grandiflora*, a brilliant kind, requiring quite cool treatment, and many others, which, if a small amount of heat can be commanded, will keep the house bright for many months.—W. H. G.

**Trichopilia suavis.**—I am in receipt of a few blooms of this old favourite from "W. M.," Norwich, and amongst them is the ephate variety named *alba*. This latter, however, is a poor flower compared to the typical form, but this is probably due to the state of the plant. I would advise my correspondent to take great care of this piece, for when it becomes stronger and better established the flowers should be equally as large as the others, which are very nicely spotted with light rose. This useful and free-flowering plant is of easy culture, and when in bloom gives out a very delightful fragrance, perfuming the whole house. It is a native of Costa Rica, and grows at considerable elevation upon the mountains. Under cultivation it should be grown in quite a cool temperature and kept almost dry whilst at rest. When repotting, care must be taken to raise the plants well up upon a cone-like mound, for the flower-spikes proceed from the base of the bulbs and hang over the sides of the pots or pans. If not able to have a free course, they will quickly commence to decay as soon as they appear should the water remain around them.—W. H. G.

**Saccolabium bellinum.**—This is a useful and pretty little species, and being of a dwarf habit and very free in producing its blooms finds especial favour with Orchid growers. It was introduced by Messrs. Low and Co. through their collector, Mr. Boxall, from Burmah, and its handsome flowers at once attracted attention. The plant does not attain more than a few inches in height, and the thick bilobed leaves generally measure 9 inches or 10 inches long; therefore it is a very suitable plant for establishments where space is limited. The flowers, although small, are produced in a crowded raceme and are borne on short pendent stems. The incurved sepals and petals are very similar, light yellow blotched with deep purple: the lip is white and with a few small spots of red. This little species is one of the most beautiful in the genus, and no doubt the best known of all the kinds belonging to this dwarf section. To grow this plant, strong heat and

plenty of moisture in the atmosphere are needed, as its native habitat is one of the hottest in the world.—W. H. G.

## KITCHEN GARDEN.

### PICKLING CABBAGES.

THESE are not grown in some gardens, as so few are required. The crop is often overlooked entirely, but in a garden of any size it is well to grow every kind of vegetable likely to be useful. There are only about half-a-dozen kinds, the one illustrated, namely, Blood Red, being one of the best, both as regards size, colour and quality. Some kinds have far too much thick stalk, but the one named above partakes of the character of the Drumhead or flat-headed type. It is also known under the name of Large Blood Red, and is grown in large quantities for the market. On the Continent the Red Cabbage is used in a variety of ways, but in this country its value is for pickling. The old Red Dutch is the variety grown in private gardens. It was largely planted in market gardens twenty years

should there be a failure of other kinds which require a longer time to mature.

I will conclude my selection of varieties with a very dark kind named Late Black or Superfine Black, but I do not recommend it in preference to those named above. Though darker in colour when pickled, it loses its colour quickly and is somewhat inferior in quality. There are other kinds, such as the new Garfield Pickler, an early red kind with a conical growth much resembling the well-known Cocoa-nut Cabbage. This when pickled is of a bright red colour and of excellent quality. It should be selected where quality is considered, and with pickling varieties colour is an important point.

As regards culture, so much depends upon the quality. If large heads are required, it is well to sow seed either the last week in July or the first week in August, but much depends upon the soil and locality. The ground should be well prepared for the seed bed, but as only a small quantity is often required, a space may often be given by the side of the other autumn or green varieties. Sow thinly to get sturdy plants. When the seedlings have attained a good size, plant out the end of September in rows at least 2 feet apart and 18 inches between

*Cabbage Blood Red Pickling.* From a photograph sent by Mr. Norman Blake, Bedford.

ago, but I prefer the one illustrated, as less of it is wasted when cut up for pickling.

The next large variety is Large Drumhead, which is a splendid market Cabbage for size and weight, but in quality is not equal to the kinds named, as in wet seasons on some soils it splits so quickly that it is unsaleable. It also gets of a greenish hue or bronzy green if grown in unsuitable soil. Sutton's Dwarf Red is quite distinct from the varieties named above, and is doubtless a choice selection, one of its parents being the one illustrated. It is a dwarfier grower, very solid, and one of the best for a private garden, owing to its delicate flavour. It is the earliest pickling Cabbage I have grown, which is a great gain where ground is scarce. I have obtained very fine heads from seed sown early in March, but, of course, if size be required it is best to sow seed in the autumn. The old Utrecht Red, a small, but very fine dark red variety, is much grown on the Continent. It is recommended for its good quality and value for spring sowing. Sow the seed in March, and pickling may be done late in July, so that it possesses great value as a catch crop

the plants. Cabbages of any kind are gross feeders, liking a rich, well-manured soil, as quick growth in the spring and summer are important. Plant, too, on land that has not borne a similar crop for some time, the ground being double dug or trenched and manured. Firm planting is essential to promote a dwarf stem, and in dry weather give ample supplies of moisture. Those who do not require size may sow seed in March, and they will get small compact heads. Much time, however, may be saved by sowing a pinch of seed in heat in a house or frame and pricking off when large enough into cold frames. Plant out in the middle of April, and this sowing will be weeks in advance of those sown in the open. For spring sowing select a form of the Dwarf Red or Utrecht type, as they come more quickly. To obtain size in either spring or autumn sown plants, the latter during the summer well repay for supplies of liquid manure or guano. G. WYTHES.

**New Onions.**—With the time for sowing close at hand the remarks of several correspondents as to the keeping properties of the various varieties

of Onions are exceedingly well timed. I had a couple of new varieties on trial last year, growing them under ordinary conditions with the old favourites that have served me well for several years—a good type of White Spanish, Giant Zittau, and Brown Globe. Taking them on the average, the novelties were in no way superior either in size or weight of bulb, and their keeping properties may be judged from the fact that it was found necessary to use them before White Spanish was touched. The few that remained had bolted some time before Christmas. As we know that most sorts can be grown to an exceptional size in rich ground and by the liberal use of stimulants, it would be interesting to know if bad keeping is the result of seed-saving from these giants, and if so, wherein lies the advantage of the system of such feeding. For the sake of having two and three-pound bulbs for the show table it is advisable to perpetuate a race that are past their best by the end of the year. In the matter of sowing indoors and transplanting instead of open-air sowing, which is recommended for the general crop as well as for the production of sensational bulbs, has it been proved that this treatment is instrumental in warding off the attack of the fly through the more advanced state of the grass? That the attack of the Onion fly is more a question of locality than of the absence of cultural skill is apparent from the fact that in two gardens almost side by side, where the treatment is identical, the one Onion bed shall be healthy and vigorous, the other almost a total failure.—E. B. C.

**Dwarf French Bean Mohawk.**—This is invaluable for raising in pots and planting out on a warm border sheltered with hand-glasses or frames. I prefer this to many of the others on account of its earliness. A few seasons ago I tried some half-dozen early kinds to test their early cropping character, and Mohawk, or Six Weeks, as it is often named, was six to ten days before any other variety. This variety is above the usual size, and the beans are speckled with purple, very fleshy, and the growth compact, whilst their quality is first-rate. For first sowing in the open I do not know of any better variety if size, earliness, and freedom of cropping be considered. There is often only a scanty supply of vegetables towards the end of May, especially of choice kinds, so that if a good supply of Beans can be obtained by sowing in 4½-inch pots early in March and planting out under hand-glasses when ready, there will be nice dishes at that date and early in June. If cold frames can be spared there is even less trouble in their culture, but I have obtained heavy crops by raising the plants in heat, transferring when above the soil to frames, and planting on a sloping border in front of warm fruit houses protected with spare frame lights, hand-glasses, and mats.—G. WYTHES.

**Veitch's Improved Long-pod Bean.**—Of late years there has been great improvement in this class of Beans. We have secured greater length of pod without that thick shell or woolly matter. The best cropping variety I grew last year was Veitch's Improved Long-pod Bean. It bears freely in light soils, and is equally as hardy as any of the smaller kinds, and in my opinion as regards quality better than many. I do not know of any kind more prolific or more vigorous, and each pod contains five or six beans, which are of a delicious flavour when cooked. The great drawback with many of the large-podded varieties is their lateness, but this is quite as early as any of the small so-called early forms, and being a greater cropper is a desirable variety. From its appearance I should say it is a large early green Long-pod selection, and those who only grow one or two varieties will find this useful in every way.—G. W.

**Notes on Cauliflowers.**—With the thermometer down to zero several nights in succession great havoc has been wrought amongst the Broccoli, and it is certain that a large quantity are completely killed, and probably many more will succumb later on. Cauliflowers in cold frames, although protected by mats, &c., look in a miser-

able condition, and I think will be of little service; consequently, special efforts will have to be made to meet the demand for this vegetable by raising plants in heat and doing all that we can to secure an early supply. The selection of varieties is of some considerable importance, as by sowing extra early sorts and giving them every attention good and fair-sized Cauliflowers can be cut in twelve weeks from time of sowing. So far I have found no variety equal to Carter's Defiance Extra Early Forcing for sowing under glass; the plants are strong, dwarf and well-shaped, of nice size, just the thing for a gentleman's table, and is altogether a variety that I can confidently recommend for very early work. Sutton's First Crop is another most excellent early or mid-season variety, rather larger than the last named, but not so early. Sown at the same time and given exactly the same treatment, it was eight days later in coming into use; however, it forms a grand successor to that variety, and is a good summer Cauliflower as well. For keeping up the supply until Autumn Giant is fit to cut I always rely on a good strain of Early London, and which has never disappointed me in hot or cold seasons, always producing medium-sized heads of excellent quality. At various times I have tried late Cauliflowers against Veitch's Autumn Giant, but have yet to find a variety that will equal that sterling sort through good and bad seasons alike. Beyond question it has proved a great boon to the whole gardening community, and it is doubtful if it will ever be equalled, much less surpassed, in its season.—W. G. C.

**Ne Plus Ultra Cucumber.**—This Cucumber is well known in some parts of Gloucestershire, Worcestershire and Herefordshire, and, I believe, originated amongst the Cheltenham market growers. The fruits are about 14 inches long, of a green colour, and more freely produced than in any variety I have ever seen. Under the high pressure system of giving no ventilation and affording ample atmospheric moisture, with liberal root feeding, it will continue bearing in a remarkable manner for months. For either home consumption or market this variety is well worth a trial, and I believe that once grown its cultivation will be extended. I should also add that it is not only of value as a summer variety, but also for winter work, as excellent crops are produced during the most trying months of the year in a temperature ranging on the average about 60°. Probably some of the well-known Worcester or Gloucester seed-men would be able to supply the seed.—W. G. C.

#### EARLY BROAD BEANS.

Most vegetables will be later than usual if means are not taken to forward the crop, as it will be some little time before the soil is in condition to receive seeds of any kind, being cold and wet after the frost disappears. To get a few early Beans is a simple matter; few vegetables plant out better if some soil is attached to each lot of plants. Those who have no room for pots may sow thinly in shallow boxes in rich soil, placing the boxes on warm pipes or flues till the seeds have germinated. When the tops are a couple of inches above the soil, remove the plants to a lighter, cooler place till ready to plant. Cold frames answer well after the plants attain a few inches of growth, as in such they are near the light and well hardened by removal of the lights in fine weather. The other method of raising plants by sowing four to six Beans in a 4½-inch pot is equally good, and there is less fear of the balls being broken at planting time. I do not like, however, the plants to get too much pot-bound, as they do not grow away so readily when planted. If a mass of roots, the lower portion of the ball should be opened out for the roots to lay hold of the soil, otherwise they suffer from drought and are a prey to black-fly. There are other means of raising a crop, but those named are best where time is a consideration. In planting out the Beans raised as advised it is well to

draw deep drills, and as each lot of plants is placed in the ground to put some rich soil, such as from Cucumber or Melon beds, around the roots. Make this firm, and draw some soil to the side of the rows. I have also sheltered with branches of Fir or Yew for a time, and with care the plants will give a supply weeks in advance of those sown in the open, and being very dwarf may be planted at 2 feet to 3 feet apart in the rows. As regards variety, it was always considered best to plant Early Mazagan for early use, but it is not the earliest and the beans are very small. The Early Long-pod is better in every way. The chief points to be observed in growing Broad Beans for a time under glass is to harden the plants well and not crowd at starting. Plant with a ball, and give water in dry weather.

G. WYTHES.

## TREES AND SHRUBS.

### FLOWERING TREES AND SHRUBS.\*

WITHIN the limits of half an hour it is manifestly impossible to do more than call attention to some of the less known trees and shrubs which can be grown in the open air in this country. A mere list of names could be drawn up which would occupy most of the time at my disposal, but such a list—though perhaps useful for purposes of reference—would be very tiresome to read, and much more tedious to listen to. I shall therefore confine myself for the most part to ornamental trees and shrubs which, in my opinion, are well worthy of much more extended cultivation than they now enjoy. Unless specially singled out for comment in the way of hardiness, it may be taken for granted that the plants are hardy in the neighbourhood of London and in the south of England generally. In all probability a large proportion would prove hardy much farther north, but I have not sufficient data to enable me to speak with certainty as to the behaviour of many of them except at Kew and in the neighbourhood of London. The mere omission, therefore, of numbers of very beautiful trees and shrubs must not be taken to mean that the ones mentioned in this paper are superior in any way to those not mentioned. More than half an hour could be profitably employed in a review of garden Roses—not Hybrid Perpetuals, Teas, and so on, but simply of the wild species, botanical varieties, and little-known hybrids.

After these remarks I proceed with the paper, merely stating that I take the natural orders in botanical sequence for the sake of convenience.

The Magnolia family contains a number of the most beautiful flowering trees and shrubs in existence. Fortunately most of these are pretty well known, but the following Japanese species are recent arrivals in this country, and therefore not known to the vast majority of gardeners. *M. Watsoni* and *M. parviflora* are both very handsome plants, and, thanks to Messrs. Veitch, they have been introduced in considerable numbers; this firm exhibited flowers of both at the Temple show. *M. hypoleuca* is a fairly fast growing tree with noble leaves and showy white flowers. *M. compressa*, an evergreen species from Japan, has withstood at Kew, without being in the slightest degree affected by the cold, the rigours of the past winter (1893-4), and bids fair to be an acquisition. Visitors to the meeting held in this building more than a month ago will remember a very strange and abnormal member of the Magnolia family, a basket of cut shoots of which was exhibited by Messrs. Veitch. I refer to *Trochodendron aralioides*, figured in the *Gardener's Chronicle*, an evergreen shrub with the twigs terminated by panicles or clusters of green flowers. This, like the Magnolias above named, is also Japanese.

The Berberis family contains but one genus of woody plants which is deserving of general re-

\* Paper read at a meeting of the Royal Horticultural Society by Geo. Nicholson, June 12, 1894.

commendation. The following species of Berberis are well worth growing, even in select collections of flowering trees and shrubs. *B. angulosa* and *B. coccinea* are both Himalayan; the former has rather large golden yellow flowers, produced singly from the axils of the leaves, and the latter is conspicuous on account of the silvery white of the lower surfaces of its small leaves. *B. congestiflora* is a Chilean plant introduced to cultivation by Messrs. Veitch, and figured some few years ago in the *Botanical Magazine* and in the horticultural periodicals; when developed, the long shoots, densely clothed with golden yellow flowers, make this a most desirable and very ornamental plant. *B. actinantha* is another Chilean species almost as handsome, when well grown, as the favourite *B. Darwini*.

The family Bixineæ is principally a tropical one, but the two genera *Idesia* and *Azara* are worth mention in this paper. *Idesia polycarpa* is a Japanese tree of considerable stature in its native country. In England it does not appear to be long-lived, but it is worth growing on account of its handsome foliage and the pendulous panicles of yellow male flowers. The tree is dioecious (the female flowers are green), but are followed by enormous numbers of small orange-coloured fruits as large as Peas. Like hosts of plants which are generally regarded as hardy, this is somewhat tender in a young state, but if sheltered for a few years it appears to be able afterwards to dispense altogether with protection. I have seen large trees in Northern Italy in places where the winter cold is more severe than with us. Several of the Azaras make charming wall plants; perhaps the hardest is *A. microphylla*, introduced from Chili by Messrs. Veitch. The habit of this is very graceful, and its small fragrant yellow flowers are produced in great profusion on established plants; it should be planted in sheltered places. It would be interesting to know how this species has fared at Belvoir Castle since April, 1890, when the late Mr. W. Ingram read his paper on "Spring Flower Gardening." He says: "I should like to call special attention to that very handsome evergreen, *Azara microphylla*. It is now (at the beginning of April) in full bloom, but it makes its presence felt not by the attractive characters of its flowers, but by the wonderful fragrance they exhale. The garden is filled with an aroma resembling vanilla."

The Camellia family (Ternstroemiaceæ) furnishes us with the genus *Stuartia*, surely one of the most ornamental genera in cultivation. The Japanese *S. pseudo-Camellia* has been exhibited frequently before the R.H.S., and the North American *S. virginica* and *S. pentagyna* are two of the most beautiful plants I know. Those who are familiar with the fine bush of *S. virginica* at Syon House do not need to be stimulated by any word of praise of this plant.

The Mallow family contains, in addition to *Hibiscus syriacus*, which is too well known to need further mention, perhaps only one species of woody plants thoroughly worth growing. I allude to the New Zealand *Plagianthus Lyalli*, a hardy shrub or small tree with large Cherry-like blossoms; it makes an excellent wall plant at Kew, but grows in the open, and is not injured by frost.

*Fremontia californica* is the only member of the order Sterculiaceæ which calls for notice here. In this country it seems to be very short-lived, but the beauty of its flowers renders it worthy of a place on a wall, where it blossoms profusely. I have seen it thriving well as a bush in the open. It would be interesting to learn particulars of the oldest plants now in cultivation.

The Rue family does not furnish us with many hardy shrubs. *Choisya ternata*, well known as a delightful wall plant and an excellent subject for cultivation in pots, is somewhat tender in a young state, but sheltering during severe weather for a couple of years or so enables the plant to withstand afterwards our ordinary winters without protection in the open. Under such conditions we have had the plant thriving and flowering freely as a bush at Kew. *Skimmias* are worthy of mention. The true *S. japonica* (formerly known under the name of *S. oblata*) is one of the best of

all evergreens for smoky grounds; attention has been called to its value in this respect by Dr. Masters. *Pseudagale sepaiaria*, or *Citrus trifoliata*, is nearly allied to the Orange. In the south of England this is quite hardy. The Rev. Canon Ellacombe, in his charming garden at Bitton, has a plant which has fruited; in the neighbourhood of London the plant flowers freely in the open, but does not fruit.

From the Buckthorn family we may select the Christ's Thorn (*Paliurus aculeatus*), a pretty bush or small tree, hardy in the neighbourhood of London. The buckler-shaped fruit is curious. *Ceanothus* is worthy of special mention. Many of the species are too tender for our climate unless they are cultivated as wall plants, but the wealth of flowers and their colour make them desirable garden plants. *C. rigidus* was a sheet of blue a month or more ago at Kew; at present *C. papillosus*, exhibited to-day, is a worthy successor. Neither can be depended upon as bush plants near London. *C. americanus* makes charming masses of delicate flowers, white or white tinged with bluish colour; this only grows about 2 feet high, and at Kew succeeds perfectly in the open. Some of the garden forms or hybrids derived from *C. azureus* make fine bushes, and flower profusely in the open. *Gloire de Versailles* and *Marie Simon* are two of the best. *Rhamnus libanoticus* is conspicuous by reason of its handsome foliage, which assumes a rich bronzy colour in autumn.

The Vine family is well known as supplying us with some of the most beautiful hardy climbers. *Vitis Coignetii* is the only species which I have space to mention here. The flowers are sweet-scented, and the colours assumed by the decaying leaves in autumn are brilliant in the extreme. Those who have seen this Japanese climber in Mr. Anthony Waterer's nursery at Knap Hill, rambling over the trees in its neighbourhood, are not likely to require any persuasion to make them endeavour to procure it for their own gardens.

The Horse Chestnut family (Sapindaceæ) is an important one from a garden point of view. *Koelreuteria paniculata*, from North China, is not nearly so much grown as it deserves to be; its pinnate leaves, erect panicles of yellowish flowers, followed—in favourable seasons—by large bladder-like fruits, make it a conspicuous object in the shrubbery or park, and the decaying leaves in autumn assume a rich red-brown tint. Very recently a new species has been discovered and introduced from South China through the agency of the French missionaries; but it is too early yet to speak of its value in hardy out-door gardening in this country. The Chestnuts deserve special mention—one in particular, *Esculus rubicunda* var. *Brioti*, a form having flowers about three shades deeper in colour than the ordinary Red Chestnut. *E. indica*, figured as long ago as the year 1858 in the *Botanical Magazine*, t. 5117, from specimens from Mildenhall, in Suffolk, is scarcely known in gardens, although it is a handsome species. The Japanese *E. turbinata* is also almost unknown in British gardens. *E. californica* makes a small compact tree; it has glossy leaves and dense panicles of rather small yellowish-white or flesh-coloured flowers. *Xanthoeris sorbifolia*—generally grown against a wall, and still rare in gardens—is quite hardy in the open, although it does not grow so fast as when trained against a wall. It is a Chinese tree, and likes a sunny, open place. The finest tree I have seen is in the famous arboretum at Segrez formed by the late Mons. Alphonse Lavallée.

In the Pea family there is a large number of excellent garden plants. I can only venture here to give a selection of those members which are least frequently seen in gardens. One of the handsomest species in the genus *Genista* is *G. virgata*, which is hardy enough at Kew, many large bushes having withstood probably more than thirty winters in that establishment. Every summer it is laden with a profusion of golden yellow flowers. *G. atnensis*, a South European species, has pendulous leafless twigs when the plants are old, and when in flower the tree (for it really makes a small tree) looks like a golden fountain. *G. germanica*, a charming

little bush a foot or so high, is well worth growing, and in its way is as good as the better-known *G. hispanica*. *Cytisus Ardoini*, a native of the Maritime Alps, is a handsome species only a few inches high; in late spring it forms a carpet of deep yellow flowers. *C. purpureus*—one of the parents of the purple *Laburnum*, *L. Adami*—is a beautiful free-flowering dwarf bush, and its purple blossoms render it conspicuous in a genus where the vast majority of the species have yellow flowers; there are white and bluish-coloured varieties of this. The purple *Cytisus* is much longer-lived if grown on its own roots than when grafted, and apparently even grows more freely under these conditions. *C. purgans*, a compact South European bush, has golden yellow flowers; it is one of the parents of the so-called *Genista præcox*, the other being the white Spanish Broom (*Cytisus albus*).

Amongst the Rest Harrows, or Ononis, we have *O. arragonensis*, a bush a couple of feet or so in height, laden with erect racemes of yellow flowers. This seems to be a comparatively recent introduction to British gardens, and, judging by the Kew experience of some half-dozen years, it appears to be quite hardy enough to withstand the winters near London. *O. fruticosa* is a good companion plant to the last-named; it has rosy-purple or pinkish flowers. *Amorpha canescens*, the "Lead plant" of the United States, is a beautiful species with grey-green leaves and panicles of blue flowers. In nurseries a comparatively worthless plant, a form of *A. fruticosa*, passes under the name of *A. canescens*. *Indigofera Gerardiana*, a Himalayan species, grown in some gardens as *I. Dosua* and in others as *I. coronillaefolia*, makes a handsome wall plant, and also does well in the open; under the last-named conditions, however, it sometimes gets damaged by frost, but springs up rapidly from the root and flowers freely. The Rose Acacia (*Robinia hispida*) is almost always met with grafted on the common Locust; on its own roots it is much more effective and longer lived, and the very brittle branches are less likely to be injured by strong winds. *Halimodendron argenteum*, the so-called Salt tree, a native of Asiatic Russia, does well in sandy soil, but likes all the sun it can get; the foliage is silvery and the flowers purplish-pink in colour. This species does well near the sea. *Hedysarum multijugum*, from Central Asia, &c., is showy enough with its pinnate leaves and long axillary racemes of bright red flowers; it is, moreover, perfectly hardy. *Cesalpinia japonica* is interesting as being perhaps the only hardy member of a handsome genus, the others being tropical in their requirements. It is an introduction of Messrs. Veitch, and is worthy of cultivation.

Any attempt to give an exhaustive *résumé* of the good things in the order Rosaceæ would end in ignominious failure; all I can do is to mention as briefly as possible a few species of the Rose family which are not so often seen as they deserve to be. The first to flower is *Prunus Davidiana* or *Amygdalus Davidiana*, a Chinese Almond which opens its flowers in favourable seasons as early as the end of January; this year at Kew our trees were in fine flower in mid-February. *P. Mume*, a Japanese species with numerous varieties, is also an early flowerer. *P. divaricata*, from the Caucasus, Afghanistan, &c., forms a snowy sheet of blossom long before the leaves appear. In this country it fruits seldom; on the Continent, however, I have seen the beautiful Cherry-like fruits produced in great profusion. *P. pendula*, from Japan, is considered by Professor Sargent to be one of the floral treasures of the world, one of the very best garden plants ever introduced. The habit of the tree, too, is remarkably good, the pendulous branches laden with rose-coloured flowers giving it a fountain-like aspect. *P. prostrata* is a dwarf bush from Persia, &c.; it has small leaves and rosy-red flowers produced before the leaves are fully developed.

Of *P. pumila* there are many forms varying greatly in habit. This plant has a wide distribution in North America and is perfectly hardy. One variety is prostrate; another dwarf, say 1½

feet high; another 4 feet or more in height, and so on. All bear an abundance of white flowers and are quite hardy. *P. japonica* or *P. sinensis* is one of the most charming dwarf deciduous shrubs we possess; it should be grown on its own roots—grafted on Plum stock it soon becomes unsightly and goes off. The double white form is preferable to the reddish-tinted one, and is a more profuse flowerer. *P. triloba*, also from Japan, &c., should also be grown on its own roots; it, too, is perfectly hardy, although as a wall tree it makes one of the most beautiful trees we possess. *P. nana* or *Amygdalus nana*, a native of Southern Russia, &c., is a delightful plant, and also quite hardy.

*Nuttallia cerasiformis* flowers very early in the year, when few things are in blossom in the open air; it is a native of California, and perfectly hardy in this country. I have not seen the Damsion-like fruits produced in Britain, but on the Continent it frequently ripens fruit. Of the *Spiræas* I have only space to mention a few. *S. arguta*, a plant of hybrid origin, a creation of the gardener's art, is an early-flowering kind, one of the very best; in spring it forms a snowy sheet of blossom. *S. bracteata*, introduced from Japan by Siebold, is still comparatively but little known. *S. decumbens*, a native of the Tyrolean Alps, is a pretty rock plant; it grows about 6 inches in height and bears a profusion of white flowers about midsummer. *S. dasyantha*, a Chinese species, is also worth a place even in the most select collection; it has heads of large showy snow-white flowers. *Stephanandra flexuosa*, though the flowers individually are inconspicuous, is a graceful deciduous bush with beautiful foliage. *Exochorda grandiflora*, from China, perhaps does best as a wall plant, although it is perfectly hardy—the large snowy-white flowers not being so likely to be injured by the cold of our English springs. *E. Alberti* is a Central Asian plant of much more recent introduction. *Eucryphia pinnatifolia* is one of the numerous fine shrubs introduced from Chili by Messrs. Veitch; in the neighbourhood of London, at any rate, it is quite hardy. A beautiful shrub is *Rubus deliciosus*, with large white Rose-like flowers; it is a native of the Rocky Mountains, is perfectly hardy, and does best in a good stiff loamy or clayey soil; in light sandy spots it does not assume its true character, and is not satisfactory. The Roses, the single ones, species or first crosses, would supply abundant materials for a paper, simply treating them from a purely gardening standpoint. A fortnight ago *R. lutescens*, with its large creamy-yellow flowers, was a mass of flower at Kew. *R. microphylla*, a native of India, is exhibited to-day; it has peculiar spiny fruits, which when ripe exhale an odour somewhat resembling that of the Pine-apple. *R. macrophylla* is another Indian species, a tall-growing bush with long leaves and red flowers, followed by peculiar long fruits. *R. sericea*, also from India, is not nearly so well known as it should be; its white flowers are produced abundantly in the open and the bush is quite hardy. One peculiarity deserving of mention in this species is the fact of its very frequently having only four petals. As it is not mentioned in Mr. Webster's useful little book, "Hardy Ornamental Flowering Trees and Shrubs," a book which nevertheless contains a considerable number of little-known plants, I presume it is even less known than I at first thought. *R. arkansana* is distinct in colouring and a profuse flowerer; it makes a bush 6 feet or 8 feet in height. *R. involuta* var. *Wilsoni*, from the Menai Straits, and *R. hibernica* are two of our native British Roses which are worth a place in the garden, the former on account of the beauty of its rosy-red flowers, and the latter on account of its compact habit, glaucous leaves, white or flesh-tinted flowers, and handsome fruits.

Of the Thorns and Crabs I have no time to speak. I venture to suggest, however, that much good work might be done if gardeners and nurserymen exhibited fruiting branches of these during the autumn meetings of the society. The Cotoneasters are, most of them, not only very ornamental when in flower, but still more ornamental when in fruit. *C. frigida* has large corymbs of white

flowers followed by scarlet berries, and *C. bacillaris* white flowers and black or purple-black fruits. *C. horizontalis*—like the two species already mentioned, a native of the Himalayan region—is very distinct in habit, the branches being arranged in a distichous manner; the flowers, particularly when in bud, are reddish tinted. *Pyrus arbutifolia* and *P. nigra* are pretty dwarf shrubs with white flowers; the first has red fruits, and ripens late in the season, the other black fruits, ripening early. The foliage of both assumes a rich red colour in autumn.

The Saxifrage family is rich in garden plants. The genus *Deutzia* is well known, but a recently introduced Japanese species, *D. parviflora*, is scarcely known as yet in this country. It is a perfectly hardy shrub, and one of the best of a genus all of which are desirable plants. The genus *Philadelphus* contains a number of most useful flowering shrubs. I mention specially *P. microphyllus*, a Western North American dwarf shrub, with small white flowers; it comes in very useful in places where there is not sufficient space for the taller-growing species. *M. Lemoine*, of Nancy, has raised a number of hybrids between this and *P. coronarius*, the Mock Orange, and these also are really excellent garden plants. The Rocky Mountain *Jumescia americana* is worth growing; it is a dwarf bush, free flowering, and perfectly hardy. *Carpenteria californica*, a handsome shrub with large *Philadelphus*-like flowers, is generally grown against a wall; it, however, thrives as a bush in the open shrubbery. Of all the *Escalonnias*, *E. Philippiana* is the hardiest in the neighbourhood of London; it is a compact grower, and produces an abundance of white flowers. *Itea virginica* is hardly enough, but likes a strong loamy or clayey soil; it only grows about a couple of feet in height, and its terminal erect racemes of white flowers are very showy. This plant, too, is worth growing, if only for the beautiful autumnal tints assumed by the decaying leaves.

## THE ROCK GARDEN.

### III.

FEBRUARY 11.—Since my last notes on the rock garden relating to winter effects and early blooming hardy plants we have had in the western counties a continuous spell of cold weather of exceptional severity. The ground for the most part is covered with several inches of snow, and cold easterly winds accompanied by a temperature varying from 6° to 22° of frost have been the order of the day during the last fortnight. Most of the smaller rock plants mentioned in my previous notes are buried beneath a hard crust of frozen snow, and, with the exception of rock shrubs, only such plants are visible as are occupying abruptly sloping ground where the snow could not settle. The continuous hard frost has bronzed the foliage of many plants which do not generally lose their bright green colour during winter. In the foliage of *Saxifraga tridactylites*, for instance, I do not remember having previously seen such a decided change from green to bronze, and *Gentiana verna* is quite of a reddish hue at present.

Flowers among the rocks under such exceptional circumstances as regards the weather are, of course, quite out of the question this week, but on looking over various rock gardens one cannot help noting the effect of dwarf shrubs introduced here and there for the sake of giving greater prominence, especially to elevated portions, where special provisions have been made to keep the roots of the rock shrubs away from the smallest and choicest alpenes. Among such dwarf shrubs, which are handsome even now, though the snow is covering the ground, I will mention a few of the most striking.

*Azalea amena*, whose flowers are not due for several months to come, is, nevertheless, very ornamental just now, owing to its

compact habit of growth and irregular mode of branching. The same might be said of the alpine *Rhododendrons*, *R. ferrugineum* and *R. hirsutum*. Several kinds of shrubby *Veronicas*, too, are very effective winter ornaments. In Messrs. Veitch's rockwork at Exeter four of these were planted side by side about three years ago, and it is interesting to note their relative progress. *Veronica Colensoi*, which flowers late in the season, has made a compact little bush about 1 foot through, and its bright green glossy leaves are very conspicuous just now. *Veronica salicoides* is still only about 3 inches high and perhaps 10 inches in diameter, which proves the exceedingly slow growth of this variety; the foliage is of a yellowish green tint, and resembles more that of some *Lycopod* than a *Veronica*. *Veronica cypripedoides* planted at the same time is now about 1 foot in height, and might well be mistaken for a conifer. *Veronica pinguifolia* by the side of it has formed a spreading bush, covering several square feet with its prostrate stems and glaucous foliage, which hanging over the stones are very effective.

Another rock shrub of prostrate habit and of effective appearance even during this cold weather is *Arbutus Uva-ursi*, which grows downwards over rocks and soil, and is well adapted for covering stony banks. Peculiarly striking, too, is *Hedera conglomerata*, the only Ivy which I think should be used in a rock garden that contains small alpenes, which would soon be killed by fast-growing kinds of Ivy. I have just seen a specimen of *Hedera conglomerata* which was planted nine years ago, and is now a bush scarcely more than a yard in diameter and about 15 inches high. Instead of clinging to soil or stones the branches turn upwards, and are densely clothed with compact masses of foliage. Among the rock shrubs which are handsome at the present cold season I may also mention *Raphiolepis ovata*, which has not suffered in the slightest degree from the effects of the continuous frosts we have had lately. The plant in question is growing among stones covered by a woolly carpet of *Thymus lanuginosa*; it was planted about ten years ago, and forms a handsome bush about 2½ feet high and 4 feet in diameter. It flowers every year, but its ovate, thick leathery leaves give it an ornamental appearance all the year round.

The severe weather has left its mark on several of the larger kinds of plants forming a background to the rock garden. *Carpenteria californica*, for instance, has quite a shrivelled appearance owing to its leaves being curled up by the sharp frost, but as the same plant stood 22° of frost during a previous winter without any protection, its leaves will probably expand again as soon as the weather breaks up. *Fremontia californica* also appears to have suffered a little, but though its foliage has become brown, the buds appear to be green and healthy. Another rare plant, *Eucryphia pinnatifolia*, does not seem in the least affected by the continuous severe frost, and is already showing its fresh, green buds quite 1 inch in length. *Magnolia stellata* is densely covered with flower buds, and promises to look better than ever in spite of the hard weather.

A fine specimen of *Romneya Coulteri* retained its green leaves in perfect freshness until the beginning of January, but since we had 20° of frost all stems and leaves are withered to the ground. As, however, the plant is well established, this probably will not affect it, and the withered stems and leaves will afford shelter to the young crowns below the ground.

Enter.

F. W. MEYER.

(To be continued.)

## NOTES OF THE WEEK.

**Galanthus cassaba**, two years established, is now in flower, showing above the snow: it certainly gains in strength and beauty, and is going to be one of our best and hardiest kinds.—T. SMITH.

**Marettia bicolor on an open wall.**—I saw this plant during the month of October last growing luxuriantly and flowering in the freest possible manner on an open wall in a garden near Bray, where it had been for two years at least, apparently happier than I ever remember to have seen it under glass.—T. SMITH.

**Puschkinia scilloides.**—There was a note in this plant in a recent issue having reference to the fondness of slugs for it. I wonder if by *P. scilloides* *P. libanotica* is meant? There is not so very much difference apparently between these two bulbs. The latter, however, is very plentiful, while the former is scarce.—T. SMITH.

**Anthracite coal.**—With the thermometer a few feet away at the time of writing registering 24° of frost, it is a comfort to feel that all the houses being forced are perfectly safe, and a correct temperature in each through the use of anthracite. After using it for many years, I can recommend it as a boon to gardeners and economical to their employers, as though it may cost more than the ordinary fuel at first, it more than counterbalances that by the time it burns without replenishing or other attention, and also being smokeless, it is no nuisance if the gardens are close to the mansion.—W. G. C.

**Iris Historic.** The extreme hardness of some hardy plants is well shown in the case of this Iris. In a nook looking east is a colony with one flower open and numerous buds in various stages of expansion. The ground is as hard as iron. There is a little sunshine most days, which, of course, they get the benefit of, but which is not enough even to thaw the surface. How under such conditions this charming bulb continues to make progress from day to day is an utter mystery. One would imagine it should have been melted into pulp instead, but it looks bold and happy quite as though it liked it.—T. SMITH.

**Sarracenia purpurea.**—A number of plants of this in pots standing just below the water surface of an open air tank have been fully exposed to all the terrible frosts we have lately had. In many cases the pots are smashed from around them: in most of the others the soil and plant have been lifted up half way out of the pots. I know it comes from a region where frosts are more severe than anything we experience here: still, a plant in nature, more or less protected by herbage and snow, is much more favourably situated than are those described above. If they come through all right I think we may safely call it a hardy plant: at any rate I will let the readers of THE GARDEN know.—T. SMITH.

**National Chrysanthemum Society.**—The general committee of this society held a meeting at Anderson's Hotel on Monday last, Mr. R. Ballantine in the chair. Most of the business done was in view of the annual meeting of the members on Monday next, and occupied the attention of the members until an unusually late hour. The draft schedule for 1895 was received and passed except the classes for special prizes. The draft report for the past year and balance sheet were also presented, the latter showing that income had been received to the amount of £895 19s. 6d. Mr. Briscoe Ironside drew attention to the proposed alteration in the rules, which conferred upon the vice-presidents the privilege of being *ex officio* members of the floral committee, a body specially chosen for a particular work, and he thought it was to be feared that at some future time difficulty might arise because vice-presidents were not in every case Chrysanthemum experts. There was a good deal of discussion on this subject, and

ultimately the recommendation was withdrawn. The Windsor Horticultural Society applied for admission in affiliation, and a few new members were elected.

**The Jew's Mallow** (*Kerria japonica*).—Amid the prevailing wintry desolateness of the garden during the last week I was forcibly attracted by the soft green tint of the long rods or slender stems of *Kerria japonica*. A good-sized clump of this (some of the rods of which are over 10 feet high) grows close to a high Hawthorn hedge here, and with the ground covered a foot deep or more with snow and little else to strike the eye except the drab-coloured Gooseberry bushes and the darker brown of the Hawthorn hedge, this cheerful green clump of *Kerria* stems came out in very prominent relief with a most enlivening effect. Permit me to recommend it very strongly as an excellent subject for positions in which small conifers are often planted near dwelling-houses for a cheering winter view from the drawing-room windows. The pleasing soft green tint of the *Kerria* stems (in a good-sized clump) is infinitely more agreeable to the eye at that season than the sombre green of the foliage of conifers.—W. M.

**A fine new Violet.**—The San Francisco *Examiner* describes the new Violet named California the result of a chance experiment in cross-fertilisation of Professor Emery E. Smith as one of the botanical achievements of the century. Mr. Joseph Carbone, as the cultivator of the new flower, must share the honours with its raiser. The new Violet is described as follows by the *Examiner*: "The Violet has never before attained such beauty as it now possesses in its latest and most perfect development. The purity of colour, the delicacy of fragrance, the grace of form, and the unusual size of the California place it easily in the lead of all other flowers of its species, and with many it will rank as the most beautiful of all flowers." Professor E. E. Smith, in speaking of the flower, says, "It has been in the course of propagation three years, and has now attained its most perfect form, colour, fragrance, and size. It is a vigorous plant, absolutely free from disease of any kind, and so unlike many other Violets. Its flowers are of immense size, sufficiently large to more than cover a silver dollar. Its colour is a clear violet purple and does not fade. The fragrance is intense, and the stems vary in length from 10 inches to 14 inches"—W. E. GEMBLETON.

**A note on Pears.**—I have been reading with great interest the remarks by your correspondents on Pears, more especially as I am unfortunate enough to have between thirty and forty varieties here, many of which I do not even know the names of. I took charge of these gardens in the autumn of 1893, so have not had an opportunity of becoming acquainted with the good or bad qualities of this large collection, the season of 1894 being with us very unfavourable to them, plenty of fruit, but small and for the most part flavourless. The one exception as to size was Winter Nelis growing on a south wall. The fruit was above the average. Josephine de Malines, also on a south wall, bore a fair crop of fruit rather under the average size, and, strangely enough, about one half ripened well about the beginning of December and the other half is still in the fruit room, now ripening, but without a particle of flavour. A favourite Pear here for dessert is one called the Glastonbury Pear. The tree is trained over an arched trellis, and in 1893 bore a heavy crop of very fine fruit which ripened in October, the shape and colour resembling the variety Benedictine. I should have sent you a sample last year, but, like many others, the fruit was so small and spotted that they would not be recognisable. I should be obliged if any of your readers could tell me something more about it, and if it has another name.—T. CARTER, *Butleigh Court Gardens, Glastonbury.*

**The weather in West Herts.**—Although the weather during the past week has been a de-

cid improvement on that of the previous one, and there was a cold thaw on several occasions during the daytime, the frost which set in on the 22nd of January still holds, having now (Wednesday) lasted exactly thirty days. During this period the thermometer exposed on the snow has on no night indicated less than 11° of frost, and on five successive nights registered more than 30° of frost. On level ground the Grass has been continuously covered with snow from 1½ inches to 3½ inches deep for the last twenty-four days. The frost descended into the ground on the 18th to its lowest point—to the depth of 20 inches. Since then the thermometer at 2 feet deep has risen four-tenths of a degree, and that at 1 foot deep nine-tenths of a degree. There has been no measurable fall of either rain or snow for eighteen days. For over three weeks the wind has been almost constantly in the north-east—that is to say, during that time it has only blown from any other points than those between N and E.S.E. for altogether fifty hours. The 16th and 19th were very bright days for February, the record of sunshine amounting respectively to 8 and 7¼ hours.—E. M., *Berkhamsted.*

## MANURE FOR GRASS FIELDS.

WILL any correspondent inform me the best and most economical manure for the above? The soil is good loam, with deep gravel subsoil in south of England.—HAYLING.

\*\* Much depends whether you have manures at command or can obtain them readily, as the question of cost is a considerable item. The land being good loam, there are great advantages, and it is easier to select suitable manures. If animal manures can be obtained readily I would give them the first place. Horse manure is most valuable for a loamy soil, and if cow manure can be mixed with it, I do not know of any better material, as the subsoil being gravel, the manure is more holding and not so readily washed down when spread on the surface. But cow manure to be in condition must have fermented, and is excellent when mixed with other manures or soils. If mixed in such a manner that the ammonia is retained, few manures are more valuable for your purpose. By mixing, I mean taking each manure as gathered in small quantities and placing in small heaps, frequently turning, so that the heat is not too violent or the manure wasted by too rapid evaporation. This manure not only feeds the plants, but adds to the soil when placed on the surface, giving the surface roots greater strength; whereas artificial fertilisers cause a quicker root action, but not so lasting. Hence the value of animal manures. My next point is, can you obtain such manures in quantity and at a low price? If so, I advise doing so in preference to others, or if only a proportion can be obtained, dress a part of your land one year with the manure and give a light dressing of a fertiliser next. Some few years ago the writer took over 300 acres of Grass land that had been impoverished for years. Animal manures were too costly, and attention was given to night soil which could be had for carting. This was got in quantity and mixed with gaslime, placed in large heaps, and spread liberally early in the year. The cost was not much in comparison to other manures, and I never saw finer results. Perhaps you may be in a position to try this, but of course it cannot be used when fresh. I believe, however, that night soil mixed with road scrapings, man or soil is better than gaslime, as the lime destroys a large amount of the ammonia, which should be retained. My reason for using it was, having a heavy clay land to deal with it was required; in your case it is not. As regards artificial foods, they have not all the same value and require to be procured from a good source; then they are valuable for plants. Probably you will be unable to procure sufficient animal manure this season and must have other aids. The effects produced on Grass by nitrates is evident after such land has been neglected for years, and the outlay will be well repaid.—W. S. M.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## TREES AND SHRUBS.

## THE SCARLET-FRUITED THORN.

(CRATEGUS COCCINEA.)

WHERE the ornamental qualities of the specimen are the planter's principal consideration, this North American Thorn certainly deserves more than a passing notice, for both flower, fruit, and decaying leaves form a prominent feature of the tree at their respective seasons. The Scarlet-fruited Thorn is a native of a considerable tract of country in North America, and though known here for the last two centuries, its merits are not sufficiently recognised. It is a free, vigorous-growing tree, reaching a height of 20 feet or thereabouts, and is amply furnished with large, bright green, shining foliage. About the end of May the clusters of large white blossoms are borne in great profusion, while the berries which succeed them are, when ripe, of a bright coral-red colour, and in this state are remarkably conspicuous. In autumn, before the leaves drop, they become richly suffused with yellow, and here and there occasionally a flush of scarlet. The spines of this Thorn are long and formidable, but in most cases are but sparingly produced. As a medium growing tree for an isolated position on the lawn, the Scarlet-fruited Thorn is well suited; its ornamental qualities are then brought prominently forward. From the frequency with which it occurs in its native country, and the readiness with which it can be raised from seed, it is obvious there must be some well-marked varieties; still none of them are superior to the ordinary form, and some not equal to it.

Besides this, several other North American Thorns are very ornamental, prominent amongst them being the Washington Thorn (*Crategus cordata*), especially noticeable on account of its late-flowering habit, in which respect it is even more tardy than the European *Crategus tauacetifolia*, which is usually regarded as one of the very last, but I have seen the American species in full bloom when the European one was over. *C. cordata* forms a small tree, rather compact and regular in outline, with dark green shining leaves and large clusters of white blossoms. The berries are deep red, but no larger than those of the common Hawthorn, and are seldom borne in any great profusion. Thorns of the Cockspear class, represented by the typical species (*C. Crus-galli*) and several varieties, are all handsome, while among them are to be found some well-marked forms. In the typical Cockspear Thorn the leaves are bluntly ovate, of a bright shining green, and the whole aspect of the tree low and spreading. A fine bold variety is *arbutifolia*, in which the leaves are larger and the whole plant more vigorous than the type; while quite a curiosity is furnished by *linearifolia*, or *salicifolia*, as it is sometimes called, the leaves of which are narrow, while the branches extend in a horizontal manner, so that if grafted at a height of 4 feet or 5 feet from the ground the plant forms a flattish head, which renders it very distinct. A near ally of the Cockspears is *C. macrantha*, whose most prominent feature is the large curved spines, which in size surpass those of all

the others and present a most formidable appearance. The greenish yellow fruits of *C. flava* stamp it as a distinct North American Thorn, but it is certainly less ornamental than any that precede it, while the same remarks apply to *C. spatulata*, a low, but neat-growing kind with peculiarly shaped leaves, which are retained till late in the season, so that it is often quite sub-evergreen in character. The flowers are not particularly conspicuous, while the sealing-wax-like berries, though bright, are too small to be very showy. From a fruiting point of view, one of the most distinct of North American Thorns is *Crategus Douglasi*, which attains the dimensions of a small tree. It belongs to the early flowering section, and though pretty when in bloom, its most interesting stage is when laden with haws, which are freely produced. The berries are of a deep, almost blackish purple, and larger than those of the European *C. nigra*, the berries of which more nearly approach a black hue than do those of the American species. All the Thorns herein mentioned are perfectly hardy, and in no way particular as to soil or situation. T.

**Golden Scotch Fir.**—This is at its best during the dull days of winter, and on this account is more noticed than it would be later on. It is a compact, bushy growing form, whose foliage towards the end of autumn becomes of a deep golden tint, which is retained throughout this winter, till on the return of spring the specimen resumes its normal green hue, and remains in that state till autumn again sets in. From this peculiarity it is very desirable, as some of the golden *Retinosporas* become at times bronzed during the winter, and the tint of this Fir is very bright and cheerful. It is by no means the only well-marked variety of Scotch Fir, there being among others a silver variety (*argentea*), in which the leaves are of a silvery grey tint when first expanded, but lose their brightness later on. It is more tree-like in growth than the golden form. Among the varieties remarkable for differences of habit may be especially mentioned the Highland Pine (*horizontalis*) and a weeping form (*pendula*), whose branches droop in some instances a good deal. A direct contrast to this last is furnished by the variety *fastigiata*, almost as upright as a Lombardy Poplar, and a specimen of which among other Firs stands out very conspicuously by reason of its marked divergence in habit. The dwarf form *globosa*, that rarely exceeds a yard in height, suggests some of the miniature varieties of the Spruce, which are so plentiful.—T.

**Ruscus racemosus.**—This, known also as the Alexandrian Laurel, is decidedly the most ornamental of the hardy members of the family, and is in many respects a very desirable little shrub. It is altogether a more graceful subject than the Butcher's Broom (*Ruscus aculeatus*), and its slender shoots reach a height of 3 feet to 4 feet, a well-established clump then suggesting an affinity to some of the hardy Bamboos. The leaves, or rather cladodes, are about a couple of inches long and of a deep shining green. During the spring the flowers make their appearance in little clusters at the points of the shoots. They are small and greenish white, and are consequently not particularly showy. Apart from its desirable features as a graceful little evergreen shrub this *Ruscus* is very valuable in a cut state, as the slender shoots clothed with their deep green foliage are most effective when arranged in a vase, particularly if lit up by a few flowers. In this way the foliage remains fresh for a very long time; indeed, it is one of the most durable evergreens that we possess for such a purpose. It succeeds best in a partially shaded spot, and under such conditions will thrive better than many other subjects on a chalky soil. The common Butcher's Broom (*R. aculeatus*) will succeed under the drip of trees better than most shrubs. It is entirely evergreen in character, and if the berries are pro-

duced in quantity, they are when ripe very ornamental. At the same time the fruits are in many instances sparingly borne. The curious *R. hypoglossus*, in which each leaf produces a smaller one from its midrib, is both curious and ornamental. A strong-growing kind is *R. androgynus*, a native of the Canary Islands. This needs the protection of a greenhouse, and as a vigorous climber for large structures is very effective. In the temperate house at Kew and in the Crystal Palace it covers a considerable space. While the whole of the above were at one time included in the genus *Ruscus*, and are now-a-days always spoken of as such, this last is by botanists grouped by itself under the name of *Semele androgyna*, and the Alexandrian Laurel is *Danae racemosa*.—T.

## SHORT NOTES.—TREES AND SHRUBS.

**Hedera maderiensis variegata.**—"E. J." (p. 74) does well to call attention to this silver-edged Ivy as a subject for house decoration at this season of the year. Nothing could be more effective when arranged with dark-foliaged plants and Ferns, the broad snow-like band standing out in bold contrast to its surroundings.—E. MOLYNEUX.

**The Tulip Tree in the north.**—There is a fully matured specimen of *Liriodendron tulipifera* standing in the grounds belonging to the Right Hon. Lord Houghton, Frystone Park, Ferrybridge. I have seen it bearing flowers equal to any tree of the same species growing in the southern counties. It stands in a dry and sheltered position, and is about 30 feet in height, with a good spread of branches. When I saw it last it was showing signs of decay on the upper extremities, owing, perhaps, to the age of the tree and the climate.—A. R. S.

## COLOUR IN FLORISTS' FLOWERS.

AN acquaintance with our old florists' flowers runs back through more than forty years of my life, and I may, therefore, confess to a long and early love for these plants of special types and selected beauties. Without them the garden would not be, horticulturally, home to me. Like nearly all the brotherhood of florists, I have grown other things as well, and enjoyed them all, but no plants are so associated with the garden memories of a lifetime or recall them so tenderly and so unchangeably as the old florists' flowers.

A few writers on matters floricultural, without anything like love or practical knowledge of these plants, seem to enjoy having a fling at florists for the singleness and intensity of their aim, but probably they amuse us as much as we amuse them. They confuse issues. I am not sure that my friend Mr. Douglas is "bright, rich, and deep" in the colouring of his views on the colours of florists' flowers in his paper of Feb. 9. I do not know the two Carnations which are so artistic, yet rejected of strict florists, but in a rose flake variety, a very pale tint, probably fading with age, and possibly associated, as weak colours often are, with petals of thin substance, would not stand so high with an expert judge as a clear substantial shade of rose—a colour capable of much good variety. The flower might be weak in points of form that would submerge a prettiness of colour. Well formed does not consist in a mere multiplicity of petals, but in the breadth, and substance, and smoothness of each. Many of the southern flowers have been too full and confused, and their strength of a type not calm and powerful, but fussy and indistinct. The white ground Carnation with beautiful rose and purple markings should, by that, be a pink and purple bizarre. Perhaps the third colour—which makes the bizarre, and is here the purple—was insufficiently expressed. In a well-marked flower every petal contains each colour

characteristic of its class. Curiously, although that third colour in the bizarre Carnation is the darkest—and thus presumably the strongest—it is just the one which is apt to wear out gradually with the age of a variety, or to disappear suddenly, leaving the flower a sport into the two-coloured flake classes. Hence a young variety in the bizarre section should possess the third colour in abundant strength to allow for very possible diminution in later life. Third colours are stripes of black, crimson, purple and deep scarlet, and are most highly prized and effective features. There is little fear of the bizarre colour being overdone.

But colours are only half the flowers' wealth and show their beauties but partially on a bad form, by which in the Carnation is meant narrow, strappy, twisted, saw-edged petals. It is too wide an assertion to say that in the florists' Carnation we insist that "the colours, whatever they are, should be of a dark, and not a pale tint"; for then where were our rose flakes and pink bizarres? where the light purple-red and rose-edged Picotees? These are of tints comparatively light, yet still may be of shades bright, deep (not in the sense of dark) and rich. But they are not to be washy or evanescent. There may be something artistic and harmonious in such pallor, but, as the boy said of his harmonious blue milk, "This is indeed weakness!" We require that a florists' flower shall die well.

In Auriculas, my friend deprecates the casting out of edged flowers with violet or plum body colours in favour of those with a black ground. But I do not recollect "a splendid truss of perfectly formed flowers" with a violet or plum body colour rejected because of that. There is Col. Champeys, a kind of puce ground grey edge, and Chapman's Maria, an almost white edge with deep violet body, and Moore's Violet, an old green edge with violet ground, and Countess of Dunmore, a white edge with chocolate ground; but in these and others that I could name the edge was so insufficient or, as the flower grew, was so broken into by the ground colour, that the harmony of proportion was broken up. Along with this went the further fault of inconstancy of these ground colours. Black has been alike the favourite body colour of our best edged Auriculas, and the colour that lives densest and truest till the flower dies. No one but two northerners may remember it, but the best Auricula, with a persistent blue ground colour and snowy white edge in fine proportions, was a seedling of Mr. Simonite's at the London show now many years ago. It never lived to see another—it died of going to London. He and I have for years tried for edged Auriculas with blue, violet, or crimson body colours, but with very partial success—nothing yet that will equal in other properties the black ground edges. So also with the gold-laced Polyanthus of the florist types. If any red grounds were equal in their respective properties to the black ground flowers, they would not be rejected. Lord Lincoln in black, and Kingfisher in red ground varieties were an ideal pair, of most lovely and forcible contrast, but both are lost now. It is a most important point that the gold of the lacing should be as rich as that of the eye and of the same tone of yellow. The lacing is but a golden thread, and a difference in colour on the side of weakness looks threadbare and poor.

I would also embolden the diffidence of my friend on the Tulip, whereof he remarks that the florists' Tulip may have a rich dark-pencilled feathering, but the beam, as it is termed, of a light colour. Or it may have a rich red or dark crimson on a deep yellow ground, and because

of these two colours it is again rejected. "It is a tricolor; it is of no use," says the florist. But verily he does not say that. The florist's inadmissible tricolor is not a flower that has two colours in markings, but one that has a dirty mixture of two colours in its ground of white or yellow. What we mean by a tricolor and reject is a Tulip in which the ground colour, that should be decisively a pure white or yellow, is instead a washy or streaky compound of both. A flamed Tulip is not condemned because the beam of the flame is centrally more glowing, with an intenser colour as if by the fervency of a higher heat. Nearly every one of our best flamed Tulips has this beauty and emphasis of two colours in the beam of the flame. Sir J. Paxton, a model flower, has it in force; Ajax, a lemon ground with black feather and flame, has a crimson beam in the centre of the flame; while in Wm. Lee, the feather and flame are black throughout. Storer's Dr. Hoteheon (I think our best flamed bizarre) has vivid flashes of intense crimson among the dark flame tongues and beam. Scarlet bizarre Tulips, like Dr. Hardy and Orion, have beams flamed with deeper red. So in the class of rose Tulips with scarlet markings on a pure white ground, the flamed flowers are beamed with a lighter or darker shade of red, as in the deep crimson beam of old Aglaia or the pinker flash than the scarlet in Mabel. The same marked feature occurs in the different class colour of the other white ground flowers, the byblemens, with black or violet markings. The only point on which the beam of the flamed Tulip would be accounted weak is where the central colour in it is only a relic or infusion of the old original mother or breeder colour, *i.e.*, the maiden colour of the variety while it was yet in its seedling, self-coloured state of existence. That infancy of colour is inexplicably laid aside when the flower breaks into its completed colouring, and we do not like to see it again if it were very curious, nondescript, and weak, not to say artistic, as in flowers like Masterpiece, which as a feathered flower is jet black on a deep gold ground, but in its self-coloured or breeder form is exactly the harmonious blend of brimstone and treacle.

All the rose class are lovely as breeders, and many of the byblemens too, but some seedling forms of the bizarre class are very old. As to the allowance of stained stamens or filaments (not anthers, for these are always black or yellowish, according to the colour of the pollen upon them), we adhere to purity, and not smudginess of these. They harmonise better so with the pure white or yellow cup than if imbued with a dull and dirty inky tinge.

It may not be easy to explain why a smut upon the nose is so ridiculous, but so it is. Yet are not two colours richer than one? Still, we have a narrow-minded, arbitrary, and florist-like preference for that stamen of the countenance to be unstained. Put it thus, if you will, about our florists' Tulip. The flower is fairer, more lovable, more harmonious with filaments as pure as the silver or golden cup, and no enactment that would allow stained stamens or impure base would ever be recognised or sanctioned by florists who know or grow the Tulip.—F. D. HORNER, *Burton-in-Lonsdale*.

I am glad Mr. Martin Rowan has alluded to the Carnations referred to by me in the paper published in *THE GARDEN*. I am sure there is not much difference of opinion between Mr. Rowan and myself. I had not in my mind when I wrote such growers of florists' flowers as he is. In regard to my Carnation Harmony, I must insist on its being placed in

the class of pink and purple bizarres. The colours are a true pale pink and purple on a white ground, and when Mr. Rowan says "it could only be by courtesy a pink and purple bizarre" I do not follow him. I assert it was not admitted by the florists because of the pale pink stripes and flakes. There can be no doubt about the purple colour; it is not a fancy in any sense of the word. Our leading flower artist, Mr. Moon, and other tasteful persons found certain beauties in it when it was grown in the open borders of the garden at Gravetye Manor. The pale rose colour was there considered a merit which by a leading northern florist was a disqualification. Mr. Rowan will see that I merely wished to point out the difference between a florist who examines a flower with certain preconceived notions as to colour, and an artist, or any other tasteful person, who has been educated to a knowledge of colour effects. The same remarks hold good as regards the rose flake Carnation, and in this connection what does Mr. Rowan mean when he says that Dorothy was as a rose flake but a half-developed flower? How half developed? I had plants of it and grew it under my own eye, and can assert that it was a large, handsome, well-developed flower as regards petal; indeed, one of the largest, the colour a soft pale rose. This pale colour was the only fault any grower found with it. I appreciate the pink and purple bizarre and the rose flake as much as Mr. Rowan does. What I complain of is drawing the line at any particular shade of colour.

Mr. Rowan tells us "that so far from florists despising or rejecting the beauty which belongs to Carnations of other types, classes for these are provided at the exhibitions of all our societies." True, quite true, this. But Mr. Rowan does not tell us who first provided these classes for the outcasts. Not Mr. Rowan, for I fancy they were provided before his time. Not the florists to whom I have already alluded. The florists opposed them, and would have none of them at first. It was the raiser of Harmony who first suggested these classes, and they were put into the first schedules of the National Carnation and Picotee Society (Southern Section). The old florists, like other people, have had to stand aside before the effects of a more liberal interpretation of what is form and colour. In the same manner I suggested classes for fancy Auriculas, and these classes have been in the schedules of the Auricula Society ever since we were able to show collections of them. The classes are seldom well filled, because florists will not grow them; but here again we have the evidence of one of our leading artists who discerns beauty and infinite variety in the fancy Auriculas. Most of those in cultivation have been raised from seed by me, and I have carefully saved and cultivated them for many years. I do not much care whether they come into the florist's definition of a florist's flower. I can grow these and admire them at the same time that I value at their true worth the green, grey, white, and self-edged varieties. This matter of colour and form in florists' flowers gives rise to contention at certain intervals when the subject is taken up in the gardening papers. I believe in a standard of excellence to which florists should work up their seedlings. In all the seedlings I raise I have a certain standard in my mind's eye, and have not been unsuccessful even from a florist's point of view. I took up the yellow ground Picotee some years ago, and as evidence that the florists appreciate my work, they have returned in an election of varieties nearly all my seedlings, and I try to get every shade of colour I possibly can.—J. DOUGLAS.

## ORCHIDS.

## VANDAS.

WHERE there is plenty of room for their full development the larger growing members of this fine Old World genus are among the most beautiful Orchids in cultivation, and there is hardly a species in the genus that is really difficult to grow provided a suitable temperature is maintained. To grow such as *V. cœrulea* and *V. teres* under the same conditions is to court ultimate defeat, as the heat required by the latter is far too much for *V. cœrulea*. This kind will thrive well if given a place in a temperature slightly higher than *Odontoglossums* require, and being rather a restless species, must not be dried at any season. It must also have an abundant supply of fresh air and sun-

growth by exposure to sun and air in autumn, they get along fairly well in the same house. The smaller-growing kinds like a position near the roof, and may be reared in wooden baskets or small pans, according to convenience. Sphagnum Moss will form the basis of the compost for all, being about the best material for their large fleshy roots to thrive in. Charcoal or potsherds must be used with it, broken to various sizes according to the size of the pot or basket. None of the species like disturbance at the root; therefore when repotting give good drainage, and use nothing that can become sour or cause waterlogging of the compost. Fresh layers of Moss may, however, with advantage be added yearly, at the same time removing some of the old and any decaying roots that can easily be got at, and covering as many as possible of the air-roots with the new Moss. The chief insect enemy to Vandas is a small white

account must it be left lying about during the daytime or entrusted to irresponsible persons. It is impossible in this note to deal fully with all the species, but those mentioned below will make a very interesting collection.

*V. AMESIANA* has not been in cultivation long, being introduced by the Messrs. Low and Co. from India in 1887. It is of the dwarf-growing section, and has flowers varying in their tints of rose and pink. A pure white variety, *alba*, has also been described. It may be grown in a comparatively cool house, but the temperature must not fall much below 50° at any time. It blossoms from May to July, and lasts a long time in perfection.

*V. BATEMANNI* frequently grows to a height of 4 feet or 5 feet, and the leaves, which are very thick and leathery, grow from 18 inches to 24 inches in length. The flowers are produced on long, erect spikes, and are 2 inches across, golden-yellow, freely spotted with bright crimson. This kind must have plenty of heat while growing, but 50° to 55° is quite high enough for it during winter, or, indeed, for any in the genus. It is a summer and autumn-blooming species, and was introduced from the Moluccas about 1844.

*V. BENSONI* is not a showy kind, but very well worth growing. It is a native of Burmah, and was introduced in 1866; like its ally, *V. Roxburghi*, it requires a strong moist heat while growing. The flowers are about 2 inches across, and occur on racemes about a foot in length; the sepals and petals are yellowish, spotted with red, the lip rosy-purple, margined with white.

*V. CŒRULEA* (see illustration) is a gem of its kind, and probably the best instance of a blue-flowering Orchid. The sepals and petals overlap, making a full and beautiful flower, the best varieties being quite a decided blue when fully developed. This grows from 1 foot to 2 feet in height, and flowers during the autumn months. It is now fairly common, although for a long time after its introduction it was very rare and valuable. It is a native of the Khasia Mountains, whence it was introduced in 1869.

*V. CŒRULESCENS* is a spring-flowering Orchid of great beauty, growing about 18 inches high and producing erect spikes of pale blue flowers, the lip deeper in colour than the segments. This thrives in the Cattleya house suspended in baskets, and has been in cultivation since 1869. A variety of this known as *Boxalli* was introduced some time after, and is much lighter in colour than the type, the sepals being nearly white and the lip deep violet.

*V. HOOKERIANA* requires a strong moist heat and plenty of sunlight while growing. The flowers are usually produced in pairs upon the spikes, each being about 2 inches across. These are creamy-white, more or less spotted with purple. It was first introduced in a living state by Messrs. Low and Co. in 1873, but did not flower until some ten years afterwards.

*V. KIMBALLIANA* is a delightful species which first flowered with the Messrs. Low in 1889; it is not so strong in growth as *V. Amesiana*, which it somewhat resembles, the leaves being more cylindrical. It does well under cool treatment, and should be kept well up to the light. The flowers have a white ground colour with a purplish-crimson lip.

*V. SANDERIANA* is a grand species, bearing large racemes of flowers, each upwards of 4½ inches across, mostly of a brilliant rosy lilac shade. It should be grown in the warmest house, and likes abundance of atmospheric moisture. It is a native of the Philippine Islands, and was introduced in 1881.

*V. SUAVIS* and *V. TRICOLOR* may be bracketed as far as treatment, habit, and shape of flowers are concerned. They are in fact identical in everything except in the ground colour, that of *V. suavis* being white, *V. tricolor* yellow, and as there are intermediate forms between the two kinds, this seems hardly enough to warrant their being entitled to specific rank. The flowers are all more or less spotted, usually with crimson, and deliciously fragrant. They were both intro-

*Vanda cœrulea* in flower. Engraved for THE GARDEN from a photograph sent by Mr. E. H. Woodall, St. Nicholas House, Scarborough.

light, or it will not flower freely. If an intermediate house is not at command, it may, however, be very well grown in the cool end of the Cattleya house, and should be placed near one of the ventilators. The large-growing species, such as *V. suavis*, *V. gigantea* and *V. Batemanni*, are best grown in large pots on the central stages in large roomy houses. Here the atmospheric conditions are not so likely to fluctuate as in narrow, low structures, and the plants, being arranged further from the glass, need less shading than would otherwise be required. They must be treated liberally to induce them to grow as quickly as may be into large specimens, as small pieces never flower satisfactorily, nor is their full beauty seen until they attain a large size. Plenty of heat may be given in the summer to the last-named species, *V. suavis* and its ally, *V. tricolor*, requiring less, although if pains are taken to consolidate the

scale, which clings most tenaciously to the leaves. At the first appearance of this pest the plants should be looked through and carefully sponged, going over them a second time about a fortnight afterwards. This is more important than at first sight appears, for if once these insects get a hold on the plants the spongings will have to be very frequent, and this operation is in some hands very injurious to the foliage, sufficient care not usually being taken to avoid puncture. Cockroaches, too, are often troublesome, eating through the roots and flower-spikes, and doing an immense amount of mischief. The best way to clear a house of these is to lay poison about at night near the plants they infest, making this by using a paste of flour, lard and sugar, adding thereto a small quantity of white or pure arsenic. It is hardly necessary to say that great care is necessary in handling this dangerous mixture, and on no

duced from Java in 1847, and are noble and stately Orchids well meriting a place in the choicest collections.

V. TERRES is a remarkable species of straggling climbing habit if left alone. The flowers are very beautiful, and when the plants are properly treated they are freely produced. It was introduced from Burmah in 1828, and requires a strong moist heat while growing. The racemes occur near the apex of the growth and bear from two to five flowers. The sepals and petals are bright rose colour streaked with golden yellow. Many cultivators are in the habit of cutting the plants of this species over annually, rooting the tops in strong heat, so as to obtain dwarfer, more compact plants which flower freely during the summer months. H. R.

**Orchids from Leeds.**—I should deem it a great favour if you would, through the columns of THE GARDEN, say whether any of the flowers enclosed are special varieties, or only the ordinary run of the type to which they belong. The Cattleyas were all imported last season, the C. Schilleriana very late, whilst the flowers of C. Trianae are cut from seven different plants, No. 1 having been out a fortnight. The two varieties of C. amethystoglossa are both carrying good spikes for imported plants, one ten, the other fifteen. The Cypripediums are C. euryandrum, which, as you will notice, was twin-flowered, and C. Lathamianum, carrying seven flowers. The flowers of *Odontoglossum nebulosum* have been out some time. — T. TYSON, *Roundhay Mount Gardens, Roundhay, Leeds.*

\*\* Very good forms all of them, but not valuable. Now-a-days varieties must be of unusual excellence to be better than existing types.—Ed.

**Phalænopsis leucorrhoda** (*Grower*).—This plant is a supposed natural hybrid between the lovely variegated-leaved species P. Schilleriana and P. Aphrodite, and will produce its blossoms at different seasons of the year according to the strength of the plant. It is a rare and expensive kind, and produces a magnificent flower intermediate between the two supposed parents. This genus requires to be kept in an atmosphere constantly charged with moisture, and if your plant is in good health I would not advise re-basking. If this be necessary, care must be taken not to break or injure the roots which cling to the old wood. It does not require any peat, good living Sphagnum Moss being all that is needed, and this should be kept in a living condition.—W. H. G.

**Lycaste Skinneri alba.**—I have recently noticed one or two fine specimens of this superb Lycaste, which is certainly one of the most beautiful of all white-flowered Orchids. It also has the same advantage as the typical plant, of lasting an exceedingly long time either upon the plant or in a cut state, providing the blooms are not sprinkled with water. This pure white form is a very chaste and lovely flower, and appears to become more plentiful every year, although even at the present time the true variety is by no means common, still commanding a high price in the market.—W. H. G.

**Odontoglossum blandum.**—A very lovely species is this, coming from the United States of Colombia. It grows upon the trunks of trees which are situated in moist localities at about 6000 feet altitude, and it is stated by different collectors to be in bloom nearly the whole year. Under cultivation, however, we find that it mostly produces its blooms during the spring months. These are borne on a nodding raceme and are thickly set. They are creamy white, spotted and blotched with reddish-purple.—W. H. G.

**Ada aurantiaca.**—This is a fine Orchid for the cool house, its bright orange-red-coloured flowers being very useful for making a bright display during the dull winter and early spring months. A spike of this recently came from "S. M.," who states that he has had it in beauty for several weeks, and how charming it looks when intermixed with *Odontoglossums*. This

plant should find a place in every collection on account of its bright colour and freedom of flowering. It is, moreover, of easy culture, requiring to be grown in a pot with good drainage and fibrous peat and Sphagnum Moss, and given exactly the same treatment as the well-known *Odontoglossum crispum*. It is a native of New Grenada, where it grows at considerable elevation, and produces arching spikes of orange-vermilion-coloured blossoms.—G.

**Oncidium concolor.**—It is not too soon for this very bright and useful little species to flower, and if not kept too warm during the winter months, will probably bloom about the month of May or June. G. Smedley inquires if it is a plant worth growing in a small collection where insignificant little species are not required. I know of no better subject than this—in fact it is essentially an Orchid suitable for all amateurs, requiring but little heat and only a small amount of room to grow, and producing freely fine spikes of very showy flowers. O. concolor is a compact-growing little plant, and has been known in this country for more than fifty years. The pseudo-bulbs are furnished with a pair of bright green leaves, and do not exceed both together more than a foot in height. The spike which appears from the base at the bulb is very densely set with blooms and drooping. Small shallow pans are best adapted for the culture of the plant. These should be suspended near the glass at the coolest end of the Cattleya house in the winter, but a little more warmth may be given if required to flower earlier in the season. Fibrous peat and chopped Sphagnum Moss is the best compost; a few nodules of charcoal may also be added, and care must be taken that the drainage is in good order. After the growths are completed this species should be kept rather dry, and during the summer the cool *Odontoglossum* house will suit it admirably. The flowers, which are large, are of a soft delicate yellow in some, whilst others are of a much brighter shade, and the large flat lip is very conspicuous. On well-grown examples a spike will often carry over a dozen of these bright blooms.—W.

#### VENTILATING ORCHID HOUSES.

At no season of the year is more care necessary with the ventilation than the present, when bright bursts of sunshine alternating with cold drying winds and frosts necessitate those in charge being always on the alert. Fruit growers are only too well aware of the mischief caused to tender Vine or Peach shoots by neglect for only a few minutes at a critical time, and although Orchids do not show the results of bad management in this respect so soon, yet sudden changes in the atmosphere can have no other than a prejudicial effect upon the plants. As I write, it is intensely cold outside, and no doubt the glass will fall to about 15° during the night, while at midday it was quite balmy and spring-like. The pipes have to be well heated at night to keep the temperature in the warm houses from falling unduly, and if these are kept close in the morning the heat goes up with a rush as the sun rises, the foliage feeling quite hot to the touch in a very short time. This state of things is quite wrong and very trying to the plants. If a little air is given on top soon after the sun reaches the house, the temperature rises more steadily, the night moisture is gradually and in a natural manner dissipated, and a far more congenial atmosphere produced. This chink of air is usually sufficient at this time of year without opening the side ventilators, and even this must be closed soon after midday. If the sun is bright the houses must be damped rather freely, but not enough to cause a steamy atmosphere. Except when very cold winds are blowing, the lower ventilators opposite the hot-water pipes in the Cattleya house should be opened a little during the day, but closed on cold nights.

This keeps up a constant supply of fresh air to the plants and does not appreciably lower the temperature. These ventilators ought always to be covered with perforated zinc, which prevents a rush of cold air to the plants by breaking up the current, so to speak. In the cool houses these ventilators can be kept partly open night and day, and enough air given at the top of the house to keep the temperature up to about 60° in the morning, rising to 65° at closing time. When the weather is dull and the wind cold, very little ventilation is required in any of the houses and the temperature should be kept about 5° lower than on bright days, too much fire heat causing a weakly growth, and tending more than anything else to the propagation of insects. Air, heat, and moisture must, to use a familiar expression, go hand in hand. Whenever a rise in the temperature makes free ventilation advisable, the atmosphere requires to be replenished with moisture in a like ratio. Too much heat or moisture and too little air are quite as bad as the opposite conditions, but a constantly changing and well-balanced temperature is one of the most important points in the culture of these beautiful plants. H. R.

**Odontoglossum Alexandræ flaveolum.**—I noticed this very distinct variety in flower upon a recent visit to the Victoria and Paradise Nurseries, the plant carrying a fine spike of many blooms. These were of good form and fine substance, being entirely without spots on the sepals and petals, which are of a primrose-yellow colour, the lip being flushed with creamy yellow and slightly spotted with chestnut. It is a very handsome and distinct form.—W. H. G.

**Lycaste lasioglossa.**—Although not one of the most showy Lycastes, this is a distinct and interesting species introduced about twenty years ago from Guatemala by Messrs. Veitch and Sons, and requires similar treatment to other members of this family. The pseudo-bulbs are about 5 inches in length, which, together with the lanceolate plicate leaves, give the plant a height of about 2 feet to 2½ feet. The blooms are large, of good substance, and are borne upon erect scapes 7 inches or 8 inches high. In the flower before me the sepals are spreading, all being about the same size and of a uniform dull chestnut-brown, tipped with green; the petals are concave, reflexed at the ends, and of a clear light yellow, and the lip, which is also yellow, has the front lobe densely covered with long whitish hairs, which give the plant a very singular appearance.—W. H. G.

**Odontoglossum Rossi albens.**—All the forms of *Odontoglossum Rossi* are beautiful, being of dwarf habit, very free-blooming, and easy to grow. They should be cultivated in quite a cool temperature and placed close to the glass, being kept nice and moist all the year through, when they will grow and flower profusely. The variety here referred to is one of the most distinct of this species, and may well be termed the "albino" of this type. It is by no means a common plant, but a very nice example is now in flower in the Victoria Nurseries, Upper Holloway. The plant resembles the typical form, but the flowers are pure white, with a few quite pale green spots at the base of the petals and a bright yellow crest on the lip. These individually are of good size and form a fine contrast to the darker forms.—W. H. G.

**Odontoglossum maculatum.**—This is one of our best known and most useful kinds. It produces its blooms at different periods of the year, although usually in the months of March and April. At the present time a fine form is in flower at Harrow Weald House, carrying some good spikes of large blooms, individually about 3 inches across and of good colour. O. maculatum is a plant that has been known in our gardens for many years and is a native of Mexico, where it grows at a high altitude upon the mountains; con-

sequently it enjoys cool treatment under cultivation, and succeeds best in a pot with good drainage, with a compost of fibrous peat and Sphagnum Moss. The plant greatly resembles *O. cordatum*, especially in habit and growth. The flowers are very showy, with brown sepals, barred with green at the base; the petals larger and wavy, light yellow, spotted with brown on the basal half, as is also the triangular-shaped lip.—W. H. G.

FLOWER GARDEN.

VERBASCUMS.

THE best Mullein grown in gardens is undoubtedly *V. phlomoides*, and although an old introduction, it is only within recent years that

*Verbascum olympicum.*

much notice has been taken of it and its great merits fully recognised. It is a true biennial, as easy to grow as the common Foxglove, and equally certain to flower. A plant so noble and beautiful in lasting bloom should have an important place in our gardens, and it is one of the good things that can be grown in quantity if a packet of seed be sown at the right time. From early summer till autumn is well advanced flowers come in succession upon the tall spikes, and a group or mass makes a picture of lasting interest and striking beauty. No soil or situation apparently comes amiss to it, but, wherever grown, it should be in a bold free way, not dotted about at regulation distances along the border. The Olympian Mullein—a much more recent introduction—has lately become rather popular, but it is never quite so good as the preceding kind, nor capable of producing such good effects. When in flower it is a remarkably showy species, and those who see it then are apt to form too high an estimate of its worth. It is called a biennial, but it cannot be depended upon to flower the second year, three and sometimes four years passing before the flower-spike appears. All this while, however, it is a plant of much beauty, having noble tufts of silvery, woolly leaves, which individually are often 3 feet long and 4 inches broad. In flower it attracts much notice by reason of the tallness and symmetrical branching of the spike, which sometimes attains 10 feet in height, and the multitude of flowers that are open at one time. They are much smaller than those of *V. phlom-*

*oides*, and though exceedingly great in number, the plant does not last in flower more than about three weeks. Further, to do it justice, it must have more care in choice of situation, and only grows to its full dimensions and greatest beauty in deep, warm, well-drained soils. A very handsome Mullein that merits more attention in gardens, especially as it is a true perennial, is *V. vernale* or Chaixi. In flower beauty it is identical with and similar to our native species *V. nigrum*, but has the additional advantage of great height, sending up its noble spikes 6 feet or more. A white-flowered form of *V. nigrum* should become popular when better known and more plentiful. *V. phoeniceum*, about which several notes have lately appeared, is also a pretty garden plant, often perennial, but in any case easy to grow from seed, whilst it embraces a variety of tints, except yellow, the predominating hue of Mullains generally. It is well to bear in mind that the flowers of this kind droop and wither in the sun; therefore in order to enjoy its beauty throughout the day it should be grouped at a spot where only the early morning or late evening sun reaches it. A. H.

LILIUM BROWNI AND ITS VARIETIES.

THE beautiful plate which appeared in THE GARDEN of February 9 will, I feel sure, be fully appreciated by all Lily lovers, and also the able article accompanying the same. But with all due deference to "W. W.," I would submit the following remarks on the varieties of *L. Browni*. Firstly, as to *Lilium Browni*. By this I mean the *L. Browni*, figured as *L. japonicum* in THE GARDEN, vol. xxix., 1886, page 350, which is the *L. Browni* of commerce, so largely grown and distributed in our gardens. This is undoubtedly the Lily introduced by and named after Mr. Brown, nurseryman, of Slough, about 1838 or 1839, but how he became possessed of the same, whether it was a seedling or imported plant, history does not tell us. Of one thing I am quite sure, it has not been imported from China or Japan for many years, if ever, and the stock in this country and on the Continent is kept up by propagation; so on this point and the following I must differ from "W. W." when he states that "*L. Browni* is not a popular Lily." I find it a good doer, succeeding admirably in a well-drained situation, much sought after by all Lily cultivators, and considered by many to be one of our finest hardy Lilies.

Now with all due respect to M. Franchet, "W. W.," and other authorities, I would suggest that the Lily described by M. Franchet as *L. Browni* in his very interesting paper (THE GARDEN, vol. xliii., 1893, page 41) to which "W. W." refers is *Lilium odorum* of Planchon or *japonicum* Colchesteri, introduced into this country in 1804 and figured in the *Botanical Magazine* in 1813, or, as it is now popularly called, the Japanese *Browni*, which is largely imported every year from China and Japan, and perhaps "W. W." refers to this species when he speaks of *L. Browni* as not a popular Lily, for this form does not succeed so well under cultivation in this country. *Lilium odorum* was in cultivation many years before *L. Browni* (Brown) was heard of; it is widely distributed over China and in many parts of Japan, it has a whitish coloured bulb, the foliage is shorter, broader, and of a lighter colour than that of *L. Browni*; the flowers when fully expanded are of a beautiful cream colour, externally splashed and streaked with rich chocolate-brown. The colouring greatly depends on the amount of sun

the plant receives. I have seen plants grown under glass which did not exhibit any signs of external coloration. M. Franchet describes *L. Browni* as "tinged with violet (red-brown) on the outside." This seems to refer more to *L. odorum* than *L. Browni*, which latter is wholly coloured externally with intense reddish brown. The *L. Browni* spoken of by Dr. Henry as growing near Ichang, if I may so suggest, is probably *L. odorum*. Last year we flowered here a very fine specimen, 4 feet high, from a batch of imported *L. Henryi*. *L. Browni* may be a true species, but surely *L. odorum* should be also classed as a distinct and true species, not as a variety of *L. Browni*. *L. odorum* is found wild in many parts of China and Japan, but, as before stated, I have never heard of nor seen a collected plant of *L. Browni* similar to the form grown in our English and Continental gardens.

*Lilium Browni chloraster* and *leucanthum* are two very fine Lilies indeed and very distinct, especially the latter. As to the true *L. japonicum* of Thunberg, I hope to have it in flower this year, or next at latest, the form described by M. Franchet as bearing cup-shaped white flowers. Whether this will turn out to be Thunberg's *L. japonicum* is a matter that must be left to the future to decide.

Colchester.

HYACINTHUS AMETHYSTINUS.

THIS lovely little Hyacinth, which comes from the south of Europe, is at present rather scarce in gardens, but it is a precious and very beautiful kind. It is quite hardy and a slender graceful thing compared with the large spiked Hyacinths with which everyone is familiar. It comes much later into bloom and its flowers appear very late in the spring. They last for a long time and possess a special distinctness by reason of their clear delicate amethyst-blue shade. The flower-spikes grow from 9 inches to 1 foot in height and bear many flowers, which, though tiny, have a pretty effect if the plant is grown in a little group or mass rather

*Hyacinthus amethystinus.*

closely. It is one of those choice things that merit a special position, such as a nook to itself at the base of a rock in the rock garden or at the foot of a wall safe from digging and disturbance. There is a white form, but the greatest

beauty belongs to the type itself in possessing a delightful shade of blue so different from that of other spring flowers  
A. H.

### FLOWER GARDEN NOTES.

**ANNUALS.**—For general flower garden purposes annuals may be roughly divided into two classes: those which, owing to their brief, though brilliant season, are only suitable for outlying parts of the garden where duration of flower, coupled with neat and tidy borders, are not essential features, and those which for a long sustained and effective display will vie with the best of the cutting-struck bedding plants. Again, there is a fairly clear dividing line between those which should be shown under cover, pricked off into frames or boxes, and then transplanted to summer quarters and others that do best if sown in the open where they are to remain throughout the season. This latter distinctive feature does not necessarily follow that mentioned in the preceding paragraph, because some of those sown in the open and that are the least trouble are also some of the most enduring. The comparatively recent introduction of some first-rate taller annuals has given a height not previously obtainable in the family, so that we now have them from the pegged *Phlox Drummondii*—that can be kept at a height of from 3 inches to 4 inches—to the small-flowered Sunflower and the varieties of *Cosmos bipinnatus*, that run up to 4 feet or 5 feet. The three above-named, together with *Nemesia strumosa*, a thoroughly good strain of early flowering Stock, of which Princess Alice may be cited as an example, and a strong and dwarf strain of *Petunias*, as respectively Giants of California and *nana compacta*, rank among the best of the annuals that should be sown under glass. The brown and yellow French Marigolds and the tricolor strain of annual *Chrysanthemums* may be included if the outdoor seed-bed is not of the best and slugs are likely to be troublesome. Asters are not in the list, as, in comparison with the things already named, they have a short flowering season, and are only admissible in quantity under special circumstances when a brilliant, but brief display is required at a given time. If there is plenty of house room, all these annuals may be sown in boxes, the middle of March not being too soon if an early display is required and there are facilities for pricking off the seedlings into other boxes, pits or frames. Where house room is limited, a bed large enough to take a two or three-light box must be prepared for them, building to a height of 4 feet and treading firmly and evenly to avoid rapid sinking of the bed. The aim being to secure a steady and lasting as opposed to a violent heat, the bed should mainly consist of good Oak or Beech leaves, an occasional layer of stable manure being added thereto as the work progresses. About 4 inches of soil will be sufficient; this should be light, but made fairly firm by pressure with the spade. Several varieties named having very fine seeds, the surface ought to be as fine for these as for *Begonias* or *Gloxinias*. For *Petunias* and the *Nemesia* it is advisable to make a slight depression with a thin pencil, damp the drills thus made, and shake on a little silver sand after sowing. The frame should be shaded slightly if the sun is powerful until the seed has started to prevent the soil drying out, and as soon as the young plants are above ground sufficient air given to keep them sturdy. For outdoor sowing, a good half dozen annuals, bearing in mind that with these also the first consideration is a long flowering season, would be the purple and white Mallows, the latest introduction in the *Linarias*, the best forms of *Godetia* and *Gaillardia*, the scarlet *Linum*, and *Mignonne*. It may be noted that the beds for these should be well dug. It is useless to expect satisfactory results from poor, hungry soil and an ill prepared seed-bed; the latter prevents the seed and plant starting away kindly; whilst if there is no holding power in the soil the plants will be short-lived

and the flowering season proportionately shortened. Having made sure of well prepared beds, the principal point is to thin early and fairly hard, that is in relation to the habit of the different varieties, and a mulching of short manure will be found beneficial while the plants are in a young stage.

**PROSPECTS.**—The advisability of pushing forward in early winter all work in connection with rearranging and planting herbaceous subjects, and indeed all planting matters in which such things figure, was never more apparent than in the present season when the earth has remained frost-bound for three weeks (Feb. 15) and all outdoor work is at a standstill. Even with a break in the weather it will be some time before one is able to work the ground, frost having penetrated unprotected soil rather over 12 inches and gone clean through heavy mulchings to lay hold of the ground underneath. It is, of course, a foregone conclusion that early flowering plants, early *Daffodils*, *Doronicums*, *Hepaticas*, for example, will be very late, and I fancy nearly everything except perhaps autumnal-flowering plants will be affected to a more or less degree. I notice, now that the snow is nearly gone, that the points of the foliage are nipped and scorched, as in *Pyrethrums*, and other things are cut back hard to the old stems, as *Snagdragons*. In all cases, however, the damage done is of a trifling nature, and it should be a strong point in favour of the more extensive planting of hardy flowers that they come so well through a winter when the thermometer for seven or eight nights dropped either to zero or within a few degrees of that point, and this, too, after such incentives to a rank sappy growth in the foliage as were furnished by the wet autumn and mild early winter. It may be urged that the power to withstand the most severe weather would be a natural characteristic of hardy plants, but it must be remembered that there are some included in such lists that have by some means acquired the reputation of possessing a somewhat tender constitution. If these have come well through the February of 1895, they may safely be reckoned perfectly hardy.

**FORCED SHRUBS.**—As a place can often be found for *Staphyleas*, *Ribes*, *Hydrangeas*, *Cerasus*, and other similar things that have done service in the houses, they should be gradually hardened off until they can be planted out. A season's growth is secured if the foliage can be preserved intact without being nipped by premature exposure to frost or biting winds. Nice little breaks can be gradually formed of each variety in front of shrubberies of larger growth, working in an occasional clump of evergreen shrubs to relieve the bare appearance that is a natural result of deciduous shrubs in quantity through the winter months. If the shrubs are planted late in spring, so soon as they are sufficiently hardened a mulching of rather long manure is advisable, and in the case of American plants a little special preparation of the soil.

Claremont.

E. BURRELL.

### PLANTS FOR DRY ROCKERIES.

Too frequently the accumulations of earth and stone or clinkered bricks, as seen in many gardens and referred to as "the rockery," are most unsuitable places for the growth of plants. Those that really thrive are very few, and those that exist merely are by no means numerous. Very often this said rockery was originally a heap of earth, into which a few stones have been stuck without thought and without discretion, and, unsupported by moisture, the plants that are placed thereon either quickly perish or simply drag out an existence. The latter fact is probably due more to planting the wrong things than to any other cause. In reality there are quite a number of useful and beautiful subjects that will do well with only a minimum amount of water, even though they are growing on a sloping bank at an angle of 45° or more. And what is of equal value, many of the subjects I shall presently enumerate only need a very little soil in which to grow when

once they are really established. This latter is perhaps one of the most important items, and to ensure this planting should be done early in the autumn wherever possible. By so doing an opportunity will be afforded the plants to commence rooting before their season of flowering arrives and before the soil is rendered too dry for the rooting process to be a success. For example, it would be wrong on the face of it to attempt to plant such a spot in midsummer with the soil already parched and dry, for at such a time the strongest tufts could scarcely survive the test. In these ill constructed rockeries it is surprising how much assistance can be given to many plants by merely planting them a little on one side and by placing a block of stone over the roots on the more exposed side. This will keep the soil from becoming so intensely dry in very hot weather and preserve a uniform state of moisture and coolness about the roots that will go a long way towards making the whole thing successful. I mention this simple way of dealing with such places because very often the rain has but little effect and watering may as well be left alone, for in both instances the water given only carries with it so much of the dry soil down the sloping bank and on to the path below. I have for the past year or two watched the progress of some plants on raised mounds similar to those described above, and seeing many unsuitable things perish indiscriminately, suggested others with better results. Some of the more important of these plants may be useful to readers of THE GARDEN, who will find in the list given material suitable for furnishing these so-called rockeries and other bare spots which sometimes occur in gardens.

Under the circumstances I cannot name in the first place a genus more worthy as a whole than the *Aubrietia*. Of perfect hardiness, dwarf in stature, and free in growth, these beautiful spring-flowering subjects quickly form carpet-like masses, which are smothered for weeks with their variously coloured flowers. These latter are mostly shades of blue, lilac, violet-purple and red-purple hues, all pleasing and effective in their great spreading masses in spring-time. The ease with which *Aubrietias* are increased and the rapidity that they cover large surfaces are items distinctly in their favour. A goodly companion for these may be found in the variegated form of the *Arabis*, which will brighten by its foliage alone even when its white blossoms are faded and gone. Exceedingly useful, too, are some of the dwarf *Campanulas*, especially those of the *pumila* and *turbinata* groups. The former group are perhaps best, as by placing a few roots beneath a stone or beside it, spreading them out thinly, they emerge in all directions in spring-time, and make a very pretty display in midsummer when little remains to follow. The best kinds are *pumila alba* and *pumilla*. If plants are obtained established in pots, shake the roots free of soil in planting and spread them out carefully. In this way a much greater surface will be furnished than by allowing the plants to spread from one tuft. A similar method may be adopted with *C. carpatia* and its white variety *C. turbinata* and others with equally good results. Not only does this simple contrivance insure the lives of the plants against drought, but it also provides the means of making much out of little; while numbers of plants may be utilised which, under ordinary conditions, would not bear a moment's thought. Another good plant may be found in *Alyssum saxatile compactum*. It provides a sheet of golden yellow blossom which in spring-time and for the purpose indicated is not easily surpassed. This may be had in plenty from seeds. Another yellow-flowered plant may be found in *Cheiranthus alpinus*, which just delights in a comparatively dry rooting medium, and, given this, is much longer lived. Its heads of pale yellow flowers are very freely produced in spring-time. I would like to include the orange-flowered *C. Marshalli*, by reason of its rich colouring, though it is not happy in many soils and does not spread so freely as *C. alpinus*.

Another yellow-flowered and most suitable subject may be found in *Corydalis lutea*, a common

plant no doubt, yet exceedingly charming and graceful withal. It is one of those fine useful plants that one meets in an old abbey garden. On the dry bank or slope, in chinks or crevices of rock, and often emerging from the stone and Moss-covered steps in some old gardens, with barely any soil within reach, this little plant grows freely, and in the border will assume quite a vigorous growth, flowering abundantly and continuously for a long time. The same place will prove a home for some of the *Dianthus* family, and especially such kinds as *deltoides*, *easius*, *superbus*, and others, all of which are very pretty when in flower and of free growth.

Another important family is the perennial Candytufts (*Iberis*), which furnish a wealth of white blossom during the spring months, the best kinds being *I. eorrefolia* and *I. sempervirens*. The *Silenes*, again, are very useful for such spots, notably *S. alpestris*, *S. Schafta*, and *S. maritima* fl. pl. Some of the *Eriogonas* should be also included, and of these *E. macrocarpa* will be the best yellow, and *E. taraxacifolia* among those with white flowers. Besides these there are many more, most of which would prove welcome were they but introduced and established. For instance, *Asperula odorata*, *Saponaria ocyroides*, *Crucianella stylosa coccinea*, *Veronica saxatilis* and *V. pectinata*, *Euphorbia myrsinites*, *Vinca*, *Coronilla*, *Helianthemum* in variety where space allowed, *Gypsophila cerastioides*, *Tropaeolum polyphyllum*, many *Saxifragas* of the crustaceous section, also *Sedums* and *Sempervivums* in variety. Nor must we overlook the value of *Thymus lanuginosus* for such positions. It is indeed an invaluable plant, apparently delighting in the sunniest and most exposed positions, and spreading out rapidly into broad woolly carpets that are pleasing at all times. The plants here given by no means exhaust the list of useful and beautiful subjects, while it contains sufficient variety to provide a lengthy season of bloom in spots too frequently barren and unsightly.

E. J.

#### TENDER & HARDY PLANTS IN THE FLOWER GARDEN.—I.

It matters not into what kind of garden we go (from January to the end of May), whether it be large or small, the bedding plants—so-called—are more often than not an encumbrance in the true sense of the word. An excessive use of tender plants during the summer in the flower garden involves not only a vast amount of labour which might be turned to a better advantage, but it is oftentimes the fertile source of delay in, and what is worse still when the labour is all too limited, the ultimate neglect of work which in the end would give in nearly every instance a far more satisfactory return. Take a case or two as examples of this. If it be a small garden, with one or two hands employed, it is an invariable rule when a gardener takes an interest in his work to have every nook and corner occupied. This is altogether praiseworthy; but take entire stock of the tender plants being prepared for the flower garden and note what an advantage it would be if these were either dispensed with entirely or reduced to a minimum. Probably early Cucumbers and Melons are grown. This fact, in order to make the utmost use of the opportunities, is taken advantage of for the propagation of plants for bedding. In some instances these will foster such insect pests as red spider, also the green and black fly. Any grower of Melons does not need to be told of the nuisance caused by the last-named plant pest. Later on overcrowding is the rule until the happy release comes and the plants are in their summer quarters. Turning to larger gardens, we generally find it to be the rule to encumber the fruit houses with the tender bedding plants as the readiest method of getting over the difficulty. No one will, I think, venture to say that it is desirable to have the fruit houses, in whatever stage they may happen to be, in such an overcrowded condition. The construction of the

houses either facilitates such a process or works in an opposite direction. The necessary work to Vines, for instance, has in some cases to be done under difficulties. At the same time the overcrowded condition renders fumigation more needful than it would otherwise be. When an excessive number of tender bedding plants has to be propagated in large establishments and the room at disposal is not at all adequate to meet such a demand, the plants themselves not infrequently are but ghosts of what they should be. Again, in large gardens there is, where the glass is extensive, quite enough work in other ways than to be overburdened with bedding plants, causing an amount of labour in shifting from one quarter to another that can ill be spared. I must say that I think there is already an improvement going on, however. As in medicine one drug is made to operate against another, so in gardening the same thing is in a measure being carried out, in some cases, perhaps, all unconsciously, but none the less so. I allude to the increased growth of the *Chrysanthemum* as a case in point. In taking up the culture of this, the "queen of the autumn," no one who is a gardener has, I fancy, had additional assistance afforded him. The amount of time required has had to be obtained by "robbing Peter to pay Paul," as the saying goes, and if the first-named does in any case represent tender bedding plants, so much the better, in my opinion, are the results. In the old-fashioned days before so many tender bedding plants were used all the work could be begun and finished in May, the houses at the same time being relieved of the stock required much earlier than has been the case since; this, of course, made it much better for other things.

#### BEDDING PLANTS UP TO AND OF A QUARTER OF A CENTURY AGO.

Reverting for a short space to the plants of that period, it will be remembered by many that *Geraniums* were then all-important features, planting *en masse* of distinct colours being the prevailing fashion. *Verbenas* were also about that time and for some years previously in all their glory; so also were the shrubby *Calceolarias* and the old form of *Ageratum*, tall in growth. Of foliage plants then grown, the variegated *Geraniums* were the most important, the silver variegated and the golden being largely depended on; the bronzes and the tricolors were also steadily coming into use more extensively. *Coleus Verschaffeltii* as well as *Iresine Herbsteri* were likewise being tried as foliage plants (along with *Centaurea caudicissima* and *Perilla nankinensis*, speaking from memory). What is now popularly known as sub-tropical gardening had its birth near about the same time under the elder Gibson when at Battersea Park. I well remember the sensation that it caused when first it was carried out on an extensive scale there. Thence onwards a diversion was made from the ordinary run of bedding plants, but these, instead of being of harder character, were, on the whole, much more tender, whilst at the same time they took more room, relatively speaking, and more heat also whilst stored under glass. *Viola cornuta*, one of the forerunners of the bedding *Violas* of the present day, was then popular; this was a welcome addition, being a comparatively hardy plant. Rollison's Unique *Geranium* had already gone out of fashion, good plant that it is still in many ways. The large number of *Geraniums* then grown occupied a deal of useful space, more so probably than any other kind of bedding plants; instead of diminishing, it increased as new varieties were introduced. Border plants of the same period were much more limited than at the present day. By these I mean those plants that are hardy or tolerably so. Then we had the *Hollyhock* in its full beauty, it is true, the disease to which it is now subject not giving growers any trouble. Hardy herbaceous plants had not come to be known as at the present day, their value then being an unknown quantity to a large extent. The borders of that time were more often than not occupied just for the summer months with

lines of tender bedding plants, being commonly known as "ribbon" borders. More often than not these, when the plants were cut down with frost, were left destitute until the following May—not a desirable feature, certainly. There was about the same time a tendency to enlarge flower beds, or at any rate to make them larger than was really desirable. But, on the other hand, the hitherto prevailing fashion of grouping the flower beds with only paths between them was already going out of fashion, being substituted for others on Grass. It was rather more than twenty-five years back that Nesfield introduced his style of laying out flower garden designs, the outlines being worked in Box edging with the pathways intersected, thus forming separate blocks. Into these narrow paths were usually put coloured gravel, shingle, slate, &c. This style was introduced, if I remember rightly, into the gardens at South Kensington during the early days of the Royal Horticultural Society. To use an American saying, however, "it did not take on" extensively, and in my opinion it was a good thing that it was so. It had no real artistic merit to recommend it; in fact, it was a burlesque at flower gardening more than anything else. In order to get the best view of one of these designs it was necessary to ascend to the roof of the nearest building and then look down upon it. The beds under this system were small and narrow, save the central parts, which were chiefly circles. I once had charge of one of these designs, but never found it to produce a satisfactory effect. I would much prefer an old Dutch garden to one of these geometrical eccentricities.

BEDDING PLANTS OF MORE RECENT YEARS.—One of the greatest innovations in bedding plants within the past quarter of a century has been the introduction of the carpet bedding system, which is, however, now declining, and that to the relief of many a gardener who has had an experience of the time taken up, firstly, in propagation and after-preparation; secondly, in planting out, and, lastly, in the extra amount of labour involved in keeping the beds in order during the summer months. These beds, so to speak of mosaic work, are very well as specimens of enduring patience, as well as of the adaptability of certain plants for the purpose, but the extent to which the system prevailed in due course operated against itself without a doubt. Carpet bedding in all but the most favoured of situations cannot be considered as of long duration. It is rarely that a large amount of it is finished before the second week in June (in fact, I have more than once seen it still hanging about towards the end of the month), and before the following September is ended there is danger of injury to such tender plants as *Alternantheras*. Two thirds or more of the year are thus taken up with housing and propagation. Does it pay? I have personally had a weakness, if I may term it such, for the grouping together of succulent plants after the method of carpet bedding, but less formal in character. The various shades of green, of grey and other neutral tints form a happy combination, but I should not advise the extension on a large scale, the one redeeming feature being that most of the things so used are tolerably hardy, whilst others are quite so. Sub-tropical gardening, already alluded to, was the forerunner of the carpet bedding system, and it has largely survived it; at least I have noted it to be more prominent in many places. Compared with the former the latter makes a better show for the same amount, or even less, of labour expended. The system of giving relief to carpet beds by using plants of light growth affords a welcome change, these dot plants, so to speak, taking off the otherwise flat appearance. The great interest at one time taken in the tricolor *Geraniums* has greatly waned; these have had to give place to even more tender subjects. The one redeeming feature amongst bedding of more recent years has been the welcome introduction of the tuberous *Begonia* into the flower garden. Some of us no doubt can recall the time when *B. bolivien-sis*, *B. Pearcei*, *B. roseolora* and *B. Veitchi* were first introduced into commerce. These

species were the forerunners of the splendid strains of tuberous Begonias now in cultivation, and if the Messrs. Veitch had never introduced any other plants than these or raised other hybrids, there would have been in these facts alone sufficient to hand their name down to posterity. I am fully persuaded that the tuberous Begonia will continue to be one of the finest features in the flower garden for many years to come. Some may say, perhaps, that they are tender plants, but I do not consider them as such to nearly the same extent as many other things, whilst they have one great redeeming feature in that they do not take up any room under glass during the winter months; nor need they do so in the spring to any great extent, for the less amount of coddling they receive the better will be the after results. These Begonias seem to adapt themselves to so varied localities; they are grown well in the south of England, and so they are in the north as well as across the border. I have never seen them luxuriating anywhere to such a degree as in the Lake districts of Cumberland and Westmoreland. Here they were to all intents and purposes quite at home, being one mass of healthy growth and flowers. I saw them thus last July, which proves that they can be got into good condition sufficiently early to secure a prolonged display even away in the north. The raising of young plants from seed cannot be considered a difficult matter, nor do these for the first season, until fit to plant out, occupy much space under glass.

I have already drawn attention to the dotting system amongst carpet bedding plants. Its extended use during the past few years in other descriptions of bedding out has been a welcome innovation. This mixed system can be carried out to great advantage without having recourse to tender plants in any large amount. It has also one decided point in its favour, viz., the plants forming the undergrowth can grow away as they choose without much attention being given to them. I have noted with satisfaction the increased use of Fuchsias in the flower garden, the sturdy-growing sorts of the present day thus showing to good advantage. Several of the species are also admirably adapted for the same purpose. *F. gracilis*, also known under the name of *F. decussata*, should be taken more note of. I have seen it grown as a herbaceous plant in the open border for years together. Sweet-scented flowers or plants have hardly maintained the position which their merits claim for them for several years past; for instance, we see all too little of the Scented Verbena and the Geraniums well known for their fragrance. These no doubt have been supplanted by more showy subjects.

THE PRESENT DAY FLOWER GARDEN—I have noted with pleasure in several instances an increasing amount of attention being turned to really hardy plants. This is as it should be. It should indeed be the chief aim to secure more permanent plants of characteristic features; less dependence will then be placed upon tender plants. A good number of gardeners, and I fancy their employers also, are beginning to tire of the bedding-out system of late carried on. I know as a fact that this is so in some instances, more particularly where it has hitherto been adopted in an excessive degree. On all sides we now hear, if not of actual reductions, at any rate of a tightening of the purse-strings, and if any economy has to be further put into practice, where can it be done more effectually than by dispensing with the more tender and relying upon the more hardy plants? I hope the massing of individual colours in large beds, and the increase still further by too much repetition of one given kind, has nearly died out. The sooner this system has a decent burial, the better for all concerned. No artist would, I think, choose as a foreground to his picture a position which embraced within his vision a mass of scarlet or of pink in an excessive degree. A mere blaze of colour is not real beauty, whilst it must almost invariably pall upon the taste ere long, from the simple fact that it lacks variety, if not from any other reason. What possible advantage there can be in filling

the flower beds with such an excessive amount of any one kind of plant I cannot conceive. The return to hardier plants (for at one time they were the chief factors in the flower garden) should, in my opinion, receive every encouragement. It is not a case in which there is any scarcity of material that can be turned to a good account. The extended culture of the Carnation and allied subjects is worthy of all that can be said in their favour. The same applies to the Rose. Take, for instance, a bed of *La France*; what is there more beautiful or more attractive in the truest sense of the word? Such a prolific flowering Rose as this may with advantage be grown by the dozen. There is, I think, less formality in the flower garden than was the case in bygone years. This, too, is a welcome change, and such a fact ought to be taken into account and be made the most of to introduce plants of hardier constitution. The increased attention to the culture of hardy herbaceous plants is a noteworthy feature. This has been steadily taking root in most gardens, and is still gaining more adherents. Another source which has not so far been made enough of is that of the hardy variegated trees and shrubs, as well as others possessing distinctive features of their own. Then, again, there is a deal yet to be made of the hardy Bamboos and Grasses, which are most appropriate in connection with water scenery. We see a good quantity, for instance, of *Eulalia japonica variegata* and *E. jap. zebra* in pots, but they are quite as well fitted for planting out permanently. The hardy or semi-hardy Palm, *Chamærops excelsa*, is well worthy of extended culture. Bulbous plants, too, of all kinds are being planted more extensively; this is a step in the right direction. The Ivy-leaved Geraniums of the present day are of essential service in the flower garden for vases and baskets as well as for beds; they do not look quite so prim and formal when used for the latter purpose as do the zonal varieties. Their best places, however, are in vases and baskets. The early-flowering race of *Chrysanthemums* are making their way for bedding purposes, thus adding to the variety. Select strains of annuals receive more notice than they did, and they are well worthy of it. *Phlox Drummondii*, intermediate and Ten-week Stocks, *Mari-golds* (French), and the *Tagetes*, *Asters*, and *Sweet Peas* are instances of this. None of these things give much trouble in the raising or after culture. For sub-tropical gardening there is now a fairly good choice without having recourse to the very tender plants raised from seed. The Giant Hemp (*Cannabis gigantea*), the Giant Fennel (*Ferula gigantea*), and the Blue Gum (*Eucalyptus globulus*) are cases in point. The dwarf race of *Cannas* (Crozy's new dwarf hybrids) are proving themselves to be very useful plants. Of miscellaneous annuals which last in beauty for a long period there is also a good choice. *Linum grandiflorum coccineum* (a variety of Flax) I have found to do well both in hot and dry as well as cooler and moist seasons. The blue, the crimson, and the scarlet varieties of the *Anagallis* are excellent for dry situations. In a warm spot *Alonsoa Warscewiczii compacta* thrives well. Another pretty and all-too-much neglected annual is *Nemophila insignis*. Of *Nemesia strumosa* *Suttoni* I am disposed to think most favourably; the past season gave it a severe trial. This year, as during 1892, I hope to see it again in its best condition. *Amaranthus caudatus* (Love-lies-bleeding) is in all respects a grand annual, being well adapted for associating with plants of sub-tropical character. Take a large bed, for instance, as an example of what may be done with a few packets of hardy or half-hardy annuals. There is the Giant Hemp, the taller Sunflowers, the Blue Gum, and the *Amaranthus* in question, to which *Cineraria maritima* might be added as well as the Chilean Beet and *Salvia argentea*. The major portion of these may be sown upon the spot, the only exceptions being the Blue Gum and the *Cineraria*. Other things which never need much room under glass are the *Chamaepeuce* in variety; *Gaura Lindheimeri*, a hardy perennial, but one that is just as good if treated as an annual. *Grevillia*

*robusta* is a useful plant along with *Acacia lophantha*; both should be grown where much bedding has to be done. These are best raised in heat. *Salvia patens* does equally as well if raised from seed as by lifting the old roots; in many places, however, it will be safe in the ground for several days at a stretch provided it is not a wet subsoil. It is a splendid plant for intermixing with other things. The forms of Golden Feather need not take much room in the houses; it is a handy plant, but one that is often abused by too excessive use. Turning to biennials and perennials, the Canterbury Bells (*Campanula calycanthema* vars.) at once claim our notice; so do the beautiful forms of Columbine (*Aquilegia chrysantha*, *A. glandulosa*, and other hybrids being fine subjects). The *Antirrhinum* appears to be somewhat out of fashion, but it is none the less a useful plant. The very fine forms of the *Gaillardia* are most certainly an acquisition to any garden. *Lobelia cardinalis* is a plant worthy of more attention than it often receives. The Red Winter Cherry (*Physalis Alkekengi*) makes a pretty display in the autumn. J. H.

## GARDEN FLORA.

### PLATE 1003.

#### THE THUNBERGIAS.

(WITH A COLOURED PLATE OF *T. GRANDIFLORA* VARS. \*)

A COLOURED plate of the ordinary form of *Thunbergia grandiflora* was given in THE GARDEN, May 27, 1893, and in the present plate this kind is shown on the left, the two most conspicuous blooms being those of its white-flowered variety, which is very uncommon in cultivation. *Thunbergia grandiflora* is a vigorous growing stove climber that will under liberal treatment soon cover a considerable space and then bloom with great freedom. The leaves of this species are about 6 inches long and hastate in shape, while the flowers, which are from 3 inches to 4 inches across, are of a pale blue, lined with a deeper tint, with the interior of the throat almost white. This *Thunbergia* is a very common plant in India, from whence it was introduced into this country in 1820. At Kew it is quite at home in the Palm house, and has been an object of great beauty there as well as on the roof of the house devoted to the Victoria Regia. The white variety I have not seen elsewhere than at Kew, whence it was introduced from India three or four years ago. Being equally vigorous and free-flowering with the type, it forms a good companion plant to it, and for draping or festooning the roof of a large structure these two *Thunbergias* are among the very best subjects for such a purpose. *T. grandiflora* flowers continuously for a considerable time, often from early summer till the autumn.

*T. LAURIFOLIA*—a good deal in the way of the preceding—was also the subject of a coloured plate in THE GARDEN for September 25, 1886. The most marked difference is in the foliage, which is ovate in shape and, as suggested by its specific name, somewhat like that of a Laurel. It is equally free growing and free flowering with *T. grandiflora*, and, in common with that species, needs a large structure for its full development. It is also a native of India and was introduced in 1856. Besides the specific name of *laurifolia* it is also known under that of *Harrisii*. All of the above may be readily propagated by cuttings of the young growing shoots taken in the spring. For this purpose weak or medium shoots should be chosen in preference to the very strong ones.

\* Drawn for THE GARDEN by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by Guillaume Severens.

**T. ALATA.**—While a large structure is necessary for the development of the *Thunbergias* mentioned above, this occupies but little space, and it may also be grown in less heat than the others. Though a perennial, it is often referred to as an annual, and succeeds well treated as such, the seeds being sown in early spring, and the plants so obtained will flower the following summer. There are several varieties of this differing from each other in the colour of their blossoms, but all alike in other respects. Among them are white, yellow, orange with a dark eye, white with the same, a self-coloured orange, and others. This *Thunbergia* may be used for many purposes where small-growing free-flowering climbers are admissible. It is also a capital subject for hanging baskets, and in a greenhouse temperature it will during the summer flower well.

**T. FRAGRANS**, which at one time Messrs. Veitch used to grow so well, is a slender-growing climber, with oblong shaped leaves cordate at the base and about 3 inches long. The flowers are 1½ inches in length, pure white and borne in great profusion for a considerable time.

Included now-a-days in the genus *Thunbergia* are the plants at one time known under the generic names of *Meyenia* and *Hexacentris*, the most commonly met with of these being *Meyenia erecta*, which forms a much-branched bush, whose purplish-blue blossoms, lit up by an orange coloured throat, are borne for many months of the year. It is a native of West Africa, and was introduced in 1857.

**T. MYSORENENSIS**, which used to bear the generic name of *Hexacentris*, is a very striking subject when in bloom. The flowers, which are borne in long pendulous racemes, are of a peculiarly curved shape, and in colour red and yellow.

For a more detailed account of the genus *Thunbergia* the reader may refer to *THE GARDEN* September 25, 1886, when the coloured plate of *T. laurifolia* was published. H. P.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**LATEST SEAKALE.**—The later a supply of Seakale can be kept up this season the better, all early crops being later than usual, and a scarcity amongst vegetables generally in early summer being inevitable. Where old stools, covered some time ago with pots and leaves are commencing to grow, and there still remain in the open ground any yearling crowns, every other row may be taken up and forced, or laid in under a north wall and covered with a foot of leaf-mould to come on gradually, and the crowns in the remaining rows covered with flower-pots and mounded over with soil from the intervening spaces. Thus treated, growth will be very gradual, and a supply afforded after the latest litter-covered permanent beds have been cut over. Some growers earth up their latest batches with ashes or leaf-mould, but the former often make the Kale dirty if the weather is wet, and through both the ashes and leaf-mould growth often pushes, and, becoming green from exposure, is hardly fit for the dining-table. Where roots from forced crowns have been cut into lengths for cuttings and have not the advantage of frame protection, but are laid in under walls, they must be examined after the thaw, as the soil often sinks, leaving them insufficiently shielded against later frosts. Nothing surpasses leaf-mould for covering, as it is warm and encourages early sprouting from the callused portions, and being porous allows the rain to pass away freely. Those who have not yet tried the Lily White variety should do so this season. It is especially useful for successional work, and is of a remarkably delicate colour and good flavour. The ordinary variety is best for early forcing, as it responds more quickly to heat. Ground for the reception of root cuttings to produce crowns for

early forcing next year, and which will be planted out in April, should be prepared as soon as possible to allow of settling. As a rule, I do not advise much rich manure to be dug in for this batch, spent Mushroom manure being preferable, several waterings with liquid manure during the summer being given. A warm sunny aspect should also be given. Strong manure, which induces a prolonged growth, is more suitable for batches which are not to be forced so early.

**ESCHALLOTS.**—The sooner in the month the plot intended for these can be got into a dry enough condition to allow of drills 3 inches deep being drawn the better, as if once covered with soil slight frost will not hurt them, and Eschallots prefer a long season of growth. As a rule this crop is grown under favourable conditions between rows of fruit trees or close by the margins of walks where the soil lacks richness. It is astonishing to what size individual bulbs of Eschallots will attain to if given a rich soil and sunny position. If the rows are about 1 foot apart and the bulbs themselves 6 inches, a mulch can then be given during dry weather, and overhead waterings of liquid manure occasionally. On heavy soils it is well to plant on raised beds, incorporating sufficient opening material to prevent basal rot and hand-weeding the beds during summer, as in the case of Onions. Mulehng in that case must not be practised, but broadcast sprinklings of some good rich fertiliser applied twice during the summer and in showery weather.

**JERUSALEM ARTICHOKE.**—Where these were not lifted by December and stored the late extreme frost will probably have proved too much for the tubers. The sooner in March the young off-sets which were separated from the eatable portion when lifted are planted the better. The ground need not be very rich, as if over-stimulated, tall stout stems and a superabundance of foliage follow at the expense of the crop. If, however, they have to be planted on the old site, good manure may be used, as overgrowth need not be feared. Sufficient room should be allowed between the rows to allow of the sun's rays gaining admission, from 15 inches to 18 inches being a good distance and 9 inches between each tuber.

**GLOBE ARTICHOKE.**—In many places these will have entirely succumbed, especially where mulching was not given in time or where this consisted of manure in a too advanced stage of decay. In a former calendar I advised an examination and a renewal of the protecting litter where necessary. This must now be removed, leaving only a small quantity round the bottom. All decayed leaves and stems should also be removed and the soil pricked over with a five-tined fork, some approved fertiliser being afterwards applied. Where blights have occurred they must be made up with off-sets from the parent stools. Seedlings are, as a rule, useless. Any off-sets that were severed from the old stools and potted up in autumn, being since then protected by frames, may be planted out on well-manured ground towards the middle of the month and afterwards mulched with short litter. Where there is plenty of room to spare 6 feet is not too far apart for Artichokes.

**TRIPOLI ONIONS.**—Early in the new year I advised going over beds of winter Onions and firming all those which were loosened by the high winds. Those who did so will now find the benefit of the practice. I have been looking over our own today and find that those most damaged by frost are loose at the base, being quite soft and decayed at that point. Rows that were only moderately thinned in autumn may now have their final thinning, those drawn out being planted on well-prepared ground in rows 1 foot apart and 6 inches apart in the rows. These will be rather later than the bulbs not thinned and form a good succession. Where young Onions are in demand for salading, a short row or two may well be left unthinned, these being drawn as required. I find the Trebon a capital Onion to sow in autumn, as it stands well in time of severe frost; indeed, better than most of the Tripoli section; bulbs in well in July

and is of fine mild flavour. As soon as transplanting is completed the Dutch hoe should be put through the beds and a moderate application of soot and guano given.

**SPRING ONIONS.**—In many instances the sowing of this important crop will be late this season, but the very first chance must be taken to get in the seed. Where the ground was prepared early in the year the principal preparation will consist in well scuffling the surface to the depth of several inches. This is best effected by five-tined forks. In addition to the soot incorporated at trenching time another good coating may be laid on before scuffling is commenced. This will aid in warding off attacks of the dreaded grub. By no means tread on the ground when in a wet or sticky condition; better by far wait a week or ten days longer. Where the ground has now to be prepared I would advise a departure from the ordinary method of trenching. Take out an opening to the desired depth at one end of the plot, wheeling the soil to the opposite end, and after spreading on a good thickness of semi-rotten manure, soot and wood ashes, proceed to throw forward the soil into the opening, well mixing in the ingredients as the work proceeds. By this means the Onions get the benefit of the manure from their infancy, which is just what they require. Although Onions require a firm surface, many mistakes are made in solidifying the ground. I have sometimes used the garden roller on light soils with advantage, but on heavy ones the practice may be ruinous, as the surface is so sealed up that neither air nor heat can penetrate, and where the bed is on an incline rain often runs away to waste instead of entering the soil. As a rule I prefer thorough treading to any other method, this being first done after the ground is levelled and before sowing the seed, repeating it when this is completed and treading first lengthways and afterwards crossways. A fine day should be chosen for sowing, the drills being drawn and allowed to stand an hour or two to dry before sowing. A foot apart is a good distance for the rows, although where ground can be spared 15 inches is a better distance. Thick sowing is ruinous, as during thinning so many of the seedlings are loosened, and never do so well after. This year, however, owing to the unsatisfactory condition of seeds in general rather thicker sowings ought to be made. Sowing completed, a covering of wood ashes should be given before the drills are again filled in. For early use the smaller bulbing varieties, such as Nuneham Park, Bedfordshire Champion, and Main-crop, are preferable, while such as Ailsa Craig, The Wroxtan, and Cranston's Excelsior, which continue to grow on later in the season, are all good sorts. Where Onions are preferred to Shallots for pickling, the small Silver Skin is about the best to grow for the purpose. These at thinning time may be left almost touching one another. If any spring varieties are being raised in heat for producing exhibition bulbs and the ground has not yet been prepared, it must be done at once. About the middle of the month any bulbs of choice varieties intended for seed should be planted out in square plots, so that they can be supported as growth proceeds.

**CELERY TRENCHES.**—These may be taken out as soon as opportunity offers, as then the intervening spaces can be utilised for planting out such things as Lettuce, Cauliflower, and Cabbage raised in heat. The manure also has then a chance to get into a good condition before the Celery is planted, supposing it to have been green when dug in. There is a prevailing idea that too much or too strong manure cannot be given to Celery, but this is a mistake, as a gross, sappy growth at the start means the same at the finish, such being prone to disease and rot and entirely void of flavour. I have had excellent results from the use of Mushroom manure, this inducing a hard and medium growth, which admits of being fed at intervals without the least fear of evil results. Wherever practicable plant in narrow trenches capable of holding only one row, these being better in every way than wider ones

for holding two, three, or more rows. In case of scarcity of ground wide trenches are unavoidable.

J. CRAWFORD.

### FRUIT HOUSES.

MELONS.—For early forcing of Melons I advise pot culture, and to get the best results have strong plants at the start, which should by this date be well up the trellis. They will soon require stopping to induce lateral growth. With pot plants it is not well to lose the first show of fruits after the stopping, as perhaps only two or three fruits may appear on the side or lateral growths. Where early fruits are desired two fruits will be better than four smaller ones a month later, and there will be no loss, as the crop, if cleared off quickly, will give room for a later one which will give a greater weight of fruit. If the plants have plenty of bottom-heat there will be less difficulty in swelling the fruits. Failing bottom heat by hot-water pipes, it is well to add new fermenting material to the old as soon as a good set is secured. As growth increases food may be given at every alternate watering in the way of tepid liquid manure and the surface roots top-dressed with rich soil and manure. More care will now be necessary to prevent cracking or decay of stem so prevalent with these plants. Some varieties are much worse than others in this respect. Those who have poor houses often suffer, and specially when a large body of manure is used. I find that the plants suffer much less when grown in pots if these latter are on a firm base. With careful watering and keeping the stems dry a sturdy growth results, and should decay appear cover the affected part with finely powdered charcoal with a small quantity of fine sulphur. Temperatures may be raised, that is as soon as a good set is obtained, 70° at night in mild weather being allowed and 5° to 10° higher by day. On cold, windy, sunless days 75° may be the maximum, as it is not wise to overheat the pipes. As we often get brilliant sunshine for a few hours daily this month, allow the thermometer to run up freely, as warmth by sun-heat is most beneficial. Give air sparingly and close by 1 p.m. to get full benefit of sun-heat.

SUCCESSION MELON CROPS.—Many cannot spare space for the earlier plants advised above, and commence to grow their first crop at the end of February or early in March, thus securing strong plants. Seedlings can be raised with less difficulty now than earlier in the year. Sow the seed in small pots, which should be placed in bottom-heat, sowing a couple of seeds in a pot and removing all but the strongest. For early summer use select a thin-skinned variety with a sturdy habit, not a long-jointed kind, as I find that the latter are not so reliable. For this purpose such varieties as Ganton Orange, Beauty of Syon, Blenheim Orange, the old Golden Perfection, and Eastnor Castle are noted for their free setting and early fruits; but in these days, when most growers have their own selections, it may be out of place to advise as to any kind, as the varieties are so numerous. If quality in these fruits be the aim of the grower, he will do well to keep to one kind in a house, as these fruits are fertilised so readily by insects that they get much mixed. A good Melon soon deteriorates when others are grown with it. Those who have modern Melon houses will not need much advice as regards the welfare of the crop. When the plants are started and due attention is paid to temperatures, there is less trouble than earlier in the year. The bed or rooting material should be prepared when the seed is sown, as then the soil will be in suitable condition for planting. Melons like a heavy loam or clayey soil, but not in great quantities, the best results being secured by a small root space, with liberal surface supplies of food, a narrow ridge or heap to each plant. If the bottom heat be manure, I would advise having slate or tiles of some kind under the soil that is on the manure, as this prevents the roots going into the manure. The soil when placed in position should be made firm, and plant at 30 inches apart. Plant firmly, staking and watering sparingly at the start. Also syringe

freely as growth is made, and stop the main shoots when the plants have reached the space desired or at the top of the trellis. Keep them free of growths up the stem till the trellis is reached, stopping as soon as they appear. As the lateral growth forms after the leader is stopped, tie in those well laden with fruit and stop at the third or even the second joint if the fruits are close to the plant, and endeavour to set the first fruits that show, treating as advised for early plants.

EARLY STRAWBERRIES IN POTS.—The early plants placed indoors in December or early January will now be at a critical stage. Some of the Vicomtesse H. de Thury section will be in full bloom and others just on the point of opening. Plants that have set their flowers should be removed to shelves as soon as sufficient fruits are set; indeed, they may be transferred just before they flower, as then there is less check. A drier atmosphere can be maintained and the flowers can be readily fertilised, this latter being done about mid-day when the pollen is dry. By removal to shelves with a freer circulation of air the stalk lengthens and the plants absorb more moisture. As soon as from nine to twelve fruits are set it is well to give more warmth and air, especially early in the day. When the sun is bright give tepid liquid manure freely and thin early, as the sooner those fruits left to mature are given all the energies the plants possess they will be larger and of better shape. As regards the number of fruit each plant should carry, much depends upon the strength of the plants, the variety, and if forced hard, from eight to ten fruits are ample if size and quality be desired. A few of the most forward plants of Vicomtesse Héricart de Thury may be given a warmer house than is usually advised, as this variety forces well in a Cucumber or Melon house on a shelf if syringed overhead freely, and a dish or two of fruits in advance of the first lot brought on more slowly will be appreciated. The above variety is one of the best to force hard if the fruits are set before placing in a forcing pit. When the early forced plants are colouring freely they will repay removal to a cool drier house. I have a small house devoted to these fruits for finishing, and the flavour when treated thus is little inferior to fruit gathered from the open; besides, there is a great gain, as the fruits keep longer and swell better. As the ripening period approaches manures must be omitted and the water at the roots be restricted if given a cool house, but dryness will produce sour fruit. After the fruit is gathered the early plants will be excellent as autumn fruiters if shelter in cold frames can be given for a time, when the plants can be planted out in May, giving them ample supplies of moisture when required. Vicomtesse H. de Thury is an excellent variety for fruiting in September if saved after forcing and planted in rich soil at time named.

SUCCESSION CROPS.—There will now be less difficulty in forcing these, and I find such varieties as the new Royal Sovereign, La Grosse Suerée, Anguste Nicaise, Keens' Seedling, President, and Sir Chas. Napier are all excellent for succession crops and are forced in the order named. Royal Sovereign did splendidly last season and looks promising this. La Grosse Suerée is excellent for home use, but not so good for packing, and the value of this variety is its good cropping, with noble looking fruit. Before introducing Strawberries where they are to be forced, remove all decaying matter, cleanse, and give a thorough soaking of water. For succession crops, such the best results are obtained by slow forcing, so that if fruits are wanted for a certain date, allow a week or two longer than the time required, as by slower forcing better results are secured. The advice given above as to finishing the fruits is of equal importance for later crops. With more sun the plants will now absorb more moisture, and I find it is excellent to give an occasional watering of liquid manure before the plants flower, as this strengthens the spike, but once a week will suffice. On the other hand, I do not top dress, as often advised. Many plants are ruined at the flower-

ing period by green-fly, and this pest multiplies rapidly at this season, so fumigate every fortnight up to the time the plants are in bloom two nights in succession. By this means it will not be necessary to fumigate so strongly at one time. Frequent syringings overhead will maintain a healthy leaf-growth, and by shutting up early and damping overhead freely there will be little trouble with red spider, one of the worst pests Strawberry forcers have to contend with. After the fruits are set the flies are not so harmful, one or two good fumigations generally being sufficient. Plants required for later crops that have been wintered in houses or frames should not suffer for want of moisture. If in dry fruit houses, water them overhead freely. These plants should never be dry at the roots, and if in a dark place, lose no time in giving more light, as the trusses will be weakened if not freely exposed as the sap is on the move. G. WYTHES.

## DESTROYERS.

### FLOWER GARDEN PESTS.

THE pests in a flower garden are almost as numerous as the flowers themselves; nevertheless, there are some kinds which are much more injurious than others. Last year, as far as my experience goes, our gardens suffered comparatively little from injurious insects, with the exception of earwigs, which were more than usually troublesome and abundant. Of all the insects, perhaps, which do the most damage in gardens the various kinds of aphides, which are commonly known according to their colour, as green or black fly, I think stand first, not only from the amount of injury they do to plants by sucking the juices of their leaves and tender stems, or by their dropping the honey-dew which they secrete on to the leaves, and thus choking up their pores, but also from the very large number of plants which they infest. In fact, there are few which do not suffer more or less from the attacks of some member of this family. Those, however, which belong to the natural orders Funariaceæ, Gentianaceæ and Iridaceæ are said to be entirely free from them, and labiates and cryptogamic plants nearly so. One of the peculiarities of these insects is the extraordinarily rapid manner in which they breed, a plant being apparently free from them one day and a few days afterwards being completely smothered by them. This is not quite so strange as it seems at first sight, when we realise that an aphid will give birth to two live young ones within the space of half an hour, and that these young will probably begin in the course of three or four days to increase their species at the same rate.

One of the commonest species is the well-known green-fly of the Rose (Siphonophora roseæ). Few if any Roses are exempt from their attacks, but the Tea-scented kinds generally suffer less than the others. Dahlias, Verbenas, and Asters are also infested by this species. In seasons which are favourable to this insect it seems almost impossible to keep Roses out of doors free from them, as these insects breed so very fast. The most important thing is to take steps to thoroughly clean the plants as soon as any are detected on them, on the principle that "a stitch in time saves nine." Plants almost without number have been suggested for keeping this insect in check, but there seems to be no royal road to the accomplishment of this end, and whatever means we use must be persevered in until we accomplish our object. If only one plant is infested and that not to any great extent, brushing it where the insects are

with methylated spirits of wine, benzine, or water in which paraffin oil has been mixed at the rate of one wineglassful of oil to four gallons of water is very efficacious. When a more general application of some insecticide is required, syringing the plants or spraying them with one of the various forms of spraying machines is the best remedy. These machines, though more expensive than a syringe, are far more economical as regards the amount of insecticide used, and it likewise applies the liquid in a more uniform manner. When dealing with aphides, it is important to use soft soap, or something of a greasy nature, in order that the fluid which is used may not run off them like water off a duck's back. One of the simplest and most efficacious remedies is the extract from 3 lbs. to 4 lbs. of quassia chips, 2 lbs. of soft soap, well mixed together, and added to 50 gallons of water. Another very good remedy is dilute paraffin emulsion. This is made by mixing together a pint and a half of condensed milk and 3 pints of water, then add 1 gallon of oil, and churn them until the whole solidifies and forms a kind of butter. This butter should be diluted with from twelve to sixteen times its bulk of water, and should then be used at once. The chief drawback to using paraffin in any form is to prevent it separating from the water and rising to the surface. When this happens it will either be applied too weak or too strong, but when the paraffin is made into an emulsion there is little chance of this danger, as the ingredients are so thoroughly mixed. Another very useful recipe is, to 7 lbs. of tobacco add 1 lb. of soft soap, and boil them well together in 5 gallons of water, and then strain the mixture, and to every gallon add 36 gallons of water before using. The natural enemies of the green fly are numerous. The grubs of the common lady-bird, of the lace-winged flies, and of a very common fly with a black and yellow-banded body, which may often be found hovering in the air near trees in gardens on sunny days, and there are various birds which devour them. Perhaps their greatest foes are certain small parasitic flies nearly allied to the ichneumon flies which lay their eggs in them; the grubs hatched from these eggs kill their hosts by feeding on them.

Thrips is another very common pest, which is, however, as a rule, more injurious to plants under glass than to those in the open air. They are not so very easily detected as they live on the undersides of the leaves. They may be destroyed by the same insecticides as green-fly, besides which 2 ozs. to 3 ozs. of Gishurst compound to a gallon of water, with a little tobacco water added, is said to be a very deadly remedy. Though thrips do not breed in such an extraordinarily rapid manner as aphides do, still it is very essential to thoroughly cleanse a plant as soon as it is found to be infested.

Earwigs are another very troublesome pest. Dahlias, Chrysanthemums, and Carnations are their principal victims in the flower garden. The only practicable way of destroying them appears to be by trapping them. The best traps are pieces of crumpled-up paper put into small garden pots or the hollow stems of Beans, Artichokes, or Sunflowers; the latter are particularly useful, as they contain a certain amount of a sweet lining to the hollow stem. These traps should be examined every morning, and the person who undertakes to empty them should provide himself with a bowl partly filled with water on which some paraffin oil has been poured, so that the insects when shaken into it will be soon killed. The earwigs may very easily be blown out of the hollow stems into

the bowl. The traps should be placed near the flowers so that the insects may easily find them.

G. S. S.

## STOVE AND GREENHOUSE.

### STRIKING CUTTINGS.

ON p. 58 is pointed out the advantage of propagating one's stock of Chrysanthemums from plants that had been grown naturally rather than from those that had been highly fed, even though the shoots of these last might be stouter than the others. The writer quotes an instance that has come under his notice in proof of that assertion, and with the entire article I thoroughly agree; indeed, I should be inclined to go much further and apply the remarks not only to Chrysanthemums, but to plants in general. It will be found in the case of all plants that have been developed under the stimulating influence of any of the highly concentrated manures now in such general use that their progeny, though bulky in appearance, are wanting altogether in the stamina necessary for building up a permanent healthy specimen. Such subjects as Pelargoniums, Heliotropes, Fuchsias, Petunias, and other plants of this nature will not grow kindly if propagated from overfed parents. In another respect, too, this high feeding appeals strongly to the propagator, and that is the cuttings from such plants are far more difficult to strike than if they are produced on plants that have not been so heavily manured. This was brought prominently under my notice some fifteen years ago or thereabouts, when the white-flowered Bouvardia with double blossoms, Alfred Neuner, was first sent to this country. As large a stock as possible in a short time was the object aimed at, and the first two or three crops of cuttings from the imported plants struck root readily enough. Then just as the plants commenced to push out other shoots, a pinch of concentrated manure was given with the object of hastening growth, which succeeded perfectly, but at the same time another stumbling-block arose, for when the shoots so produced were taken as cuttings, many altogether failed to root, while those that did strike stood a long while before doing so. Since then I have tried many experiments in striking cuttings, all of which have pointed to the fact that cuttings from overfed plants are not only far more difficult to strike, but even when rooted they are often less satisfactory than those propagated from plants grown in a more natural manner. Many instances have come under my observation of late years, not only in my own practice, but also in that of others. One case which I particularly noted was an attempt to work up a large stock of *Coprosma Baueriana variegata* from comparatively small beginnings. The cuttings of this were struck, potted off, and as soon as sufficiently large the tops of the young plants were taken as cuttings. This went on until a considerable number was obtained, and one day a large batch of cuttings was taken which, though treated the same as had always been done before, refused to root, or at all events very few did so in a satisfactory manner. I was consulted on the matter, and a few inquiries elicited the fact that the young plants had all been given a pinch of fertiliser to force on the production of shoots, which so far succeeded, but finally resulted in greatly checking the increase. It was quite six months before these young plants resumed their normal state, and propagation went on as before. Even in the case of plants that have not been unhily fed the stout succulent shoots do not strike root so readily as the weaker short-jointed ones, and this fact should be especially borne in mind when the subject is difficult of increase in this way from whatever part of the plant the cutting may be taken. For such things the best cuttings, as a rule, are furnished by the side shoots that have been well exposed to the light and not those borne in the centre of the plant. Of

course, in the case of plants with a decided leader such as *Arancarias* cuttings of the side shoots are useless, as they never form a symmetrical specimen. Of hard-wooded plants, some of which are notoriously difficult to strike, it will be often found that the best results are obtained by those near the edge of the pot, and when covered with a bell-glass I have often noted that should a cutting or two be pressed down by the edge of the glass it will be rooted before any of the others. T.

**Libonia floribunda.**—At this season of the year large specimens of this plant, 2 feet in height and as much through, with healthy, dark green foliage, and covered with tubular blooms of vermilion and yellow, are among the most striking occupants of the conservatory. The *Libonia* is at present, unhappily, quite out of fashion, it being a rare thing now-a-days to see it really well done, but there are few subjects that fill the gap in blooming plants during the first three months of the year so satisfactorily and enduringly, provided adequate attention is accorded. Its great enemy is red spider, and an arid atmosphere during the summer invariably induces an attack of this pest. Cuttings should be struck in heat, a propagating frame for choice, in February, potted as soon as rooted, and shifted on during the spring and early summer, taking care that the shoots are well stopped to lay the foundation of a bushy and symmetrical plant, after which they may be stood in a frame until October, when they should again be housed. During hot weather the foliage should be kept healthy by frequent syringings, which is a *sine qua non* that is seldom observed, the neglect of this practice resulting in the leaves being scanty and of an unhealthy hue, as is the case with the majority of plants one sees. Large pots should not be used, but nutriment in the shape of liquid manure and soot-water applied at frequent intervals. The system of planting out during the summer is not recommended. Large specimens, that at this period are most valuable for effect, can be grown from the cutting in three years, but year-old plants, when well flowered, are very effective. Fibrous loam and sand with the addition of a little peat form a good potting medium.—S. W. F.

**Roman Hyacinths.**—I, too, have found the blooms of Roman Hyacinths exceptionally numerous and of fine quality this season. The general plan of preparing the bulbs for forcing is to plunge them in cocoa nut fibre refuse, ashes or sand for a period of six weeks or so after potting, with the view of encouraging a free root action. This plunging is not at all necessary. If the bulbs are planted rather thickly in ordinary Geranium cutting boxes, exposing the crown or neck of the bulb, and standing out of doors without any protection from rain whatever, only covering them in the case of frost, equally satisfactory results will be attained.—E. M.

**Poinsettias in summer.**—After many years' experience I have come to the conclusion that dwarfer and better plants generally of this fine winter-blooming subject are produced by frame or pit culture from the end of May to the middle of September than when they are kept growing in intermediate or even cool houses. In the former quarters growth invariably becomes leggy and soft, while the foliage is under-sized. In cool houses the temperature fluctuates too much to suit Poinsettias. The plants enjoy a quiet moist atmosphere with plenty of air, but no draught. This is best afforded in pits and frames, the plants standing on a cool ash bottom. One thing, however, is necessary, namely, closing the frames each afternoon so as to husband a little sun heat. The pots should be well drained, as the roots of Poinsettias are very impatient of too much moisture. More so is this the case towards autumn, as the nights become cooler. After housing, a temperature of 60° or 65° suits them well, and a stimulant of a mild character is beneficial two or three times a week. The most remarkable batch of young Poinsettias in a growing state I ever saw was at Carrow House, Norwich, the residence of Mr. J.

J. Colman. It was at the beginning of September, 1893. The plants, planted out in a brick pit and treated in the manner above described, were a picture of health and vigour, having stems of great thickness and extra large leaves. On asking Mr. Jones, the gardener, how these plants behaved when lifted, he replied, "by being kept close for a week after potting only a few of the very lowest leaves fall off, and we get excellent flower-heads."—J. C.

**Nertera depressa.**—In summer when this interesting little plant is thickly set with its bright orange-scarlet berries, it is sure to attract attention. It is quite an exceptional plant in its way, possessing little or no beauty except when its berries are so brightly coloured. Years ago I grew hundreds of this plant in small pots which met a ready sale when the berries were ripe and coloured. As the plant flowers early in the year, it is best increased by division at once, so as to encourage an early growth and a greater number of blossoms. These latter are of a greenish hue, and appear in the axils of the leaves. The plant grows freely in light, sandy loam, with fine brick rubble added liberally. In potting keep the plants on a level with the top of the pot, so that a mound-like form may result when growth ensues. Afford plenty of moisture overhead during the growing season. For general work 5-inch pots are a very useful size to employ, though pans of larger size are also very effective. It may be well grown in a cold frame, and in such I have wintered many hundreds of plants with impunity.—E. J.

#### LISIANTHUS RUSSELLIANUS.

WHEN looking over the seed-growing establishment of M. Ernst Benary at Erfurt two or three years ago M. John Benary exhibited with conscious pride a houseful of *Lisianthus Russellianus* in full flower and in splendid condition. They were grown to produce seed, and the profusion of bloom was admirable. I have to go back to the year 1851, when similar plants in flower were grown by Mr. Green, of Cheam, Surrey, who exhibited them in London previous to or about that time. Mr. Green exhibited a plant with five hundred blooms expanded on it. None of M. Benary's plants were equal to this fine specimen, but it showed what could be done by well-directed skill and attention to details. I was so impressed with the beauty of this plant some thirty years ago, that I purchased a packet of seed and raised a fine lot of plants from it. It is a biennial, and the seed costs about a shilling a packet. The flowers are in form like a small Tulip and of a distinct violet-blue colour, so that the beauty of a plant with five hundred fully expanded Tulip-like blooms each of a violet-blue colour—may be imagined by those who have not seen it. These old flowers are to many young gardeners practically unknown. It is a larger genus than many persons are aware of. There are upwards of fifty specific forms enumerated in the "Index Kewensis," some of them, of which figures are extant, being of no great beauty. *L. pulcher* is a distinct and rather beautiful species which I have not seen in flower, but it is well figured in the *Botanical Magazine*, tab. 4424, from a good plant grown in the hothouse of Messrs. Lucombe and Pince, of the Exeter Nurseries, in 1848. Seed was advertised of it some years ago, but I failed to get any plants from it. The plant has a near resemblance to a scarlet Pentstemon. *L. Russellianus* is also well figured in the *Botanical Magazine*, tab. 3626, and there we gather that it was sent home from Texas by Drummond in 1835, who says it was "not excelled in beauty by any plant." It was named in honour of the Duke of Bedford, who at that time was a great patron of gardening.

I used to grow annually two score or more of these plants in 9-inch pots, and they were very valuable for furnishing the greenhouse in the month of August. The seed may be sown in April to get good strong plants. It is small, and should be sown on a smooth surface and just covered with fine white sand. It vegetates in any forcing

house with a temperature of 55°. A square of glass is laid over the mouth of the pot or seed-pan to keep the soil in a moist condition. Prick the plants out in small pots as soon as they can be handled, to be planted one into a pot later. About the end of August they will be large enough to repot into 4 inch or 5 inch flower-pots, and as the cold weather comes on they must be placed in a heated house. I have always wintered my plants on a shelf near the glass roof in a temperature of 55 to 60°. They do not require much water in winter, and what they do need is applied to the roots by dipping the pots in water, so that it moistens the soil through the hole in the bottom of the pots. Drain the latter well, and grow the plants in good yellow loam and fibrous peat in equal parts, a fourth part of decayed cow manure and coarse sand to keep the compost open. Repot them in February into 7-inch flower-pots, and as soon as they are well established, which will be by the end of April, they may be repotted again into 9-inch pots. Mr. Green grew his large specimens in 18 inch pots, which are needlessly large and most unwieldy objects to move about from one place to another. As the plants grow they must have the points pinched out of them. Careful watering is also necessary at all times, especially in winter, as many of them have a tendency to die off at the neck. In summer they do well in any unheated house or pit, such as they were growing and flowering in so well in M. Benary's seed grounds at Erfurt.

J. DOUGLAS.

**Rhapis flabelliformis.**—Of some Palms, such as *Kentias*, *Arecas*, *Latantias*, *Cocos* and *Phoenix*, large quantities of seeds are sent to this country, and being grown for decoration they are met with almost everywhere; but seeds of this *Rhapis* are rarely to be obtained, hence it is usually increased by division, which can be successfully carried out in the case of this Palm, as, unlike most of its class, suckers are produced pretty freely. If the operation of separating them from the parent plant be carefully carried out, the loss will be but slight, though the *Rhapis*, like all other Palms, resents being disturbed at the roots. It is a good plant for the dwelling-house if kept clean, which last item is very necessary, as the leaves are rather rough and the dust adheres more readily to them than to many other Palms. This *Rhapis* is a native of Japan and requires only greenhouse treatment; therefore it may be employed in positions that are too tender for more delicate subjects. Though a greenhouse is all that is necessary for their well-doing, yet the young plants will make more rapid progress if given the heat of a stove. A miniature form known as *Rhapis humilis* is a charming little Palm, but needs rather more heat and attention than the stronger grower. I have seen a form of *R. flabelliformis* with variegated leaves, but it often shows a considerable tendency to revert to the normal kind.—H. P.

**Azalea obtusa.**—This is a very pretty little Azalea, which by some would be preferred to the larger-flowered forms, though to many the production of very large blossoms is the one object to be aimed at. *A. obtusa* forms a dense, freely-branched little bush, clothed with leaves somewhat larger than those of the well-known *A. amena*, while the flowers are also of increased size. In colour they are a kind of orange-red. There is also a variety with white blossoms, which doubtless originated as a sport from the typical kind, as occasionally a red flower will make its appearance among the white ones, and still more frequently some of the white petals will be more or less striped with red. This Azalea is without the hose-in-hose conformation of the flower so conspicuous in *A. amena* and some other of these small-flowered forms. It is particularly noticeable in *A. calyciflora*, for in this the calyx segments are enlarged and coloured the same as the flower, thus presenting exactly the appearance of one flower within another. *A. calyciflora* is, except in the double blossom, so much like *A. obtusa*, that in all probability it is but a variety

thereof. All those above mentioned, as well as *A. amena* and the various hybrid forms claiming parentage from it, force readily, and after they have been treated in this way for two or three years they may without difficulty be had in bloom by Christmas. Azaleas of this class strike very readily from cuttings, and plants obtained in this way are much preferable to those propagated by grafting, as they are naturally of a dwarf, bushy habit, and are totally out of place stuck on a long naked stem.—T.

#### MONOTONY IN GARDENS.

PERHAPS the most grievous source of wasted effort in gardens is monotony arising from everybody growing what his neighbour grows, so that we lose many chances of variety. Thus it comes that the nurseryman who grows new or rare trees or shrubs often finds them left on his hands, so that many country nurseries only grow a few stereotyped things, which means monotony to gardens. For instance, we see public gardens and squares in London given over to the common Privet, the neglected Lilac, and the common Elder, as in Lincoln's Inn Fields. The temptation is strong on the part of trade growers to keep only things that people want to grow freely, and to recommend things, like Privet, which are without beauty, and offensive in odour when in flower. The presence of such things is one of the causes of the miserable aspect of the shrubberies in many gardens, which might be very beautiful with varied life. The presence of many shrubs of little beauty often destroys by their vigour the rare and beautiful garden vegetation, so that we have not only the ugliness of a brake of Laurel, or Privet, or Pontic *Rhododendron* to survey, but often the fact that these things have overrun and killed far more precious things. And this nursery rubbish having eaten up every good thing begins to eat up itself, and hence we see so many shrubberies worn out. Lovers of the garden could do something to check this fatal tendency to monotony by taking up some family of plants for themselves which perhaps they are unable to find in the nursery gardens near. It is not only beautiful species of plants which are excluded from ordinary nurseries, but even special nurseries, as for Roses, will often exclude good things from their collections. It would be too much to expect that the enormous number of Roses grown should be grown by any one man, or even by any half-dozen growers; but the fact remains that even nurseries devoted to special subjects may be too exclusive. We say so much to show that even in the branches of gardening that seem best known there are neglected sources of interest, while among little-known plants there are many. But it is not only the introduction of new plants or species we have to think of here, but other things equally important: the raising of new forms (hybrids or varieties), the fine cultivation of interesting groups, as the beautiful forms of our native Primrose by Miss Jekyll; the making more artistic use of old and well-known plants; the skilful adaptation of plants and trees to the soil so as to get the highest beauty of which it is capable without excessive care or cost, and without the mourning and death that are visible in many places after hard winters. It is necessary to form true ideas of trade limitations, as many people seem to think that the nearest nurseryman possesses all the known art of gardening, and has all the plants worth having; whereas he probably is in a very narrow groove as regards either of those subjects. Therefore, those who seek to vary the monotony of gardens

must be prepared to face some little trouble, and not take the least notice of what is considered right in the neighbourhood, or what can be obtained from the nearest nursery garden, or even some of the larger nursery gardens. The further afield they look, probably the better in the end it will be for them if they would escape from the trammels of monotony. At the same time, if local men have good things they ought to be encouraged. It is a misfortune for gardens that there are not more local nurseries of an interesting character, because they would be the very best basis on which to see what local circumstances will best admit of.—*Field.*

## KITCHEN GARDEN.

### INSECT ENEMIES TO PEAS AND BEANS.

I THINK I may safely assert that all the leading seedsmen exercise very great care in examining all Peas and Beans before sending out to customers, carefully excluding any that may appear unsound or indicating insect attacks. Many small retailers of seeds ask gentlemen and their gardeners why they do not purchase from them, as they can supply equally as good seeds as the big houses and at a much lower rate. The latter may be true, but as to the seeds being equally as good is more than doubtful, which can be proved by comparison, and in the vast majority of instances it will be found that the cheap seeds have been a false economy. In the case of Peas and Beans this will be found especially true, by the introduction of insect pests into the garden. Of these amongst Peas, the Pea beetle (*Bruchus pisi*) and the striped Pea weevil (*Sitona lineatus*) are the worst. Peas infested with the beetle named can easily be detected through the holes made by the grubs, and should on no account be sown, but burnt at once, thereby minimising the danger of attack as much as possible. The striped Pea weevil is a much more serious enemy to combat and does more damage, as unless its ravages are checked, it will frequently destroy the plants. Some four years ago I had to contend against this foe, and could not imagine what was the matter with whole rows of Peas just staked, which, instead of growing well, appeared likely to vanish. On examining the under sides of the leaves I discovered the weevils in a fully developed state, and also larvae of the same, both feeding on the foliage and shoots day and night. Dusting with lime, soot, &c., had only a slight effect in preventing their ravages. What seemed to have the best result was repeated applications of liquid manure, and working into the soil with the Dutch hoe a light dressing of fish guano. It is possible that the manures were objectionable to the insects as well as stimulating to the Peas, but by one or both those causes fair crops were secured, although not so good as if no injury had been done by insect pests. Deep and thorough cultivation is also advisable to prevent further attacks, and even then it may take a year or two to eradicate it, even when the Peas are sown on fresh ground, as is usually done in most gardens. In my case it took two years to accomplish its extirpation.

The Bean weevil (*Bruchus granarius*) is evidently becoming more general, as out of various lots of Broad Beans obtained from several notable firms during the past few years every packet has had Beans therein infested. However, if all such Beans (which may be detected by the orifice) are burnt, only sowing

the sound ones, no unsightly breaks will occur in the rows through not putting in damaged seed. Last year our Broad Beans had a few strange caterpillars on them. On sending some to a well-known authority on such matters I was informed that they were the larvae of the gamma moth, and was strongly advised to carefully hand-pick the infested plants, otherwise they might increase to such an extent as to inflict serious damage to that kind of crop. In face of the many and apparently increasing quantity of insect foes that we have to fight against annually, it should be palpable to all that seeds should only be obtained from those firms who strive to send out clean stocks, that will not only be a credit to them, but also satisfactory to growers, by germinating freely and not prone to the enemies mentioned.

W. G. C.

**Radishes for forcing.**—These, if a proper selection be made, may be sown amongst Potatoes planted in frames. It sometimes happens when the old varieties of Turnip Radish are selected that they get smothered by the Potato haulm before reaching a size fit for use. This would not happen if one of the recognised forcing kinds were grown. Of these I find the Early Scarlet Forcing is the best, as the top growth is small and neat and the roots form very quickly. If a long kind is preferred, Wood's Early Frame will be found the best that can be grown, but for growing amongst other crops I certainly prefer the Turnip-shaped variety mentioned above.—J. C. TALLACK.

**Parisian Forcing Carrot.**—This is far ahead of any other kind of Carrot for sowing on hotbeds at this time of the year to get an early supply. Until I first grew this I used to depend on the old French Forcing for sowing at this time of the year and also for sowing in August in frames, but the Parisian Forcing comes in much more quickly. From a sowing made on February 7 last year we commenced pulling for use on May 1, and this from a hotbed only protected by spare lights being propped over it and without any side protection whatever. I prefer this plan to that of using frames, as the young plants are not then so liable to get drawn. They like warmth underneath, but do best when very little protection is used for the tops. I find that roots of these small kinds are more appreciated than those of larger kinds, and by sowing at intervals a supply is kept up the year round. The latest sowing is made in the pits used for Potato forcing, and the roots from this sowing, if lifted now and stored in sand, will keep plump and good till early sowings are fit for use.—J. C. TALLACK.

### EELWORMS ATTACKING TOMATOES.

EELWORMS are very difficult to combat with, but unless they are got rid of or kept under, the crops of Tomatoes are bound to be light. Preventive measures are most necessary in all cases where they have proved troublesome in previous years. If in the autumn F. Miles could have emptied his hot-water pipes and set the house wide open, he would have found gaslime the cheapest, safest and most effective remedy that could have been applied, and frosts also would have done good. Instead of going to the expense of removing the top spit of soil the border might have been double-dug, or, if the second spit is fairly good, completely trenched prior to receiving a dressing of gaslime, applied at the rate of half a hundred-weight to the square rod. For six weeks the gaslime ought to have remained on the surface, and be then forked into the ground. Why I do not advise using it now is because it is somewhat poisonous in a fresh state, and must be exposed long enough to get rid of some of its injurious properties. It might yet be tried, but at this late date a quarter of a hundredweight would be enough for a square rod of border, and after a week or ten days' exposure be forked in, planting

following in the course of another week, or longer if it can be delayed without unduly weakening the plants. Corrosive sublimate I have never used: it is a strong poison and said to dissolve the most readily in hot water. With this F. Miles might experiment on a small scale and note the results before running serious risks. Soluble phenyl I have used rather extensively with good results. This will be found a somewhat expensive remedy, especially if it is the roots and not the stem that is attacked. If the former are affected they soon become almost useless as far as supplying crude sap to the plant is concerned, and will be found on pulling up a flagging plant to be much clubbed or knotted. Before eelworms become established in the roots a thorough soaking of soluble phenyl should be given, and as this must only be diluted at the rate of one pint to eighteen or twenty gallons of water, it will be seen that a considerable quantity will be required for a large house. Another species of nematoid worm, or *Heterodera*, attacks the stem just below the surface, and are not so very long before they completely cut off all communication between the roots and the plant above ground, flagging being the first sign of attack. Once flagging commences there is no saving the plant, and it may as well be pulled up and burnt at once. In this case watering with the diluted phenyl close up to the stem so as to moisten all round the buried portion is a good preventive. It should be commenced before the plants set any fruit, and be repeated at intervals of about three weeks. If only a comparatively few plants are growing, I should advise baring the stems as deeply as can be done without damaging many roots, and well moistening with diluted phenyl prior to returning the soil on to the top of or up against the mess, the latter to be re-moistened with the phenyl occasionally. F. Miles can procure the phenyl through a local chemist, and should insist upon reduced rates being charged for large quantities if taken. Soluble phenyl is not prejudicial to the growth of Tomato plants, but rather the opposite. Chemical manures accompanied by abundance of water will also serve as a deterrent of eelworms, and it need hardly be added that a strong yet sturdy habit of growth is desirable in every way. W. I.

### NOTES ON LETTUCES.

ON page 80 "W. G. C." advises a limited assortment of well-tried Lettuces in preference to devoting time and space to those of doubtful merit. I can fully support him in his views. All the varieties named except Little Queen are well known and popular sorts, but I would venture to add one or two others which have done well with me after several trials. For forcing in frames and pits I prefer either Veitch's Golden Queen or Sutton's Commodore Nutt to the Early Paris Market for two reasons, namely, size and early maturity. Either of these two sorts matures more quickly than the Paris variety under the same conditions, and, being smaller growers, they can be sown or planted more closely together, which is a gain in frame culture. Beyond this I have not a word to say against Early Paris Market, as it is undoubtedly a very fine variety in every way, but its value is greater as an early outdoor and successional sort. I like to have some of the two first named for the sake of colour, one being green, and the other, as its name implies, of a golden tint. Both are equally good in quality and make firm little hearts, which, grown under glass, are so tender that they bruise if subjected to the least suspicion of rough treatment. For summer work Veitch's Perfect Gem is invaluable and without a rival, and where variety is needed, Neapolitan and Sutton's Favourite are capital kinds with distinctly crimped edges to their leaves. They are slow to run to seed, which is a consideration in summer. Stanstead Park grows to a good size and is a distinct Lettuce, but with me when first tried almost every one bolted, and I have discarded it. Daniels' Con-

tinuity and Marvel represent another section of Cabbage Lettuce, and where variety is desired they can both be strongly recommended for delicate flavour and long-standing qualities. Those who prefer a less crisp leaf than that furnished by Paris Cos or the selected Superb White Cos retained by all good houses should try Carter's Mammoth. This, as its name implies, assumes large dimensions, and also requires tying up to thoroughly blanch the heart and inside leaves, and this is the only drawback, I think, that can be attributed to it, particularly where labour is stinted. In texture it resembles to a large extent the Cabbage section, and this, coupled with its size, gives it a foremost place. It is a good market variety and stands hot weather well. Of winter Cabbage Lettuce there is none to excel the Hardy Hammersmith, and this has no value after the spring-sown plants are ready for use, and it is surprising how quickly they may be had at the foot of sunny walls from an indoor sowing, planting out as soon as strong enough to handle. From the same positions the Hammersmith can be cut throughout the winter, except in very severe weather, from August sowings. It is the hardiest and best in its section for winter work.

W. STRUGNELL.

## ORCHARD AND FRUIT GARDEN.

### GOOD COOKING APPLES.

ONE of the best cooking Apples is Lord Derby, which is illustrated, as this cooks and crops well, succeeding where others fail. It is a splendid town fruit, growing and cropping well under adverse conditions as to soil and climate. We have far too many varieties, the majority of poor quality; but the trouble is to select the best. The variety Lord Derby should certainly have a place. Amongst those Apples that will give a supply from September to May are the following. For early use it is well to plant such as Manks Codlin, a sure bearer and excellent as either a bush or pyramid. It is not a large grower and never fails to crop well, being fit for use very early in the season, cooking well and providing the table in advance of other kinds. For orchard culture as standards the well-known Keswick Codlin may always be relied upon, but it has a few faults, the greatest being it crops so freely, that many of the fruits are small. Where this is grown it is well to thin severely, and if only small trees are desired I would give the Manks preference. To follow this when cropping and other qualities are considered Lord Grosvenor is a very good selection, and in season from September to November. It is a large fruit of the Codlin type, a robust grower with large foliage, and a fine fruit either for market or private use. I have grown this variety when such kinds as Lord Suffield or Cellini failed, and, carefully handled when gathering, it may be had good up to Christmas. Cellini Pippin is a great favourite of mine in bush form, and I include it in my small selection, but it does not grow so freely in some soils as one could desire. In Gloucestershire and the surrounding counties it was our best all-round October fruit, its very handsome colour, acid flavour and free-cropping qualities making it a profitable variety and one that can be used for dessert if required. Of late years I have noticed a great tendency to canker with this variety, so that in planting it it is well to study the stock on which it is grafted, so as to get a clean growth, and in many soils I have seen it do better as a standard. In this form there is greater freedom of growth and less canker.

For mid-season or December use there are few better types of fruit than Lord Derby, and,

as shown in the illustration, it is a handsome fruit, large, angular, greenish-yellow, and of first-rate quality, a great bearer and a variety that rarely fails to crop; the tree is a strong grower and a splendid orchard variety. I have kept fruits well into the spring when given cool storage, but do not advise it for late use, but for mid-season supplies. New Hawthornden is a good variety for early winter use, and one of the best to crop in a young state and good in bush form. A large, handsome fruit of brisk flavour and a great favourite in the kitchen, this is also a good market fruit, and well repays good cultivation. Annie Elizabeth may be classed as one of the best varieties for gardens near towns or in poor soils; in standard form it crops grandly, and keeps sound well into March; indeed, by gathering late and giving cool storage, I have kept this variety for eight months. It is a large conical fruit, with firm flesh and first-rate quality. It has a brisk flavour and fruits regularly. I now come to a newer intro-

duction, I find a most reliable late fruit. This is in season well into May; the fruits are large, flat, dark green, firm, acid flavour, and streaked or flushed with bright red on the sunny side. This variety gathered late retains its good flavour to the last, and is a good cropper, grand as a bush or pyramid, and one well worth including in a select list. The well-known Dumelow's Seedling or Wellington does not thrive in all situations, but it has few equals as a late variety with me; it fruits freely enough, but the fruits are so spotted, that they soon decay, so that it is well to give it a limited space. Where it thrives it is a splendid cooker, good as a standard and much liked in the kitchen, and a heavy cropper when grown on the Paradise stock in a dwarf form. Those who do not select this may with advantage grow Newton Wonder, a valuable kind, in season in May, and much resembling the Wellington in keeping and cooking qualities. This latter is a new variety, but, so far, young trees have given very

*Fruiting branch of Lord Derby Apple. From a photograph sent by Mr. Norman Blake, Bedford.*

duction, and one noted as the best of its class, Lane's Prince Albert, and though it is now close upon forty years since this variety was first sent out, it is only of late years that it has found so much favour among all classes of growers. I do not know of any variety more profitable and a better cropper in any form; even two-year-old trees are so laden, that they have to be supported. The value of this fine variety was fully explained in these pages some few years ago, and since that date it is more popular than ever, and being a late handsome fruit with splendid cooking qualities, it is one that should be included in a limited collection and is in season during the spring months. As regards habit of growth it is somewhat pendulous, and with a heavy crop requires support. When grown in a bush form it should have space, and to prevent too free fruiting I have planted trees on the natural or Crab stock, which bear very fine fruits and are preferable to those on other stocks. Bramley's Seedling, another variety of recent introduc-

tion, Alfriston may be termed a late Lord Derby, as it is much like it as regards size, colour, and other good qualities. This is one of our best croppers, very large, late, and of acid flavour, firm flesh, and close, strong growth. With me it rarely fails, and we have trees in all forms and ages, our best fruit being secured from bush trees, and these latter rarely fail to fruit. There are others doubtless equally good as those named, but the above I consider most reliable when cropping and cooking qualities are considered.

G. WYTHES.

**Small Pears.**—The remarks of "W. G. C." (page 94) on small Pears of good flavour are not only interesting, but very useful, especially to those about to plant and whose knowledge of the merits of the different sorts is but limited. Guided entirely by trade lists, in which, unfortunately, the larger and more showy Pears and Apples are accorded the most praise, many are apt to fill their walls and gardens with inferior flavoured kinds, finding this out when too late. I

do not say it is necessary to plant many of these smaller kinds, as there are many of larger size of excellent flavour, but certainly where room can be spared, one or two trees of all the sorts named by "W. G. C." ought to be included. I cannot say much in favour of Citron des Carmes, as, although very early, it will hardly keep good twenty-four hours from trees on our soil. I find, however, a splendid substitute in Beurré Giffard, a Pear which "W. G. C." does not mention. This is very little behind Citron des Carmes in ripening, while it beats it out and out for keeping. It will crop well on Quince either as a wall tree or horizontal cordon. It has a somewhat musky flavour, which some might object to, but this is perceptible in many early Pears, notably Williams' Bon Chrétien. As a market Pear to be sold as soon as gathered, Beurré Giffard would, I think, answer well. I can endorse what "W. G. C." says in reference to Comte de Lamy. Very few Pears indeed possess a flavour superior to it. It likewise bears well in almost any form or position.—J. CRAWFORD.

**Mealy bug on Vines.**—Having read the remarks in your valuable paper respecting the above, it may be interesting to some of your readers to know the result of my experience in that respect. Having taken charge of the gardens at Bentley Priory, Stanmore, in 1896, I found a span-roofed range, principally vineries, in good condition, but with one exception—this being much infested with mealy bug—it was through no fault of the gardener who had charge of them before me, but the proprietor would have stove and greenhouse plants grown in them. I saw at once some severe measure must be taken. The houses were painted and the wire-work and walls well scalded, whilst 6 inches of the surface soil was taken away and made up with fresh; loose bark was also removed. I never was an advocate for scraping Vines, my impression having always been that it is injurious to them. I had boiling hot water poured over the Vines with a rose water-pot, and the Vines were syringed underneath in case any particle should escape the boiling water, the men having sufficient cloths to hold the syringe. They were afterwards dressed with a similar mixture as recommended on page 95. The second year about three bugs were found; the places were closely watched, but none appeared after in my time, and the vineries were much admired. I had experimented with the boiling water on scale before I commenced such an operation.—F. RUTLAND.

#### PLANTING AND MANAGING ORCHARDS.

THERE is still room for remarks on this subject, especially as spring planting is likely to be more general this season than usual. Personally, I am opposed to spring planting, preferring to carry it out in November while yet the ground retains some of the latent warmth of summer. New roots are then formed before actual winter sets in. This year, however, spring-planted trees are likely to do better, if in fairly sheltered situations and well cared for, than those planted in December, the roots of which have passed through an ordeal sufficiently severe to paralyse them, especially where the position is low and the soil retentive. In planting new orchards on pasture land there is often too much eagerness to get the trees in as soon as the ground is turned up; whereas if allowed to lie not only through the winter, but the following summer, being well hoed and scuffed at intervals to kill weeds and admit air and heat, the trees planted at the fall of the leaf will make more growth in one year than in three when planted in improperly prepared ground. With ground that is naturally fairly rich, ordinary trenching and at the same time working in plenty of good manure will suffice; but where the staple is either so shallow or so poor that holes have to be taken out and refilled with fresh compost,

more than ordinary provision ought to be made for the roots. When only one or two cartloads are placed in each hole it cannot reasonably be expected that fruit trees can thrive for long in such a limited larder. They never grow to half their normal size and the fruit produced is of the poorest. Six good cartloads to each tree is quite little enough, and when in a few years the roots traverse this the intervening spaces ought not to be allowed to remain Grass-covered, but be turned up a spit deep and annually dressed with good farmyard manure, that the strength may be washed down by repeated rains. We treat our Plums, Gooseberries and Currants in this way, and why not our orchards? Where Grass is allowed to grow it should be closely mown twice yearly and not grazed, as many fine young trees are completely ruined by cattle rubbing against the stems and eating the lower branches, especially when brought down by the weight of fruit. Indeed, for this reason some of our best cropping Apples, such as Lane's Prince Albert, cannot be planted where cattle have access on account of their weeping habit. I quite agree with Mr. Iggulden's statement some time ago that incalculable injury is done to fruit trees by the roots being exposed to harsh drying winds between lifting and replanting. I have frequently noticed trees offered for sale in country markets without a morsel of litter round the roots to protect them. Such trees are often purchased by farmers and others, and the roots subjected to further exposure, tied behind carriers' vans and other vehicles. Thus robbed of their vitality before being planted they linger on from year to year, a source of vexation to the owner. Another matter often overlooked in new orchards is shelter. This is of paramount importance, and where not afforded naturally may be supplied by planting single or, better still, double rows of well-furnished Larch on the exposed sides. These, though deciduous in winter, break into growth by the time the buds expand, and form a dense thicket before the blossom opens and the tender leaves unfold. Thinning out the shoots is also often carried to extremes, even in the case of old trees, in such uncertain springs as ours. Of late years I have noticed old, neglected orchards bearing crops of fruit, though small, while those receiving orthodox treatment in the way of liberal winter thinnings were minus fruit, owing to lack of shelter when the trees were in bloom. Last, but not least, comes the selection of varieties. Many err in this matter, even growers for market. As a rule, too many early and mid-season Apples are planted because they are known to be good croppers. Oldenburgs, Suffields, Grosvenors, and Ecklivilles are planted by the acre, with the result that the markets are glutted at a given time and prices rule low, as these sorts will not keep. What is really wanted is a good sized showy culinary Apple to precede the above sorts by several weeks, the same having a firm flesh and not liable to early decay. Of later sorts we have none too many. Lane's Prince Albert, Mère de Ménage, and Bramley's Seedling are all good, but I really think that some of our older varieties would still hold their own. The introduction of newer sorts has ousted them out of cultivation, at least so far as propagation is concerned, isolated old trees appearing here and there. For late use that most excellent variety Rymer was the sheet anchor of the old school, keeping sound and firm into May, and needing very little sugar when cooked. It was a heavy and certain cropper and resisted frost well. Hambleton (deux Ans, another old Apple, is well worth extended cultivation on account of its long-keeping properties and fine flavour. It

will grow to a good size on good soil. Sturmer Pippin is a most useful late Apple, being very acceptable in the dessert during April and May, and unsurpassed at that date for puddings and pies. It makes a fine symmetrical tree, sets a crop under adverse climatic influences, but requires good soil, so that the fruit may attain to its full size, otherwise it is liable to shrivel at the turn of the year. J. CRAWFORD.

#### SOCIETIES AND EXHIBITIONS.

##### NATIONAL CHRYSANTHEMUM SOCIETY. ANNUAL MEETING.

ON Monday evening last the annual meeting of the members of this society was held at Anderton's Hotel, Fleet Street, the chair being occupied by Mr. C. E. Shea.

After the secretary had read the notice convening the meeting, the minutes of the last general meeting and the minutes of the special general meeting in May last were read and confirmed. It was, as will be remembered, at the latter meeting at which Mr. Jukes was presented with an illuminated address on his retirement as vice-chairman and the discussion on Mr. Shea's paper on judging took place.

The annual report for 1894 was then presented, from which we learn that large additions to the roll of membership were made and that nineteen new societies were admitted in affiliation. The society's own shows fully maintained their reputation as the best in London, and the one held during November was considered to be the largest in the United Kingdom. The contest for the challenge shield brought forward five competing local societies, and resulted in a win for the Bromley Chrysanthemum Society. The meetings of the floral committee had been the means of bringing forward a large number of new varieties of great merit, and it is probable that during the months of October and November these meetings will in future be held at more frequent intervals. Reference was also made to the retirement of Mr. E. C. Jukes and to the presentation of an illuminated address recording the society's thanks for the valuable services that gentleman had rendered as an officer of the society. It was also pointed out that the work of the N.C.S. had embraced the issuing of a new supplementary catalogue and the Chrysanthemum Year-Book recently published. The president, Sir E. Saunders, still continues his warm interest in the society's welfare, and the report concluded with an expression of the greatest regret that the committee had learned the resolve of Mr. R. Ballantine to retire from the position of chairman of the general committee. Appointed vice-president in 1879, he became chairman on the retirement of the late Mr. E. Sanderson, a post he has filled with great credit to himself and advantage to the society. There is, however, reason to hope Mr. Ballantine's exertions in promoting the best interests of the society may be continued as a member of the general committee.

From the financial statement it appears that there were between six and seven hundred members in 1894 whose subscriptions amounted to £246 1s. 9d. Donations were received to the extent of £41 15s. 6d. Royal Aquarium Society contributed £294 16s. 6d.; affiliated societies' fees and receipts for medals supplied them was £143 —, and other sources of revenue bring up the total for the past year to £847 0s. 5d. The largest sum on the expenditure side is for prize money at the society's shows in September, October, November, and December, and, with the value of the medals awarded, amount to £426 3s. 1d.—the remaining items being of the usual kind, varying in amount. A balance of £29 10s. 2d. remains to the society's credit.

The chairman, in proposing the adoption of the report and balance-sheet, thought that in these days of depression the report and increased

financial balance were evidence of the prosperity of the society, especially as the past year was an ordinary working year of the society, and not an exceptional one like the centenary year. It was resolved that they be adopted and printed for circulation in the usual manner.

The election of officers was then proceeded with, with the following results: President, Sir Edwin Saunders; treasurer, Mr. J. R. Starling; chairman of committee, Mr. B. Wynne; vice-chairman of committee, Mr. T. W. Sanders; hon. secretary, Mr. Richard Dean; foreign corresponding secretary, Mr. C. Harman Payne.

One-third of the general committee retiring by rule, but being eligible for re-election, resulted in some fresh nominations being made, and there were five new members elected.

The business of alterations to the rules then occupied some attention, but the reader must refer to the new schedule, which is already in the printer's hands, for details. The following gentlemen were elected vice-presidents: Mr. Coles Child, president of the Bromley Chrysanthemum Society, and Mr. R. Ballantine.

The Woolwich Chrysanthemum Society was admitted in affiliation.

On the motion of the secretary, a vote of thanks to the chairman was passed for his able management of the meeting.

#### Scottish Pansy and Viola Association.

—This association has been formed in Glasgow to meet monthly during the summer to consider new varieties of Pansies and Violas, and to award certificates to them if deemed worthy. The following seven gentlemen have been appointed judges: Mr. J. Baxter, Daldowie; Mr. Wm. Cuthbertson, Rothesay; Mr. M. Gray, Glasgow; Mr. M. Campbell, Blantyre; Mr. J. Stewart, Lennoxton; Mr. W. Maxwell, Glasgow; Mr. H. Hamilton, Lochwinnoch. The judges are to give their verdicts by ballot. Varieties which receive three-fourths of the total number of points shall receive a first-class certificate, and those receiving one-half or more of the total number a certificate of merit. Another special feature will be the granting of special certificates for constancy to varieties which obtain a first-class certificate at three meetings. Such certificates and decisions it is hoped will prove valuable guides to the public and tend to set up a standard for new varieties. The membership of the new association is open to all on the payment of a nominal subscription of 1s., and provision is made for the reception of flowers by post, which shall be as carefully handled and adjudicated as if they were personally staged by the exhibitors. The following are the office-bearers, any of whom will be glad to send a copy of constitution and rules of the new association to interested parties: President, Mr. Wm. Cuthbertson, Springfield, Rothesay; vice-president, Mr. John Baxter, Daldowie; treasurer, Mr. Jas. Robertson, Turnerfield, Crow Road, Partick; secretary, Mr. John Smellie, Pansy Gardens, Busby.

**The weather in West Herts.**—The weather during the past week has been less cold than in any week since the third week in January, and at no time did the exposed thermometer show more than 13° of frost. The ground still continues very cold. At 2 feet deep the temperature is only half a degree above the lowest reading recorded during the frost, and at 1 foot deep has as yet risen only to the freezing point, which is 2° higher than when at its lowest. February was extremely cold. On two days (23rd and 24th) the highest day temperatures just touched the average maximum reading for the month, and on three nights the lowest night temperatures were also about average. Otherwise the weather remained cold throughout. Snow fell on three days and rain on one day, so that the total rainfall for the month comes out remarkably small—amounting only to two-tenths of an inch, or nearly 2 inches in defect of the February average. Dry as this month was, there has been another February still drier during

the last forty years, viz., February, 1891. For altogether 456 hours, or nineteen days, the direction of the wind was some point between north and east. The record of bright sunshine was rather above the average for February. The recent frost may be said to have lasted from January 21 to February 21, or for thirty-two days without a break. That is to say, on no night during that period did the thermometer in the screen fail to register a temperature below the freezing point. The double Snowdrop was first in flower in my garden on February 26, or seventeen days later than its average date of flowering in the previous eight years, and thirty-six days later than last year.—E. M., *Berkhamsted*.

### NOTES OF THE WEEK.

**Flowers from Ireland.**—We have received from Mr. T. Smith, Daisy Hill Nursery, Newry, a gathering of early spring flowers, amongst them *Iris reticulata*, *I. histrioides*, *Crocus Imperati*, *Galanthus nivalis pallidus*, the handsome *G. easaba*, and a bunch of the pretty *Cyclamen eoum*. The foliage of *Tellima grandiflora rubra* is very fine for colour. Sent with these are *Veronica selaginoides*, the green colouring quite pleasing, forms of *Erica*, *E. tetralix mollis* and *E. carnea*, *Andromeda Catesbii*, whose leafage is of a rich crimson tint, several shoots of *Andromeda*, and *Cassinia fulvida*—quite an interesting gathering of fine-leaved things and early flowers.

**Notes from Derbyshire.**—February 23. Snowdrops in the woods peeping through their snow blanket, and the bright yellow Aconite. Gathered a few of each just one month later than 1894. A late sown lot of Dobbie's White Turnip are very acceptable from the open ground; a dish cooked and served up whole proved excellent. Brussels Sprouts, greens, &c., are very good. Beds of Carnations, rather pressed down with the weight of snow, are freshening up, and look none the worse for their two months' covering. Daffodils, *Gladiolus The Bride*, and other early sorts, Tulips, &c., plunged in cold pits with cocoa-nut fibre, in spite of their being long frozen, are looking well.—GEORGE BOLAS, *North Derbyshire*.

**Azalea linearifolia.**—This curious species differs from all other Azaleas in almost every character but that of floral structure. It forms a flat-headed bush 3 feet to 4 feet high, each branch being terminated by a tuft of narrow light green leaves, which are densely covered with hairs. The specific name is very appropriate, as the leaves, which vary from 1½ inches to 3 inches in length, are not more than one-eighth of an inch wide at the broadest part, and taper to a point. The flower is composed of five narrow petals, similar in shape to the leaves, each one being 1½ inches long and of a light rosy purple. This Azalea, which is a native of Japan, will grow out of doors if planted in sandy peat and given a moist and sheltered position. In the cool greenhouse it grows well, and during February and March produces its flowers in abundance. Except for those, however, who like to have curious as well as beautiful plants in their greenhouses, it is scarcely showy enough to gain an entry there, but outside it makes an interesting and pretty bush, and is certainly worth cultivation.

**Tremandra Hugeli.**—This is a dwarf, bushy plant, usually not more than 1 foot in height, with numerous narrow and pointed leaves not more than half an inch long, and covered with short hairs. The flowers are produced from the axils of the leaves near the point of each shoot. They are nodding, upwards of 1 inch across if fully spread out, and of a pale, but bright purple colour. The petals are four in number, obovate, and, on account of their opening to only about half the full extent, render the flower somewhat campanulate. At present this plant does not appear to be very well known, although considerable quantities have during the last few years been grown in one at least of the large London

nurseries. It is just now coming into bloom, and its bright flowers and neat compact habit make it one of the prettiest of small greenhouse plants. Unlike the majority of its fellows in the *Tremandra* family, it is very easily grown and propagated. Its requirements are the same as for soft-wooded Heaths, to many of which it bears a close resemblance in habit and foliage.

**Spring flowers.**—We have now had three mild days, and the ground is thawed to the depth of about 2 inches, but in the face of the frozen conditions below, where nearly all bulbs and roots must be ice-bound, the progress made by many things is quite marvellous. I had a quiet walk round to-day (Feb. 23) and found the following: Winter Aconites everywhere, both in shade and sunshine, in full flower, many kinds of Snowdrop, *Colchicum fasciculatum* with numerous small rosy flowers—in fact quite a rosy patch. This does not appear to have suffered in the least either in leaf or bud; it is a pretty little species. *Cyclamen eoum*: about a dozen square yards of this in a sunny aspect has really thousands of flowers—in fact there is quite a red glow, very good indeed; while the same plant in shade has not an open flower. *C. alpinum*, a charming thing, has also a few open flowers. This is near to *eoum*, but the leaves are only about one-third the size. *Polygala Chamæbuxus* and *P. C. purpurea*, whose buds simply held in reserve during the cold, are already glowing with yellow or purple, as the case may be. *Crocus gargaricus* has dozens of pretty little intense orange-coloured flowers, and a few are nearly red in their intensity. These, I think, were injured by the cold in the bud state with this result. *C. vitellinus* has also dozens of open flowers, but of a much paler yellow. *C. Sieberi*, *hyemalis*, *Imperati*, and *Fleischeri* have also plenty of buds and some open flowers. *Muscari azurea robusta* is already blue. *Narcissus cyclamineus* is just showing the yellow, and will be our first Daffodil. I believe all the early scapes of *N. pallidus precox* are killed. *Pulmonaria saccharata* is showing its ruby buds. *Sisyrinchium grandiflorum*, about which we annually write, is prostrate (it was very forward, with many flowers open before the frost set in), having been killed at the snow line. An instance of excessive hardness is found in *Fritillaria liliacea*, whose young growths are from 2 inches to 3 inches high and quite unharmed. In a garden fairly stocked with hardy plants there is really no part of the year without interest, and the above is no mean record at this date.—T. SMITH, *Newry*.

**Opening of Lincoln's Inn Fields.**—These gardens were recently opened by Sir John Hutton, chairman of the London County Council, for the public.

**Cattleya Lemoniana.**—Can you give me any information as to what Feat. &c., is required for *Cattleya Lemoniana*, as I have a plant labelled by this name, and it never flowers, although it grows freely? Any information would greatly oblige.—J. J., *Newport*.

**Supporting Hyacinth spikes.**—Would "J. C.," who recommends wire for this purpose, kindly explain what kind and size he advises? If he has not wire game at hand, perhaps he could give the diameter in centimetres, or in thirty-seconds of an inch. Probably galvanised wire need be only half the diameter of copper wire to secure the same stiffness.—W. T. B.

**Names of plants.**—*H. Greenwood*.—*Dendrobium nobile*, a very highly coloured form, but not *nobilis*, which has much darker and larger flowers.—*Mrs. Stephen Marshall*.—*Amaryllis sulcata*.—*T. G. Binney*.—Not *Dendrobium nobile nobiliss*, but a very good form. It is not particularly valuable, because of late years we have received such splendid varieties of this *Dendrobium*.

**The Wild Garden: or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers.** Fourth edition, with wood engravings from drawings by Alfred Parsons, revised and enlarged. Lemay & Co., linen cloth. Price 12s.; well bound in half morocco, 18s. Through all booksellers.

"This is an Art  
Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ROSE GARDEN.

### ROSES UNDER GLASS.

MORE than once have I been asked whether Roses under glass are better in or out of pots, and, from a look round among my own recently, the thought occurred that a few words upon this matter might be of some service to inexperienced growers. Whether they are better in pots or not must depend to a great extent upon two things—what they are wanted for and the space at disposal. The variety to be grown also has some considerable bearing upon the matter. We cannot cover a roof with *Maréchal Niel* or any other strong climber from an ordinary pot plant. So great a quantity of growth naturally requires a corresponding amount of suitable soil. A box or half of a tub may serve our purpose, but a pot will not. Such kinds as *The Bride*, *Niphetos*, *Sunset* and *Comtesse de Nadaillac* seem best in pots, as we can then remove them as they go out of flower; nor do these and similar varieties make sufficient wood as a general rule to pay for turning out. Putting the selection of varieties on one side, there is the question of more uniform moisture and unconfined root-run. A border of *Teas* in a house 10 feet high was planted in 1885, and is still a success. For steady forcing these do very well, but on the walls of the same house *Roses* are apt to feel the effects of cold soil from the outside, and it is very certain that many of their roots have rambled beyond the inside soil during those years. Our soil must be entirely inside and the roots kept to this if we are to force *Roses* that are turned out during such cold weather as we generally have through January and February. It is obviously unreasonable to force specimens of climbing or other *Roses* while many of the roots are in cold soil, and for this reason I would advise that all hard forced plants be grown in pots, so that the soil may also be warm. Let them be partially plunged if on a dry bench, and they are better so when growing on a side border. We do not find the soil outside in summer so hot as the atmosphere, and if we allow our soil to get too warm and dry, there is danger in that direction as well as in the other extreme. When turned out into a larger mass of soil the roots can secure more uniform moisture, and are seldom checked and crippled by sudden drought. Under good management this should not occur with pot plants, but still it does occasionally happen that a few get neglected and lay the seeds of many ills among the whole batch. Mildew, for example, can often be traced to this cause as well as draughts and unreasonable ventilation. Insects of all kinds seem to thrive more upon plants that have received a check. Doubtless much of the latter is fancy, seeing that our plants would naturally be making less progress even if not affected by insect pests; but in the case of mildew, I take it to be an established fact that this disease spreads more rapidly when a plant is out of health. The unhealthy growth and mildew accompany one another, although we frequently see a wonderfully thriving batch of plants suddenly attacked in a most alarming manner and quickly ruined; but the primary cause was a chill or check of some kind.

I would rather have to look after *Roses* turned out into a border of soil that was all under cover than a batch of pot plants, and it seems to me to be more in keeping with Nature that the soil should receive warmth from the surface rather than from all quarters, as is the case when a pot plant is stood on a bench. *Roses* in the former state are longer lived, break more evenly and strongly, and grow away more naturally. But, as I have already pointed out, much depends upon the variety and section of *Rose* cultivated. The *Fairy* or *Lawrenceana* section, for example, are far more serviceable when grown in pots, while the strongest growers of *Teas* and *Noisettes* can scarcely derive sufficient and continuous support when limited to a pot to do themselves justice either in growth or bloom.

RIDGEWOOD.

### DARK ROSES IN POTS.

SWEET and charmingly delicate as are our *Tea* and *Noisette* *Roses* when grown under glass for winter and early spring blooming, we cannot get the dark and glowing crimson with maroon shadings found only among the *Hybrid Perpetuals*. A good red *Rose* in winter has a wonderful charm either by itself or when brought into contrast with the more delicate shaded *Teas*. Their perfume, too, is so distinct from others, that both for this and colour they should be grown more often. Granted that the *Teas* are more free-blooming and a little easier to manage, with more care in starting our *Hybrid Perpetuals* steadily we may have them in good form. Selection of varieties has considerable bearing on this, and such as *Horace Vernet*, with other bad growers, although occasionally producing a truly magnificent bloom, are quite useless for winter work under glass. Having proved this, I will name half a dozen dark *Hybrid Perpetuals* that are most suited for our purpose, and then proceed to give a brief outline of their culture.

*GENERAL JACQUEMINOT* is a deep red with dark shadings, particularly free both in bloom and growth, also exquisitely scented.

*FISHER HOLMES* is a sturdy and uniform grower with dark scarlet and maroon shaded flowers. Like the above, every bud or bloom is useful and good.

*A. K. WILLIAMS* does well under glass, and affords an intense carmine-red with magenta shadings.

*GUSTAVE PICANEAU* is a bright shaded carmine, very large—in fact, one of the largest—a moderate grower and thoroughly continuous in blooming.

*PRINCE CAMILLE DE ROMAN* will give us a deep maroon and velvety crimson, almost black at times; while if we want a red climber we must go to *Reine Marie Henriette*.

Now for a word upon their culture. Let them be established in pots previous to housing. The best plan is to pot up one season and force the next, putting them well plunged in a pit during the first summer. Any good rich soil will do. I like to use a fair sized pot, say one of 8 inches, and leave 2 inches or more of surface space. This guards against drought at the roots while outside during the first summer, as more water is accommodated at a time. It also leaves us room for an efficient mulching before forcing the following season, and we are able to cover the base of our plant more effectively. The value of this will be seen as the season advances, for it is essential that the eyes around the base should be encouraged to break strongly, and not only supply late flowers, but produce valuable wood for the third season.

Now about pruning. Do not study this too much, but cut out spray-like wood first, and then

fix any very healthy and stout shoot in as horizontal a manner as you can. Much depends, too, upon the size of your plant and pot. As the young growth advances the shoots can easily be tied out to short sticks, somewhat in the same way as fancy and show *Pelargoniums*. It is fatal to hurry a *H. Perpetual Rose*, especially at the first. When the buds can be discerned in the new growth we may afford more heat, and now is the best time also for weak liquid manures. Any kind will do; indeed, it is advantageous to change, but be sure it is weak and freely supplied in preference to stronger and rarer doses. The ordinary culture for *Roses* under glass, and which has been so often given in these pages, will suit very well beyond this. It is a question of varieties and steady treatment. R.

## KITCHEN GARDEN.

### DIFFICULTIES WITH ONIONS.

LATTERLY I have spent much time among amateur gardeners, this including cottagers, and have made it part of my business to find out what they most often fail with. That there are plenty failures, partial or otherwise, need hardly be stated, but as yet it is *Onions* that seem to baffle my friends the most, and I get more inquiries about these than upon any other class of vegetables. To the ravages of the *Onion maggot* must be attributed most failures, but mildew also has to be reckoned with in some districts, while I also found out that some of the least experienced growers were under the impression that *Onions* could be grown on poor ground without manure. So they can if only wanted for pickling. In all probability, however, if the ground was well prepared for *Onions* and more liberal treatment accorded generally, there would be far fewer complaints of failure from any cause. If grown quickly and strongly the *Onion maggot* would have less time to work destruction, as they are almost powerless against strong or nearly fully grown plants, and the mildew is also most destructive among backward plants. Chemical manures and soot, in addition to stimulating a rapid growth of plant, are also obnoxious to insects generally, and a free use of soot alone has been the means of saving many crops. Cottagers, in particular, fail to realise what a valuable manure, insecticide, and disinfectant they have in soot. If they do employ a chimney-sweep they allow the latter to carry away the soot, while in very many cases the chimneys are never swept, but, in defiance of all laws, are burnt out as often as need be. Soot can usually be brought at the rate of 8d. per bushel, and one peck of it is enough to dress a square rod of ground. This should be forked lightly into the surface prior to sowing the seed, and those who mean having a full crop of fine *Onions* would only regard the soot as supplementary, good solid manure being previously dug in at the rate of three barrow-loads to the square rod. When I had to contend with the *Onion maggot*, common salt was used at the same time as the soot at the rate of 4 lb. to the square rod, while road grit was also liberally distributed over the ground and then lightly forked in. Salt, however, is not suitable for clayey soils, as it first causes them to run badly when it is wet, and then crack seriously in dry weather, road grit being also of most service in solidifying lighter soils. As it happens, it is the lighter soils that are most infested by the *Onion fly* and its progeny, those that set well, that is to say run together rather on the surface, offering fewer facilities for the movements of the fly and maggots. In bad cases a second dressing of soot at half the previous rate should be given when the rows of plants are well defined, and this be lightly stirred in with a Dutch hoe. For light soils, half as much as previously used of salt may be added to the soot, or, better still, nitrate of soda be used instead at the rate of 1 lb. per square yard, sowing along the lines of plants

and between them rather than recklessly broadcast. For heavier soils, sulphate of ammonia in a well pulverised state may be substituted for the nitrate. It will be seen that I do not favour broadcast sowing, distributing the seed very thinly along shallow drills drawn from 10 inches to 12 inches apart being the most economical and the best in every way. Having to thin heavily is always unfortunate, as it is very prejudicial to those that are left and also seems to favour the increase of Onion maggots. Always thin early, or as soon as the plants can be drawn, but if they are not more than 3 inches apart, leave the lot, and if a little thicker than that, it will not much matter unless extra fine roots are desired. It is the bunches of plants that I object to.

Growers of exhibition Onions are not nearly so much troubled by the Onion maggot as are those who take less pains with their crops. In their case success is due not merely to the extra preparation of the ground in the shape of free manuring and deep digging, but they also adopt the practice of raising all the plants they require under glass, sowing the seeds in heat early in February. Several hundred plants can be raised in a single box, and these, when about 4 inches high and after being duly hardened off, should be planted out from 4 inches to 6 inches apart in lines 12 inches apart. They would be well ahead of any obtained by sowing in the open ground late in February or early in March, and more than maintain their lead. These early-raised, transplanted Onions not only attain a great size, but they are usually of perfect form, mature early, and keep well accordingly. The most successful cultivators grow the new large varieties to an enormous size, so much so, that they are sometimes mistaken for imported Onions. Ailsa Craig when weighing from 3 lbs. to 5 lbs., as they frequently do, most resemble Portuguese Onions, being of much the same shape as those imported. Sandy Prize and Anglo-White Spanish also grow to a great size, but are of more perfect form. When seeds of these rather expensive varieties are sown in heat, all or nearly all germinate, and every plant is saved. Sown in the open, there are almost certain to be some losses, and that is another point in favour of sowing in boxes and transplanting. The Onion maggot is bad enough to contend with, but in some gardens mildew is even more to be feared. A change of site and good culture are to a certain extent preventives of the former, but with mildew a change of site is apparently of no avail, and once it starts it is liable to over-run a large bed in a few hours, the wind assisting to spread the disease. Some growers are of opinion that it is analogous to one of the diseases that sometimes over-run Potatoes, and that it is unwise to locate the Onion bed near to Potatoes. Authorities are quite of opinion there is no remedy for mildew in Onions once it is firmly established, and all measures taken should, therefore, be of a preventive nature. A very successful grower of my acquaintance who is practising gardening in a district where the disease works sad havoc among the Onions is not troubled with it in the least, and attributes his immunity to the rough-and-ready method he has of drenching the rows with soap suds, sewage water, liquid manure or anything else he can get of a somewhat similar nature, very frequently during the early part of the summer. This causes the Onions to grow so robust as to practically render them mildew-proof. Others find a mixture of newly-slaked lime, soot, and flowers of sulphur efficacious, only it has to be applied daily in wet weather, owing to its failing to stick. Spraying with Bordeaux mixture, a remedy for Potato disease, is also worthy of a trial on Onion beds, only unfortunately this is not well within the reach of cottagers and most amateurs. As an horticultural instructor, it will be part of my duty to try this remedy, and as I propose using it in various centres, something definite as well as instructive should be arrived at. A ROVER.

**Notes on Lettuce.**—"W. G. C.'s" selection of Lettices (p. 80) is a reliable and comprhen-

sive one, but I venture to add two Cabbage varieties, viz., Golden Queen and New York, the former for forcing and early use excelling Paris Green, and the latter superior to any kind I have grown for summer, but, nevertheless, a variety that seems little known. I am aware these are strong assertions, but I hope "W. G. C." will give both a trial; if he does, I feel certain he will confirm my opinion.—J. R.

**Two good Celeries.**—Celery Leicester Red undoubtedly deserves the word of praise "J. C." (p. 80) accords it, for it possesses all the good qualities ascribed to it, and should be largely grown for main crop. Carter's Incomparable Crimson is excellent in every way for the latest crop, unsurpassed for crispness and nutty flavour, and the latest in "running" of any variety I am acquainted with. If it has a fault at all it is its extreme brittleness, requiring the utmost care in handling to prevent the sticks from being broken. I unhesitatingly recommend it as a sterling late variety.—J. R., *Merioneth*.

**Early Carrots.**—A good deal has been written of late respecting Carrots and the earliness of certain varieties. I have previously written in praise of the new variety Market Favourite, and would urge all those who grow them in frames or on early borders to give it a trial. I used to think the old Nantes Horn would never be beaten for speed, but grown under exactly the same conditions either in frames or in the open, Market Favourite is ready for drawing a fortnight earlier. It is certainly not so deep in colour, but where earliness is a consideration this is not of such importance. It is of good length and thickness, very symmetrical, and without much core. Having rather a large top, it requires plenty of room.—J. CRAWFORD.

**Sowing Early Parsnips.**—Many growers of Parsnips will be anxious about the state of the soil, as we are told that the sooner the seed is in the ground the better, but I fail to see why such should be the case. I do not grow for show, as we do not want roots a yard long, in fact have no means of cooking them. Medium-sized roots are of better flavour than large ones, as when seed is sown early in April, that is along with the main crop of Carrots, roots 18 inches long with a good thickness can be secured by autumn. As regards variety, I think the Student superior to the Hollow Crowned. It is of good flavour, and being a medium-sized root is certainly the best variety for private gardens. For keeping till late in the spring I often sow a little seed in the end of April or early in May, and do not lift, but leave in the soil. The roots are valuable, and, being tender, much liked in the kitchen.—S. M.

**Late Purple Sprouting Broccoli.**—The plants sown the first week in May have passed through the very severe weather we have experienced without injury, whereas the earlier kinds sown in March are killed to the ground. I am aware the late kind is not so nice looking as the white, though this latter is advised in seed catalogues to be sown for use in April; but in such seasons as we have experienced I fear there are few white kinds left, unless much sheltered. Even the Early Purple form is much injured. The Late Purple is a tall, large grower when sown too early or crowded in its earlier stages, and, as is well known, such plants suffer most; hence the necessity of growing compact plants and as firm as possible. This kind is certainly much hardier than any other and of good quality when cooked. It is one of the first vegetables to start into growth after severe frost, giving a lot of material for weeks when green vegetables are valuable. To get a long succession plant in different positions. If a north border can be spared the supply is much later, and in all cases I have found that the Kales give the best results when grown as hardy as possible. S. H. B.

**Tuberous Artichokes.**—Accepting the tuberous-rooted Stachys as an Artichoke, we have made during the past few years at least a couple of notable additions to this hardy, but by no means popular section of edible roots. The first,

though latest, is the white Artichoke of the Helianthus family, the other being the Stachys or Chinese Artichoke. Everyone now admits that the White Jerusalem variety is much superior to the old brown-tubered form in shape and in flavour, as well as quality of flesh. Some gardeners even go so far as to say that there is in respect of flesh quality no comparison between the two, but we all know what great differences are found in diverse methods of cooking. Still, without being more prolific, the white form is undoubtedly a considerable improvement. Jerusalem Artichokes should be, like Parsnips, cooked in very little water, so as to have the flesh melted rather than boiled; also they should be served, whether whole or mashed, as dry as well can be. The Stachys tuberifera evidently owes much of its popularity, or lack of it, to cooking. That the tubers are easily grown is evident, and the plea that once in the ground it is hard to destroy seems out of place, as where trouble is given the year following the growth of a crop, a free use of the hoe on the top would soon destroy them. The roots are best left in the ground all the winter, but a portion of a bed should be covered up with litter, so as to enable access to be obtained. When lifted, the roots should be thrown into water to exclude air and preserve whiteness, then gently boiled, and later drained dry, then fried in butter, some being partly browned, and then served with sauce or gravy. So treated, they constitute a most delicious dish, one that thousands would like to have often during the winter months.—A. D.

**Winnigstadt Cabbage.**—Although I have grown this excellent Cabbage extensively for many years, I have happily not found the difficulty "G. W." mentions (page 40) of getting the true stock. It is a splendid autumn and winter variety for supplying the demand during those seasons. The quality is exceptional, and it does remarkably well on light soils.—J. R.

**Lee's Cabbage Lettuce.**—For the winter and coming in early for use in the spring this Cabbage Lettuce can be highly recommended. During April and May excellent heads of much crispness are obtained from autumn sowings upon warm south borders.—J. R.

**Early Potatoes.**—Without doubt it repays any gardener well to incur the trouble and expense incidental to erecting a light temporary framework or trellis over a warm border after having planted the ground somewhat closely with dwarf early Potatoes. If the sets have been first sprouted in gentle warmth and in full light, then disbudded to one, or at the most two sprouts, they are in the best possible condition for planting. The border should have worked in during the planting some half-heated short manure and leaves, as through that agency growth is stimulated. If such plantings be made about the middle of February, tops are well through the ground in three weeks, and over the trellis or framework erected there should be drawn at night a stout canvas cover, or have mats thrown over to preserve warmth in the soil, and later to protect the tender tops from frost. If the sets have been planted 6 inches in depth and in rows 15 inches apart, earthing will be impossible, and indeed not required. In such a way it will be easy to have fine young Potatoes several weeks before they can be dug from unprotected borders. A few sorts specially suitable for this form of culture are Ringleader, Laxton's Early, Sutton's A1, Veitch's Ashleaf, Sharpe's Victor, Midsummer Kidney, all good, having shortish tops and precocious croppers. We have not given so much attention to the first early section of Potatoes as to later ones, but there can be no doubt that the production of any variety that shows in the direction of short tops and exceptionally early tuber special excellence is indeed a great gain. The growth of some of these sorts in pots in early vineries, Peach houses, or in frames always repays, though in that case the tuber production is relatively much below that of open-air plantings.—A. D.

**CHRYSANTHEMUMS.**

**ANEMONE-FLOWERED CHRYSANTHEMUMS.**

IN THE GARDEN for November 24 last I took the opportunity (p. 440) of drawing attention to some of the most attractive forms of this section which had then just recently been staged at the National Chrysanthemum Society's exhibition at the Aquarium. Anemone Chrysanthemums have been so long and so steadily

that the disc be high, certainly not less in form than half a globe; at the most but a trifle more than that."

Of the varieties that were generally in cultivation fifteen years ago when I first took up the cultivation of the flower, Acquisition, Bijou, Fleur de Marie, Glück, Georges Sand, King of Anemones, Louis Bonamy, Lady Margaret, Mme. Goderau, Mrs. Pethers, and Prince of Anemones were, perhaps, some of the most popular, and belong to a distinct type. In later years these old sorts seem to have been employed by the seedling raisers of France and

the latest of the new type. Looked at as a Japanese or hybrid Anemone, as they were first called, it is probably one of the best, and likely as an exhibition or a decorative flower to be of some value. It is a seedling of English origin, having been raised by Mr. H. J. Jones, of Lewisham, in 1893 and distributed by him in the spring of last year. It was flowered in the Rye-croft Nursery last autumn with considerable success, and was a rather bold, striking-looking variety of its kind, although, to my taste, less charming than the new French seedling Junon, on view there at the same time. On November 21 the flower bearing the distinguished novelist's name was submitted to the floral committee, and from my notes of that meeting the following description is extracted: Very long guard florets of medium width, good centre, tubes rather loose, deeply toothed and open at tips, colour pinkish white, centre deep rose, shaded yellow, very large blooms.

Some of the newer forms of the Japanese Anemone section will no doubt find admirers among the flower-loving community of the present generation, but the old school florists are firmly wedded to their idea of "properties," and to these the Japanese Anemone does not conform.

Probably the first of the group was Duchess of Edinburgh, introduced by Messrs. Veitch and Sons in 1875, and this remained for some years the only variety of the kind. Some few years later Fabian de Mediana, Mme. Berthe Pigny, Mme. Clos, Mme. Thérèse Clos, Mlle. Cabrol, Marguerite Villageoise, Sœur Dorothee Souillé, Souvenir de Lardenne and Timbale d'Argent followed, and were pretty generally grown and shown, but these are now giving way to other introductions of the same kind. The great fault of the Japanese Anemone Chrysanthemum is its tendency to run to lilac or mauve shades of colour. Good crimson and yellows would undoubtedly be a distinct gain, and in the latter the best example at present is John Bunyan. C. HARMAN-PAYNE.

*New Japanese Anemone Chrysanthemum, Rider Haggard. From a photograph sent by Mr. H. J. Jones, Rye-croft Nursery, Lewisham.*

**CHRYSANTHEMUM W. H. LINCOLN.**

I AM at a loss to understand how Mr. J. C. Tallack (p. 128) arrives at the conclusion that my note on the above Chrysanthemum (p. 104) bears out his contention (p. 58) that, when growing this variety for the production of cut blooms, disbudding is an absolute necessity. In the instance cited by me I was careful to point out that, although no disbudding had been practised, the individual flowers were of good size, as, owing to the fact of the sap having been monopolised by the centre bloom on each shoot, some of the side buds had developed. Your correspondent says "I prefer to do my own disbudding, and do not leave it in this way to outraged Nature." How Dame Nature can be "outraged" by being left in every way to her own devices it would, I imagine, be difficult even for Mr. Tallack himself to explain. "To outrage" is of necessity a verb of action. That there was an absence of action in the case referred to by me that might possibly have merited the appellation of neglected I admit, but I did not observe that unassisted Nature (if I may be allowed to substitute the term "unassisted" for "outraged") had acted as though aggrieved by the omission of that beneficent mutilation advocated by Mr. Tallack. In fact, I considered, and still consider, that the results obtained were eminently satisfactory. I am not finding fault with the system of taking cuttings and potting them on. That is doubtless the most sure course to pursue, but at the same time it must be remembered that it is a course which entails a considerable amount of labour in potting, stopping, disbudding, and watering; whereas that of planting out the old stool and potting it up in October reduces the labour to a minimum, and in growing for market

cultivated by a rather small body of growers, and are so interesting as a group, that I have long been surprised to find that the rate of progress they have made is out of all proportion to their merits. When I say this I ought, perhaps, to explain that by the word "progress" I mean improvement in colour and in size only, for in form it is doubtful if any real improvement can be made considering the type of many of the old exhibition sorts. In the article above referred to will be found what may be taken as a generally accepted definition of an Anemone Chrysanthemum, although through an error of punctuation there is some little ambiguity in the second paragraph, the third sentence of which should read as follows: "It is essential

America for the purpose of crossing with the Japanese Chrysanthemum, with the result that many of the modern sorts have lost the neatness of form that distinguished their predecessors. We have now many Anemone Chrysanthemums of large size with long, ragged, drooping guard florets and discs composed of loose, open, tubular florets, that may be valuable so far as size is concerned, but which are not to be compared in other respects with the old Chinese type. Some of these novelties have really no pretence to the semi-spherical disc at all, and wanting this, upon which the beauty of an Anemone so much depends, they want all.

The variety Rider Haggard, which is reproduced here in a much reduced form, is one of

the labour bill has to be taken into consideration. The rough and ready way, in one case at all events, has answered well. Whether it can be depended upon to produce equally good results when carried out on a large scale I cannot say, but I hope this year to give both methods a fair trial, in order to be in a position to form a better opinion as to their respective values. When I wrote that a nurseryman had offered 4s. for the plant, I should have mentioned that this offer was for the flowers alone, and did not include the pot. Mr. Tallaek ridicules the idea that this price, or even double, viz., 8s., for the forty-eight blooms (averaging 3½ inches in diameter) would be remunerative. I can only say that thousands of such blooms were, to my knowledge, sold at less than 1s. a dozen last Christmas, and I should hold the wholesale grower who received over 2s. per dozen particularly fortunate, as this price would mean at least 3d. per bloom retail. Naturally, the profit depends largely upon the amount of labour expended on the plants during their period of growth, and where the sum total of this is represented by potting up and housing two months before the blooms are cut, 4s. per plant should leave a fair margin; and should 8s. be obtained, the grower, while failing to excite Mr. J. C. Tallaek's envy, would assuredly receive the congratulations of S. W. F.

— This serves two useful purposes. Cultivated on the orthodox plan of carrying three blooms upon each plant with one main stem, it is one of the best of early exhibition varieties. Managed upon the topping system, it is one of the best if not the very best varieties with yellow flowers for late work. When I say late I do not mean after Christmas, but as a December-flowering variety it is especially valuable. One market grower of my acquaintance grew several thousands of it last year, and intends to treble the number for the next flowering season—in fact has decided to grow no other yellow *Chrysanthemum* in quantity.—E. M.

## TREES AND SHRUBS.

### RARE TREES AT ESHER PLACE.

THIS beautiful and historic park, the residence of Sir Edgar Vincent, K.C.B., is within easy access of the metropolis, and the grounds contain not only unusually fine old specimens of our forest trees, but also a representative collection of some of the rarer conifers. The Oaks and Beeches are thriving unusually well in the light sandy soil of which the park is for the greater part composed, and not a few of these contain a large quantity of excellent timber, and rise with clean and well-rounded boles to from 70 feet to 90 feet in height. Hard by the famous Wolsey Tower may be seen many excellent examples of the English Elm, and which in the dampish alluvial deposit seem to find all that is necessary for their perfect development. Many of these reach to 90 feet, with clean columnar stems that girth in some instances fully 12 feet at a yard from the ground.

The pride of Esher is, however, its fine old Tulip tree (*Liriodendron tulipifera*), a specimen without a rival in this country, whether as regards size of stem or spread of its ponderous branches. At 3 feet from ground level the fluted stem girths 18 feet 7 inches, while the branches cover a spread of 78 feet in diameter. It is in the rudest health, as is amply demonstrated by the great wealth of the brightest and freshest of foliage and the entire absence of dead or dying limbs. When in full flower this tree is an object of unusual interest and beauty, the blooms being produced in almost extravagant abundance, while at present the curiously-formed, cucumber-like fruit renders the tree conspicuous in a marked degree. The long and lithe branches sweep the greensward in an easy and graceful manner and add quite a charm to the neatly-kept lawn. On account of the far-spreading limbs, many of which are when in full leafage fully a couple of tons in weight, every care has been bestowed so as to minimise the chance of any

of these splitting away from the main trunk, and iron rods have just now been added to the props previously in use, thus rendering the immense head perfectly safe for many a year to come.

At no great distance from the Tulip tree may be seen an unusually fine old specimen of *Magnolia grandiflora*, and which for some time back has been an object of general admiration on account of the large numbers of perfectly developed flowers with which the tree has been studded. Usually we find this particular species of *Magnolia* occupying some cosy corner by the wall side, it not being considered sufficiently hardy to use as a standard unless, indeed, in the milder portions of Southern England. The Esher specimen, however, stands quite alone, and looks healthy and happy in its isolated position. Many of the flowers are 8 inches in diameter, almost pure white and deliciously fragrant, though much too powerful for placing in a living room. It is by no means common to find the Indian Cedar (*Cedrus Deodara*) in cone, yet a well-furnished specimen in the park is at present bearing large numbers of full-sized and perfectly developed fruit.

The pinetum is also well worthy of a visit, for there may be seen such rare trees as *Cunninghamia lanceolata*, the dwarf *Weymouth Pine* (*Pinus Strobus nana*), the weeping *Indian Juniper* (*Juniperus recurva*), the curious dwarf *Mountain Pine* (*P. Moghus*), the *Canadian Hemlock Spruce* (*Tsuga canadensis*), as well as numerous species of the less common *Junipers*. Such large growing trees as the *Douglas Fir* (*Pseudotsuga Douglasii*), the *Mammoth Tree* (*Wellingtonia gigantea*), *Sequoia sempervirens*, *Thuja gigantea*, *Picea Menziesii*, and the *Austrian and Corsican Pines* (*P. austriaca* and *P. Laricio*) are represented by finely developed specimens, the two latter being of unusual height and girth of stem. The curious and rare *P. longifolia* is likewise well represented.

Amongst shrubs, the *Strawberry Tree* (*Arbutus unedo*) flowers and produces fruit freely, and seems quite at home in the light sandy soil in which it has been planted. The *Myrtle* may also be seen growing freely enough against the garden wall, and where, judging from its size, it must have been for very many years. *Laurustinus* flowers freely, and attains to such a size as we rarely see except in the ozone-laden atmosphere by the seaside. Peat-loving plants also grow fairly well, and not a few good examples of the commonly cultivated *Azaleas* and *Rhododendrons* are to be found. The old *Mulberry tree* in the kitchen garden is worthy of note, it being a robust, healthy specimen, with as fine a head of dark green foliage, just now relieved by the showy fruit, as could be wished for.

Altogether the trees and shrubs at Esher Place are of unusual interest, and the collection will shortly be augmented by other worthy representatives of the family. A. D. WEBSTER.

**Magnolia macrophylla.**—The interesting and exhaustive article on the *Magnolia* family that appeared a short time back in *THE GARDEN* would seem to render any reference to individual members of that family somewhat superfluous. Yet I should like to call attention to the particular kind named at the head of this note, because, although its unique foliage renders it specially valuable for ornamental planting, it seems to be a comparatively unknown tree. Although requiring a sheltered spot it is perfectly hardy, the specimen here being rather over 30 feet high. In the distance the foliage looks almost like small leaves of the *Musa*, individual leaves averaging 15 inches in length by 6 inches in breadth, and there is a glaucous under-surface, reminding one somewhat of the *Eucalyptus* family. The flower is remarkable for its size, being from 8 inches to 10 inches in diameter, but otherwise has nothing to recommend it. The petals are very flimsy and dirty white in colour. It is a deciduous tree, late in putting on its foliage, and given a mild autumn, a proportionately late leaf-shedder, more so than its smaller foliated allies, as, for instance, *acu-*

*minata* and *glauca*. I should like to recommend it to the notice of planters as an ornamental tree for small lawns. Planted, for instance, at the head of an open glade, where it is backed by trees of larger growth, it is a wonderfully distinct and striking feature. In common with other beautiful foliated trees, it is certain that it might be used with advantage where unique summer foliage is required in lieu of costly and tender subtropicals. The paragraph noting its hardness, and, at the same time, the necessity for a sheltered spot, may read contradictory, but it has reference to shelter from wind in exposed situations. Heavy gales are apt to split and tear the foliage and to spoil the general appearance of the tree.—E. BURELL, *Claremont*.

### FAIR WEATHER EVERGREENS.

A FRIEND writes from Ireland: "Six inches of snow here now and 10' to 15' of frost nightly. Half-hardy things will go off by the hundred, but it is a blessing to get a garden purged, as it were, every ten or fifteen years at least." We do not look upon this kind of prospect with at all the same complacency as our friend, because of the ugliness which must result from deaths in severe winters, owing to our very common practice of planting so many evergreens. If they were really hardy evergreens it would matter less, but more than half of them are not hardy in very hard winters, except it may be in sheltered valleys and light soils of the English sea coast. There is so much sea coast, however, as to allow a large margin for escape, but even our commonest evergreens are killed in the central parts of the country both in Ireland and England, not excepting the common *Laurel*. This, however, we could well spare, because in many places we have ten times too much of it. No doubt some of the evergreens that we try to have, and occasionally suffer so much for, are worth a chance, such as the *Bay* (which is the true *Laurel*) and the *Laurustinus*, though we have seen these killed on the shore, even in warm *Sussex*. The lesson to be learned from such winters is that those who plant their gardens with any thought of anything but the common nurseryman's rubbishing mixture—*Privet*, *Laurel*, &c.—should remember that there are hardy evergreens as well as tender evergreens, and that the noblest of them are natives of Britain, like *Holly*, *Yew*, *Ivy* and *Juniper*. It is difficult to pick out of other countries anything quite as good as these until we go to the *Pines*, like the *Silver Fir* and the *Cedar of Lebanon*, because a good many of the *Californian* conifers are not fit to endure such winters as this, and even the *Corsican Fir*, with all its good qualities, is occasionally killed towards the north of France. Many *Californian* conifers will do in various parts of the country. Some places are kinder to the *Douglas Fir* and the *Wellingtonia* than others, and here and there they seem to do very well; but this fact is not nearly so important for us as to find out the evergreens of other countries that may really be trusted in ours. Considering the cost and care of choice plantations, it is a poor return to wake up some spring morning and find them all either dead or half way to it.

Another friend writes from France that at Cannes the gardens have been "destroyed by 8° (C.) of frost and 1 foot of snow. People there never saw such a calamity." This should be a lesson to us as well as to the people of the south of France, who are continually trying to give to their hard white villas an absurdly tropical look with all sorts of delicate *Palms* and *Aloes*, instead of developing the many beautiful things, not omitting their own *Heaths* and native bushes and trees like *Hex*, which are quite hardy and beautiful there. One of the few really beautiful gardens we ever saw there was that of the *Comte de Paris*, which was almost abandoned to the tree, *Heath*, and other delightful plants of the coast. However, people rarely think of the beautiful things of their own country, but are always trying how far they may go with exotics, and so have to pay for their ways now and then.—*Field*.

## STOVE AND GREENHOUSE.

## LACHENALIAS IN BASKETS.

OF late years more attention has been paid to Lachenalias, so that we have some beautiful hybrids and seedlings quite distinct from the older forms. The kind illustrated (*Lachenalia tricolor*) makes a charming basket plant, and Lachenalias are not grown in this way so much as they deserve. We have so few flowering plants at this season of the year which do well in baskets, that it is surprising the stronger-growing varieties are not more grown in this way, the flowers lasting long and the plants of simple culture. The illustration depicts a charming basket of Lachenalias, the drooping leaves and flower-spikes having a more natural aspect than

grown in baskets give ample width between the wires, as the growths can readily push out at the sides of the basket. I have some very light baskets, home-made, with a few cross supports and strong rim, the other portion being 2-inch wire netting. A good effect can be got by using two or three varieties if sorts are selected which bloom at the same time. The baskets should be lined with fresh Sphagnum Moss. I prefer live Moss, as if the bottom of the basket be damped when suspended, it presents a neater appearance than dried Moss. Use a compost of turfy loam, dried cow manure and sharp sand. If the loam be heavy, use a portion of leaf soil. Lachenalias should be put into boxes or pots in August before the new root-growth commences. Give free drainage and grow them in a cool house or frame, as they

*Lachenalia tricolor* in a hanging basket. Engraved for THE GARDEN from a photograph sent by Mr. F. H. D. Kemplen, Dunedin, N.Z.

when the plants are grown in pots. For baskets, *L. tricolor* is one of the best, having bold leaves, dark green spotted with dull purple, and about 1 foot in length when the bulbs are well grown. This kind blooms early in March, the flowers being of bright colour. *L. Nelsoni* and *L. luteola* bloom early and are of great beauty, being in advance of the one illustrated, so a succession of flower is obtained. These kinds differ in the colour of the bloom, the first named being a newer hybrid than *L. tricolor* and has golden yellow flowers. *L. luteola* is well worth growing in all collections. *L. pendula* is of more drooping habit than those named, the flowers being of a deep purple-red and yellow colour, set on a stout stalk and drooping. This is one of the showiest of the species, but not better than *tricolor* for baskets. There are many others, but those named are best for baskets. Lachenalias can be grown in frames and with little heat. When

winter best in a structure just free of frost. The plants in baskets are placed in a cold fernery, pot plants being grown on a cool ash bottom in cold frames. Those who may not have the space to grow these in baskets at the start may readily use 9-inch or 12-inch pans and then place in shallow baskets in January, or the pans may be suspended. It is not necessary to disturb the plants in baskets every season, as if they are well fed they like frequent supplies of liquid manure when growing. Dip the pans or baskets in water once or twice a week and thus keep the flowers dry. When in bloom Lachenalias enjoy a cool house, plenty of light and moisture after flowering. They require ripening by free exposure to light and less water. When the leaves die away store them as cool as possible, keeping quite dry till potting time, when the bulbs should be shaken out, sorted into sizes and potted up. W.

## TREE CARNATIONS.

THE note by "J. C." at p. 128 suggests a few remarks on this, one of the sweetest and most desirable of all our garden plants. Duke of York is the most beautiful of all the Tree Carnations in its colour of rich deep crimson, surpassing Uriah Pike. It is a taller growing plant and does not produce so many flowers. The flowers are well formed and not very liable to burst. "J. C." seems to fancy that Uriah Pike will not make much "grass." This surmise is incorrect. Uriah Pike makes grass more freely than most of the Tree Carnations, but in its growth it does not run up so freely as some others; consequently it does not produce pipings very freely from the main stem. Although I much prefer the individual flowers of Duke of York to those of Uriah Pike, still in some respects the latter may be considered quite as valuable for the garden. I do not disparage it, and in our own garden we grow equal quantities of both, and recommend my friends to grow both of them.

I am growing as many as I can get of the lovely pink variety *Mlle. Terese Franco*. It is an Italian seedling, and it grows very freely, being also most useful for winter blooming. I do not know any white variety more free than *Mlle. Carle*; the flowers will occasionally come with a slight dash or line of white in the petals, but when the flowers open at midwinter or in January and February, they are generally pure white. More vigorous in growth, but producing fewer flowers, are *Purity* and *Mrs. Moore*; they resemble one another greatly, and I do not know that it is necessary to grow both. They produce lovely pure white flowers. I must not omit *Miss Joliffe*, although I grow one under the name of *Miss Joliffe Improved*. How it came to be improved I cannot say, but the improvement seems to be on paper only. *Winter Cheer* is yet (I think) the best scarlet for flowering in winter, but a variety named *Zouave* gives larger and brighter flowers in spring. *Mrs. Lewelyn* is a very handsome pink or rose-coloured variety, and altogether distinct from *Miss Joliffe* or *Terese Franco*. It does not produce so many flowers, nor is it so good for midwinter flowering, but lovely in the spring months.

Now is the time to get up a good stock of plants by cuttings or "pipings," to use the phrase of the florists. Shakespeare uses a better word, "slips." "I'll not put dibble in earth to plant one slip of them," quoth *Perdita*, but she had lost her temper, for were they not "the fairest flowers of the season?" They are slips; the small growths slipped off from the axils of the leaves are the best, and they are merely dabbled into small well drained pots of fine sandy soil, the soil being pressed firmly around the base of the slips. At this time of the year they do best in a propagating house with a little bottom-heat; and to make sure of their striking well, they ought to be placed in a frame or glass light inside the house, but if none of these appliances are available, a square or two of glass should be laid on the tops of the labels. The object is to retain the moisture about the slips until they have formed roots. Practical gardeners know well how to manage such slips and the young plants after they are repotted by carefully inuring them to a light, airy greenhouse temperature, and exposing them to the frames and ultimately to the open air, for these slips put in now will not produce their flowers until late in the autumn and winter. Amateurs and others with but little experience in the culture of any kinds of plants make mistakes, which, though apparently very trivial to all appearance, may be productive of disaster. They are most likely to err in subjecting the young and tender plants too suddenly to changes of temperature, which may give them a check from which they would not be likely to recover. Another cause whereby injury might result to the plants is carelessness in repotting them. The newly-formed roots are, indeed, very tender, and more brittle than glass or egg-shell porcelain, so that great care is necessary in planting each one separately in what are termed thumb pots. I plunge the pots in bottom-heat again for

planting in beds are many of them admirably suited. I allude to such as Early Gem, ferrugineum, fragrans, and others of like habit. Andromeda and Kalmias in the atmosphere of towns and cities are of none too thriving a character. Where they will succeed, Andromeda japonica, A. arborea, and A. speciosa, with Kalmia angustifolia pumila and K. a. rubra, K. glauca and K. latifolia, with its variety K. l. myrtifolia, are all worthy of planting in beds. To these the hardy Heath and Menziesias will form excellent edgings. Such beds also form capital positions for growing different varieties of Liliium, including L. auratum. Aralia Sieboldi must not be overlooked for use as specimens or to group with other subtropical plants (it may not be hardy in all positions). Mahonia Aquifolium may be turned to good account for shady spots where an attempt to grow tender plants would end in failure. Daphne Cneorum should be added to the list with the dwarf Rhododendrons. Escallonia macrantha can be used for beds by pegging it down if that be desirable. E. Phillipiana is another species that can be recommended. In Euonymus radicans variegatus we have a most valuable edging plant, which ought to take the place of many a tender subject. It is propagated as easily as the bedding Calceolarias, and is one of the hardiest of its race. As a permanent edging it can be strongly recommended. Another splendid and most effective plant for edgings or massing is the best form of the Golden Privet (Ligustrum ovalifolium elegantissimum). This will undoubtedly be grown far more as its merits become known. Another excellent variety is L. lucidum tricolor. Olearia Haasti makes a fine display when grouped; its culture, like that of many more Japanese shrubs, is increasing. As a border plant Osmanthus ilicifolius is gaining in favour, being in addition a reliable town plant. The Golden Yew (Taxus baccata elegantissima) makes a splendid feature for a long time during the summer, a few plants grouped together having a rich appearance; it is also amenable to clipping, so as to form close edgings. In the Retinosporas alone there is quite a wealth from which to choose: the forms of R. obtusa, R. plumosa, R. filifera, and R. ericoides afford a splendid choice in various shades of colour. Cupressus Lawsoniana lutea is one of the best of all golden conifers, whilst in the various tints of other forms of the same species there is an abundant choice for colour effect. The extended planting of Evergreens of all kinds in gardens around London and other populous centres should be still further increased. My reason for giving this advice is because many of the Fir tree family are failures; old trees hold on, it is true, but to plant many young ones would give but poor results.

Upon referring to deciduous trees and shrubs we shall find also a great variety, the culture of which may with advantage be made more general. Of these I shall allude to the variegated or richly coloured forms chiefly. Our old friend Negundo fraxinifolia albo-variegata (the silvery Maple), as well as N. f. aureo-variegata (the golden form), are often seen in shrubberies, but when massed they produce a much finer effect either by themselves or when associated with other things as a contrast. Prunus Pissardi planted with the silvery Maple is a case in point, not crowded together, but with sufficient room between each plant for light and air to do their part. Such planting as this can be kept in bounds by annual prunings in both instances. Planted thus there is scope for an undergrowth of flowering plants. Calceolarias (yellow), Violas and Salvia patens are examples of what may be used. I have quoted La France Rose for bedding purposes. Supposing these, however, to be half-standard instead of dwarf plants and then plant between them such a Rose as Perle des Jardins, which, in addition to its beautiful yellow flowers, has deep bronzy-tinted foliage, we have another illustration of what may be done. Surely such a bed is better than one composed of scarlet or pink Geraniums, or even one of Colcus Verschaffelti. Cornus san-

guinea albo-variegata is another hardy plant well suited for massing. As a contrast thereto one or more of the Japanese Acers could be used; such, for instance, as Acer palmatum, A. palmatum atro-purpureum, A. dissectum or A. sanguineum, all of which are beautiful subjects when in foliage. This list of Acers could be extended, but those given are a few of the best. In large gardens, with plenty of scope for effect at a distance, the Golden Alder (A. glutinosa fol. aurea) might be planted. Berberis Thunbergi makes a splendid show of richly coloured foliage in the autumn months, being then very useful in a cut state to arrange with suitably coloured flowers. Besides the one Cornus already quoted there are other kinds worthy of note, as C. brachypoda variegata, a Japanese form, the type of which has the foliage of a deep crimson in the autumn; C. mas elegantissima aurea is of smaller growth, but very pretty; C. atro-sanguinea should also be noted. In the Copper Nut or Filbert we have another plant with dark foliage, which would contrast well with such as the variegated Acers. Of this I note there is also a golden variety. The Copper Filbert has been in cultivation many years, but seems to have escaped notice. The Golden Elder (Sambucus nigra aurea) is of quick growth; in many places I have seen it very effective in masses. Another variegated plant, Symphoricarpos vulgaris variegatus (the Snowberry) is worthy of notice for cutting, whilst I think it would also be amenable to pruning; in a cut state I have seen it very beautiful.

#### OTHER PLANTS.

As a dividing line to large beds I have seen Cotoneaster microphylla used with the best advantage; its use as a wall plant is well known. Alluding to wall plants, I am reminded of the Everlasting Peas, the culture of which is none too common. Wall plants are often neglected.

TENDER BEDDING PLANTS IN SMALL GARDENS, &c.—In small gardens it is my opinion that tender plants should be used considerably less, speaking proportionately, than they are even in larger ones. There are several reasons for this, not the least important being that of overcrowding whilst under glass, which has already been alluded to. In small gardens every part of the place comes more immediately under the eye; it is, therefore, of the greatest importance to have no more bare places from October until the end of May than can possibly be avoided. This can be provided for, it is true, by raising Primroses, Polyanthuses, Pansies, Wallflowers, Forget-me-nots and several other good things. This should as far as possible be done in every garden, but it is oftentimes left undone. These spring and early summer plants for the flower garden are both suitable and welcome in any garden, be it large or small. The complaint is sometimes made that in their use the summer bedding is delayed; this may be so in some instances, as in the use of too many Wallflowers. Primroses and Polyanthuses, however, would be over, so would the Forget-me-nots, whilst in the case of Pansies, which go on flowering for a long time, it is quite possible to plant the summer stock between them when these latter are plants of suitable character. Begonias could be managed in this way; so could Geraniums and any other but the dwarfest of plants. The one point to pay attention to is that of thoroughly preparing the beds in the autumn when this is to be done, and overcrowding in the case of the Pansies should be avoided. Early flowering bulbs are most attractive, but instead of planting them in beds I would prefer them in borders where they can remain after flowering rather than have to disturb as soon as the flowers have faded. This latter subject of beds in small gardens reminds me of one feature which in many a garden is too prominent—it is that of too many flower beds. Rather than have so many beds I would personally prefer to see the borders extended in front of the shrubs. This would allow of a greater expanse of turf, a most desirable feature without a doubt, thus enhancing the effect. To dot beds about upon a small lawn is

oftentimes meaningless, and all the more so if they happen to be of some fantastic shape. Tennis and other outdoor games have to be considered. These recreations could without a doubt be all the better provided for if the beds were fewer in number. The reduction in the numbers of the flower beds in many a large garden would be an advantage without a doubt. In looking through an illustrated book of the seats of the nobility and gentry, published in 1829, there is one most remarkable feature, viz., the absence of flower beds as compared with present day gardening in this respect. This might possibly be the other extreme, but surely an excessive display of flower beds is the worse of the two. A broad expanse of turf in front of the house is restful to the eye; this I should personally much prefer to any undue amount of colour. Clothe the walls of the house by all means with climbers and wall plants of sorts to suit the taste. Of these there is an abundant choice, so that no excuse can be made on this score either from point of flowers or of foliage, of evergreens as well as deciduous subjects.

There are other things to which allusion could be made in which hardy plants play an important part, such as Delphiniums, Peonies, Hyacinthus candicans, with a host of other bulbs, not forgetting even the Narcissi or Daffodils. Dahlias, again, have not been touched upon; still we cannot afford to miss them, more particularly the Cactus, the pompons, and the singles. These are easily propagated, taking no previous room under glass. Iceland Poppies should have been included; they are particularly useful. Cannas do not take a great amount of room, and then only from the time of starting; this latter item may in favourable spots be dispensed with by planting straight away in their summer quarters. Anemone japonica should be added to the herbaceous plants, whilst rockwork is quite worthy of an article to itself. The deciduous Magnolias have rarely had that attention bestowed upon them which their good qualities deservedly merit. It is impossible in this short space to name many things. Roses could be extended into a separate article. My chief object has been to give examples of what may be used as well as of methods that can be adopted. H.

## GARDEN FLORA.

### PLATE 1004.

#### THE GINGER-WORTS.

(WITH A COLOURED PLATE OF COSTUS SPECIOSUS.\*)

The Ginger-worts (of which this is one) are as a class very little known in gardens, though there are some beautiful flowering plants among them, of which especial mention may be made of the members of the genus Roscoea, Curcuma, Alpinia, Hedychium, and others, as well as Costus, one representative of which,

COSTUS SPECIOSUS, is herewith figured. This forms a mass of thick roots, from which are pushed up stout Bamboo-like shoots, but of a succulent nature. The largest leaves are a foot or nearly so in length and 4 inches to 5 inches wide, smooth on the upper surface and silky beneath. They are arranged in a spiral manner on the stems. The mode of flowering is very well shown in the accompanying plate, the stout stems being terminated by the red cone-like arrangement from whence the flowers are produced. The individual blooms do not last long, but a succession is kept up from one head for a considerable time, and in the case of a good flowering specimen the contrast between the large white flowers and the reddish bracts is very striking. The stems of this Costus reach a height of 4 feet to 5 feet. It was introduced from India as long ago as 1799.

\* DRAWN FOR THE GARDEN by H. G. Moon in the garden of Mr. Bennett-Pee. Lithographed and printed by Guillaume Severeys.

*C. IGNEUS*, the next to mention, is a remarkably showy member of the genus and supplies a colour but little represented among stove flowering plants. It forms, as does the last-named, a dense leafy clump, while the blossoms are also borne in cone-like heads. They are 2 inches or nearly so in diameter and of an intense deep orange colour. Like those of *C. speciosus*, they are thin in texture and do not remain long in perfection, but another point in common with the two is that a continued succession is maintained for a time. This *Costus* may be planted out in a warm house or grown altogether in pots; in either case, but more particularly with a large specimen, it will at times flower more or less nearly throughout the year. At Kew its bright coloured blossoms may be often seen. It was awarded a first-class certificate by the Royal Horticultural Society in December, 1893, the specimens being exhibited by Sir Trevor Lawrence. *C. igneus* is a native of Bahia, from whence it was introduced by M. Linden in 1882.

*C. AFER* is in general features after the manner of the two preceding. The leaves, however, are narrower and the flowers are somewhat smaller, their colour being white, with a yellow blotch on the lower segment. As a rule it is not so free-flowering as the other two. It is a native of Sierra Leone, and was introduced in 1821.

*C. MALORTIENSIS*, a species with golden yellow blossoms, sent to this country from Costa Rica in 1860, was figured in the *Botanical Magazine*, t. 5894, but whether it is now in cultivation I cannot say.

*C. MOSAICUS* is a decidedly ornamental plant from a foliage point of view, but the flowers I have not seen. In this the obliquely lanceolate leaves, which are about 4 inches long, are arranged in a spiral manner on succulent stems. The major portion of the leaf is of a silvery grey tint, arranged after a mosaic pattern, while in the centre is an irregular shaped band of dark green. Several other kinds are known; in fact, the genus consists of about twenty-five species, but very few of them are at present in cultivation.

#### CULTURE.

The culture of these different species of *Costus* is simple, they being all moisture-loving plants, that need a good free soil to root in. *C. speciosus* does well at Kew, and I once (though some years ago) saw it very fine at Glasnevin. *C. igneus*, too, used to be remarkably showy planted out in the Water Lily house at Pendell Court, as in the boggy soil there it grew rapidly and flowered nearly throughout the year. It will, however, succeed and flower well in pots treated much the same as the general run of stove plants, but with pretty liberal attention in the matter of water. A yellow turfy loam, lightened by leaf-mould, well-decayed manure, and sand will suit it well. A glass structure kept at a tropical temperature, and so arranged that the occupants may be planted out with an unlimited water supply, might be made an object of great beauty and at the same time furnish a very uncommon feature. Besides the *Papyrus* and *Nelumbium speciosum*, which at once suggest themselves, we have some of these species of *Costus* and several other allied plants. Thus *Alpinia nutans*, with its nodding racemes of beautifully marked blossoms, and the distinct *A. nutica* would be just at home, and so would the *Hedychium*s, particularly *H. coronarium*, with its large white, sweet-scented flowers. H. P.

**Greenhouse Dracænas.**—Of these there is a good variety as regards size of plant and style of growth, it being an easy matter to adapt one or the other in various sizes to nearly every form of decoration either under glass in cool houses all the year, or for half the year outside in favourable positions and the other half inside. *D. australis* is a very variable plant. The type has long and comparatively narrow leaves with green midribs,

being very graceful even in a small state. *D. australis* Veitchi differs in having the midribs of a bronzy red shade, and is slightly more robust on the whole. *D. australis lineata* is a plant of noble growth, with its leaves twice or thrice as wide as the species. As a decorative plant in a tall house this makes a grand subject. *D. australis variegata* (to simplify the name of *D. Doucetti*) requires more warmth than that of the ordinary cool house, so as to retain its true character, then it is a handsome plant. *D. rubra* (so named from the colour of its flowers) is one of the hardiest of decorative plants: of this there is also a bronzy-foliated form when the foliage is developing, making it quite distinct from the species. *D. congesta* makes a charming vase plant in a small state, also as a table plant, but its culture is much neglected.—G.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**TRANSPLANTING PEAS.**—Batches of Chelsea Gem selected early which were sown in small pots in December and placed at once in cold frames, being well protected during the recent inclement weather, will now be thoroughly hardened off, and should stand the ordeal of transplanting well. If, according to advice given in a former calendar, the snow was removed from Pea borders as soon as the thaw commenced, the turned-up soil will by this time have become sufficiently warmed to promote root action. In planting do not mutilate the roots, but merely part the ball in the centre, place them in the shallow trench, gently pressing the soil round the roots, and at once protect from cutting frosty winds by wooden troughs or small Fern boughs. As a guard against sparrows I always employ small irons similar to those used in the game of croquet; these are placed along the rows at intervals. Thin twine is then stretched from one to the other until a perfect arch is made. As the Peas increase in height the irons are raised until the sticks are put to them. Where the ground is not so warm and light as desirable, a quantity of finely sifted soil or that obtained from beneath the potting bench may be worked in amongst the roots. In very sheltered gardens the Peas may be stuck as soon as planted, a net being thrown over to keep sparrows at bay. Plenty of small twigs should be used between the main stocks to prevent the haulm falling through and also to act as a shelter. Those that were not raised until January, and then in heat, will need extra care in the hardening off, it being wise to wait a week or ten days longer before transplanting rather than to incur any danger of injury to the tender tops.

**SUCCESSIONAL SOWING.**—The season being so far advanced, open-air sowings may be made without fear. As second earlies could not be sown early in February owing to the frost-bound character of the soil, they may now be got in, and with greater certainty of doing well, the sun's power now being considerable. In this section Exonian and Criterion are as satisfactory as any, the former being ready for gathering a week or so before the latter. To follow these some of the larger wrinkled Marrows may be sown—Stonebridge Marrow, Duke of Albany, Exhibition Marrowfat, and Prodigy, all being excellent. If ground can be spared a width of 5 feet or 6 feet should be allowed between the rows, this allowing for rows of Spinach between to grow freely without being trampled upon. If the position is open and sunny, the small forcing varieties of Cauliflowers may also be grown between. By all means avoid sowing thickly, although this season, owing to the indifferent harvest of 1894, rather thicker sowings than usual will be advisable, thinning later on if too crowded. The above varieties being of a very branching habit, ordinary drills should not be made, but openings taken out with the spade. A row or two of that good old Pea Stratagem may

also be sown now. It is of a most convenient height and of grand flavour, continuing to form pods over a long period. On poor shallow soils trenches may be taken out and well lined with manure, always providing the situation is not low. Where this is the case moderately deep drills are the safest, a good mulch of rich manure being given when the Peas come into bloom.

**BROAD BEANS.**—Early batches raised in heat and duly hardened off will be ready for removal to the garden by the third week in March. Sowing in small pots is a great advantage, as then they can be placed in position with little or no root disturbance. Plant in shallow drills, drawn out if possible in the early part of the day and exposed to the sun's rays until the afternoon; afterwards gently draw and press the soil around the balls, and give protection in the same way as recommended for early Peas. These rows will afford full sized pods some time before even the autumn-sown Mazagans or January-sown Green Windsors. Another and rather extensive sowing should now be made where this class of Bean is esteemed through the summer months, and, instead of drawing drills, dibble the Beans in rows 1 foot apart and 6 inches between the seed. This non-disturbance of the ground, which should be solid, by reason of having been dug in autumn, will enable it to retain moisture better. At this time several varieties should be sown in order to secure a succession. Seville Longpod, still one of the most profitable and best flavoured Beans; Veitch's Improved Longpod is also a capital variety, containing more Beans than the majority of extra long-podded sorts. Where large Beans are an objection, the dwarf and free-yielding Beck's Green Gem may be sown. This variety is most convenient, as being dwarf it does not fall about like the others and the Beans are small and deep green in colour, this rendering them especially useful for the dining room.

**SOWING SMALL SEEDS.**—In all but the latest and coldest districts the earliest open-air sowing of Cabbage, Cauliflower, Lettuce, and some of the earliest Broccoli may be made, also Leeks for a late supply. If the autumn-planted hand-light Cauliflowers have passed through the frost safely, they will be closely followed at the beginning of July by Walcheren raised in boxes in heat or sown in the early Carrot frame. Seed of Walcheren, Pearl, and Eclipse sown now on a sunny aspect and in a warm soil will keep up the supply from the beginning to the end of August. Autumn Giant may likewise be sown for coming in during September. Broccoli, which take a long season of growth, such as Cooling's Matchless Spring, Snow's Winter White, and Backhouse's Winter White, a splendid variety, may also be got in. Cabbage to follow spring heat-raised plants may be represented by Ellam's and Enfield Market, these two following each other in the order named. The main sowing of Brussels Sprouts must now take place. These may comprise Veitch's Exhibition, Paragon and Northaw Prize. Where early Savoys are in demand a sowing of Early Dwarf Elm and Green Curled will be advisable. Lettuce, both of the Cabbage and Cos sections, must also be included, small plantings of these at all times being preferable to large lots, many of which spoil before they can be eaten. I have found Alexander Cos to be a most excellent variety for hot summer weather, not bolting like many others, and developing large luscious heads in a very short space of time. Hick's Harly is another good sort, doing well if planted on a cool east border and in rich soil. Of Cabbage varieties, Continuity, Perfect Gem and All the Year Round are reliable, and good Lettuce must be thinned freely immediately the seedlings can be handled, or they soon spoil. Indeed, the same remark applies to all the above-named subjects.

**PARSLEY.**—If a good breadth of this is sown now on warm, well-drained soil, plenty of seed being used, it will afford a supply by June, when much of the winter beds will be running to seed. Moreover, if sufficient is left at thinning time, half the quantity may be transplanted several weeks later, this carrying on the supply till autumn, at

which time midsummer-sown batches will be ready for use. After sowing, sprinkle a good quantity of wood ashes in the drills, as Parsley is very liable to attacks from wireworm and grubs. That sown in heat in January will need gradually hardening off, so that early in April it may be transplanted in sheltered positions by the margins of walks or in front of espaliers. Frame-covered beds which have been closely picked may now have the soil between the rows loosened with a fork, after which all yellow leaf-stalks should be picked off and a dressing of artificial manure given. This, with increased sun heat, will soon induce the formation of fronds fit for use.

**SOWING HERBS.**—The present is a good time to sow such herbs as are not easily increased by division. On some soils also, especially in rainy springs, many offsets after planting die off, leaving sad gaps. These may be duly made up in June from plants raised from the present sowing, not planting singly, but grouping three or four plants together. The common and Lemon Thyme quickly germinate in heat, as also do the summer and winter Savories. Marjoram and Basil must also be included. An intermediate heat suits them best, and as soon as the seedlings appear, a warm frame from which the lights can be removed in fine weather. Where Lavender is esteemed, this may be increased by transplanting any of the lower offsets which may have rooted into the soil. These will grow away quickly and soon form fine bushes.

**CHILIES AND CAPSICUMS.**—In some establishments these are valued for kitchen use and pickles. Now is the time to sow the seed. A good strong heat is needed, and as soon as the seedlings can well be handled pot on, finally fruiting them in 6-inch pots and in an intermediate heat. Mammoth Red and Long Red are the best forms of Chilies, Capsicums being best represented by Monstrous Red, Prince of Wales, and Little Gem.

**TURNIP-ROOTED BEET.**—Where salads are in constant demand early Beet are essential, and as the long-shaped varieties will soon lose their virtue by growing away at the crowns, a row or two of the Egyptian Turnip-rooted may now be sown in an open sunny position. Where this cannot be afforded sowing must be deferred until the first week in April. Sow in very shallow drills and use a little wood ashes as recommended for Parsley. Sow plenty of seed, as independent of the liability to rot at this early date, Beet seed was not harvested in the best condition last autumn. I have sometimes sown early Beet in a box in warmth, gradually hardened them off, and transplanted them at the end of April with good results. In this case the young plants must be protected by small evergreen twigs.

**OPEN-AIR TOMATOES.**—The present time is in my opinion the most favourable for sowing Tomatoes for fruiting against walls out of doors. Some advocate earlier sowing, but in nine cases out of ten fine weather has to be waited for, and the plants become half starved and yellow, sometimes remaining for weeks in a stubborn condition after planting. If seed is sown now in a temperature of 60° at night, and the plants afterwards grown on under similar conditions until after the first shift is given, a sunny greenhouse will then suit them well for a fortnight, after which cool frames well protected by mats at night, cautiously aired until the middle of May, and fully exposed by day from then to the first week in June, they will then stand removal to walls with impunity. Of course some plan of protection must be devised, as the nights during June are sometimes cold and liable to injure the young succulent growths. Strong sticks, having their bottoms thrust into the ground and the upper ends resting against the wall, these being surrounded by mats at nightfall, are an effectual screen. Sow in single pots, not in boxes. In regard to varieties, there are several more suitable for outdoor culture than others. Amongst these the old Dwarf Orangefield is, in my opinion, still about the best when it can be obtained true. It is a hardy free grower, short in the joints, and yielding enormous clusters of fruit

from summit to base. Although not so symmetrical as the Perfection type, its flavour is of the finest. Laxton's Open Air and Sutton's First Crop are also both excellent for the purpose. Amateurs and others who have no walls may with every confidence plant against boarded fences facing south and shielded from cutting winds from east and west.

**SKROUTING LATE POTATOES.**—These in many instances have been hard hit with the intense frost, especially where the mounds were insufficiently covered with dry material previous to laying on the soil. The weather now being favourable, the whole stock should be overhauled, all frozen tubers removed, and the sound ones snibbed for the last time. If they can now be spread out somewhat thinly in some well-built shed and lightly covered with dry straw, the sprouts formed after this date will be of good length by the time planting takes place. If mild weather sets in between now and that date, the straw had better be removed altogether, the light increasing the strength and vigour of the new growths.

J. CRAWFORD.

### FRUIT HOUSES.

**EARLY PEACHES—STOPPING AND DEBUDDING.**—The weather during the past month in most parts of the country has been unfavourable for fruits requiring much sunshine and little fire heat in their early stages. Disbudding with very early forced trees cannot be commenced too early, at the same time removing surplus fruits and laying in a good foundation of wood for succession or extension of the trees. Disbudding will require daily attention, and is an important point in the culture of the Peach or Nectarine. Remove foreright shoots first, especially those near the ends of the shoots, or what may be termed the strongest growths, afterwards removing those on the lower portion. Take those shoots last which require pinching or what may be wanted to assist the fruits, stopping the shoots to the third leaf when close to the fruit. In disbudding, the grower must allow sufficient space for the development of the trees, as crowded wood means small fruits and much trouble from insect pests. Shortening back shoots before they attain much strength gives those which are required to be laid in at full length more room to develop, thus ensuring a mature or good fruiting wood for next season. If there be room for these shoots, reserve a shoot as much as possible on the upper portion of the branch, and as the flow of sap is always to the top, regulate the growths so as to get a good portion of strong wood at the base of the tree. My method is a simple one as regards extension of young trees. If a free growth be allowed for furnishing the trees, grossness is checked, and young trees the following season will carry more fruits. There will be less need, too, of the severe pruning often required to check undue luxuriance.

**SELECTION AND THINNING OF FRUIT.**—The thinning of the fruits is somewhat similar in detail to disbudding, and requires almost daily attention, healthy trees always setting far too much fruit. The modern practice of thinning the flower-buds before they open is excellent, but, of course, beginners need to exercise care at the start and remove a few of the thickly placed buds where signs of dropping are evident and the varieties are sure setters. Of course, these remarks do not apply to early trees at this date, but can with advantage be practised with those in succession houses. In their case there should be no fear of dropping, and the trees are often much weakened by setting far too many fruits. In the selection of fruits intended to mature when the flower-buds have been thinned previously the cultivator's task is much easier, as those buds which set are larger. A few soon take the lead, and are readily recognised as being better than others. In the final selection the best fruits as regards size, colour, and flavour are those on the upper surface of the trees when trained to the roof or over a semi-circular trellis, whilst those on back walls

should be prominent or face outwards, as the fruits are often deformed when left close to wires or pressed by growing shoots.

When finally thinning out the fruits, reduce all double ones to one at each eye or bud. Remove all badly placed fruits, and as regards the quantity of crop each tree should bear much depends upon the condition of the trees. Many growers crop freely and feed liberally, annually paying great attention to the trees, keeping the roots near the surface and feeding. The old regulation as to cropping was a fruit to every square foot of top-growth, and it has much to commend it if a fair crop of fine fruits be desired. When the fruits are swelling, syringe the trees overhead twice daily, moistening all portions of the trees, especially the upper portion, this being most exposed to sunshine, and if not kept moist soon gets infested with red spider. Maintain a moist growing atmosphere to assist swelling, damping all portions of the house. Give the trees liberal supplies of tepid water and liquid manure or a surface-dressing of a quick-acting fertiliser before watering. Close early in the day, syringe, and raise the temperature from 5° to 10° higher than the temperature given in the calendar a month ago.

**SUCCESSION HOUSES.**—These trees will now be in full flower and will set freely without much artificial fertilisation if due attention be paid to a free circulation of air, as in country districts bees are often busy during the early part of the day. Should there be any doubts regarding the flowers setting freely, run over the flowers with a rabbit or hare's tail tied to a short stick. Distribute the pollen about midday, as there is abundance of pollen on many varieties, some of the newer kinds, American introductions especially, not being such good setters as older kinds, and in their case it is not well to trust again to tapping the trees or even by insect-fertilisation. Much can be done to strengthen the bloom and maintain a healthy atmosphere by damping all parts of the house, reducing the moisture towards evening. Give air during the flowering stage on all favourable occasions both at the front and top, with a steady warmth in the pipes to keep up the desired temperature should the weather be changeable. The day temperature may be 60° with a drop of 7° to 10° at night; indeed, 50° even now will be a safe temperature in cold or windy weather, as Peaches require ample time at the start to ensure short-jointed wood and a free set.

**LATE HOUSES.**—These trees are far less forward than usual owing to the long-protracted frost, but with increased sun-heat will soon be on the move. Give all the air possible and fumigate such trees in succession for three evenings to get rid of fly. When the shoots are growing freely encourage growth, as there is no gain in retarding at this stage; by so doing growth is weakened. Syringe every morning if the weather be suitable, and as these trees show such a profusion of flower buds the advice given for earlier trees may be practised with advantage, and there will be no fear of bad setting. A light shaking will set the flowers with a free circulation of air. Before the flowering period give the borders a thorough soaking with rain water, which can often be better spared now than later. Should there be any doubts as to dryness, repeat the watering in a few days. Many crops are scanty through dryness at the roots. Doubtless in many cases the surface is moist, but lower down the earth is so much dried that moisture cannot penetrate it. Watering is always best done before the trees are in flower and again when the fruits are all set. To encourage growth from the time the trees are in bloom treat as advised for succession fruits by giving a day temperature of 55° with 10° lower at night. Begin to disbud as early as possible and ventilate freely in fine weather.

**HARDY FRUITS.—PEACHES AND NECTARINES.**—The trees are later this season than usual on open walls, but from this date the sun becomes more powerful. It is not well to delay pruning any longer, and with autumn-planted trees nailing in may be finished. Make the soil firm after the

frost and let the surface soil have a mulch later on, or moisture if required. I do not advise nailing of the shoots of the older or permanent trees till the last moment, as if these trees have been detached from the wall all the winter, by leaving the work to the last moment, growth is retarded and there is less need of covering with thick covers. Remove long naked branches, so as to lay in new fruiting wood, and open the upper portion of the trees as much as possible by lowering some of the stronger branches. It is not well to have all the fruit at the top or crowded; shorten the strong fruiting shoots to about two-thirds of their original length, cutting to a wood bud, and cut away weak or poor wood before nailing to give the fruiting wood all the space.

**PLANTING AND PROTECTING.**—There is little danger in planting now if the work be done quickly, and no lack of moisture both at roots and tops later on. We see how well these trees thrive in nurseries when lifted late. Too vigorous trees which do not fruit well may be lifted with a ball and replanted without fear of injury, thus saving the excessive pruning often necessary, which causes canker and in time total collapse of the trees. Though this work be much better done late in September or early in October when in full leaf, rather than lose a season it may be done now. Protecting must soon be considered, as birds are often troublesome in many gardens. Where they attack the trees, early covering is desirable. There is nothing better for this purpose than a square mesh net doubled or trebled, allowing the net to hang loosely, but quite clear of the tree. Strongly-made nets are even better than any other protection, as it preserves the bloom from frost and birds, at the same time admitting air freely. If birds are not troublesome, leave the covering till the latest moment possible, that is, when the flowers appear.

G. WYTHES.

## ORCHIDS.

### TRICHOCENTRUMS.

Of this genus there are upwards of a dozen species, many of which, however, are only to be met with in establishments where botanical plants are cultivated, whilst a few are really very beautiful flowers worthy a place in every collection. The genus was established some sixty years ago upon a species which up to the present time has not yet been introduced into cultivation. These plants are all natives of tropical America, and are very nearly allied to *Compantias*, which they very much resemble. They are dwarf-growing, epiphytal Orchids, quite destitute of pseudo-bulbs, and therefore require to be kept in a moist condition the whole year round, much less water, however, being requisite during the winter months than in the growing season. These plants in their native habitat grow mostly upon the branches of trees in shady positions, and under cultivation the best results have been obtained by placing them on blocks of wood or in shallow pans, the few kinds here mentioned producing flowers very freely when given this treatment and their other little wants carefully attended to. Sphagnum Moss is the only material that is needed when grown upon blocks, but for those which are placed in pans a little fibrous peat may be added. They are plants that require only a small amount of compost around their roots, and, as before mentioned, must be constantly kept in a moist condition. A moderately cool temperature will be found to suit them best, as at the cool end of the Cattleya house, and as the blooms are of fairly good substance, will continue in beauty for some time if not sprinkled with water from the syringe. Amongst

those most generally cultivated are the following handsome kinds :—

**T. ALBO-PURPUREUM** does not exceed 4 inches or 5 inches in height, the leaves being oblong, very fleshy, and bright glossy green. This kind was introduced about thirty years ago from Brazil and is one of the best kinds we have, producing beautiful blooms which measure nearly 2 inches in diameter. These are borne upon short peduncles singly and sometimes in pairs. The sepals and petals are similar, of a cinnamon-brown colour and tawny yellow on the outer surface; the lip is large, with a wide claw, white, spotted on each side with a purple blotch, and of a yellowish shade on the crest, the stout spur being also white.

**T. MACULATUM**.—This is a native of Colombia, where it grows at upwards of 5000 feet altitude, and although the individual blooms are not so large as in the previously mentioned kind, it is still a very desirable species with white flowers, which are spotted with reddish-crimson.

**T. ORTHOPLECTRUM**.—A very fine and handsome species, which first appeared in this country just twelve years ago. The flowers are large, with deep brown sepals and petals, tipped with yellow, the pure white lip having a blotch of bright crimson-lake on each side.

**T. PEARL**.—This is a very elegant little plant, with acute and clustered leaves, and growing to a height of about 4 inches. It usually produces two blooms upon a spike, which are pure white, marked with chestnut-red at the base. It comes from Central America.

**T. PORPHYRIO**.—A very showy kind, with large flowers, the sepals and petals being soft brown, bordered with yellow, and the lip magenta-purple, having a small white border and a yellow spot on the disc.

**T. TIGRINUM**.—This is a beautiful addition to the family, being a stronger grower, with larger and broader leaves. The flowers are also of fine substance, the sepals and petals light yellow, dotted with red, and the lip, which is large, is white, blotched with brownish-purple and suffused with yellow on the disc.

WM. HUGH GOWER.

**Restrepia elegans**.—The members of the genus to which this charming little plant belongs are allied to the *Masdevallias*. *R. elegans* is one of the best in the genus and a most interesting Orchid. It grows in tufts of little roundish stems about 3 inches high; these are scaly, and each bears a single dark green elliptical leaf. From the axils of these proceed the flower-scapes, each bearing usually a single flower. These are peculiarly constructed, the top sepals long and narrow, broader at the base, the lower sepals united; the petals are narrow, and stand out from the rest of the flower. The ground colour is chiefly yellow, streaked and spotted with crimson and purple. *R. elegans* was discovered by Dr. Korsten growing in cool, moist and shady woods at an elevation of 6000 feet in Caracacas. It thrives under cultivation in the cool house, and may be grown in well-drained pots in peat fibre and Sphagnum. It must not be dried at any time, less water being, of course, required during winter. The species was introduced to this country in 1850, but was grown on the Continent for some time previous to that date.—G.

**Odontoglossum maculatum**.—This is among the most useful of winter and early spring-flowering Orchids, easily grown, constant in flowering, and lasts a very long time in perfection. This, moreover, does not distress the plants to any appreciable extent, provided they are well established, strong, and well supplied with water at the roots. It makes an attractive plant when well grown and flowered; the pseudo-bulbs are oblong, about 3 inches high, bearing several broad, arching, light green leaves. The flower-spikes are produced from the base of these, and bear about six or eight flowers. The inside of the sepals and petals is rich nut brown, transversely barred with green and purple, and the latter thickly

spotted with reddish brown. The lip is yellow, roundish in front, wavy on the edge, with bright red spots. *O. maculatum* likes a slightly higher temperature than *O. crispum* and its allies, but if this is not at command, may be very well grown in the same house. It should be potted in peat fibre, chopped Sphagnum, and broken crocks, given good drainage, and elevated a little above the rims of the pots. The plants require no resting period. Before the flowers are past they commence to grow from the base of the pseudo-bulbs, and this is perhaps the best time to repot, disturbing the roots as little as possible. This Orchid perhaps more than any other in the genus is liable to the attacks of a soft brown scale. This is, however, very easily removed, and with ordinary care will not give much trouble. *O. maculatum* is an old plant in collections, being introduced from Mexico in 1838, where it is said to be very plentiful. It varies considerably in colour, some forms being much richer than others, but all are well worth a place in every collection.—G.

### CULTURE OF ODONTOGLOSSUMS.

THE remarkable degree of popularity to which the members of this fine genus have attained is a sufficient proof of their adaptability to cultivation and their great value as flowering plants. Probably no other large genus contains so few kinds that are difficult of cultivation; in fact there is hardly a species that, if grown in a suitable temperature, with ordinary care will not do well. The practice of keeping these Orchids in a high and moist atmosphere is happily becoming practically obsolete, the danger in the present day tending in the opposite direction, at least as far as the winter temperature is concerned. From a somewhat lengthened experience with these plants, I am convinced that although during the summer months it is hardly possible to keep such as *O. crispum*, *O. Pescatorei*, and *O. triumphans* too cool, yet a minimum temperature of 48° is quite low enough during the winter. Many of the species are very restless Orchids, *O. Halli*, for instance, frequently starting again into new growth as soon as the pseudo-bulbs are finished, yet flowering freely from each set of growths, the roots, too, being nearly always active. This being the case, it is evident that no lengthened period of rest is necessary, although for obvious reasons there must be a slight difference in the summer and winter temperature. *Odontoglossums* are truly alpine plants, and a constant and regular circulation of air must always be kept up in the structure in which they are growing. During the summer months the leaves may be absolutely blown about and kept almost constantly in motion by the wind, and they will be all the better for it, providing the atmosphere is kept well charged with moisture and the plants never get dry at the roots. This will give the pseudo-bulbs that bronzed or russetty appearance that all experienced growers delight in, the foliage also standing erect, stiff and springy to the touch. Plants of this description cannot fail to flower freely at the proper season without any drying off or other unnatural proceedings. A mistake frequently made with *Odontoglossums* is giving them too great a thickness of compost, this, too, occasionally being close and heavy with little or nothing to lighten it in any way, such as charcoal or potsherds, for the roots to cling to. A suitable mixture for these plants will be equal parts of peat fibre and Sphagnum, the crocks and charcoal being better added as the work proceeds. For medium-sized plants the pots should be filled to within an inch of the rims with crocks, leaving less or more in proportion for smaller or larger sizes, and this thickness of compost will be ample to steady the plants in position and to sustain their growth. The old compost should be removed carefully from about the roots, using a pointed stick between and around the pseudo-bulbs where there is not room to introduce the finger and thumb. This done and any decayed roots cut away, wrap a little Moss round those

remaining, place the plants in position so that the base of the leading pseudo-bulbs will be just clear of the compost when finished. Having plenty of finely broken crocks at hand, place a good sprinkling around the Moss and fill up with the compost firmly and neatly to the usual convex mound. Trim off all ragged ends and dibble in a few points of Sphagnum, as these are of great assistance in determining whether or not a plant is dry at the roots. After potting keep the plants rather on the dry side until the roots are seen to be again on the move, when gradually increase the supply as growth proceeds. On fine summer days the syringe must be freely plied among the pots to cause a moist atmosphere, and the plants bedewed overhead twice or thrice daily. A dense shade will be necessary during this period to keep the temperature as low as possible, not limiting this to any stated figure, but always maintaining a pleasantly cool, moist and airy atmosphere, such as feels refreshing on entering on a summer's day from the external air. With lean-to houses or pits having a north aspect this is comparatively easy, but on higher span-roofed structures it is far more difficult. In addition to the ordinary blinds it will often be found necessary to lay garden mats, previously well wetted, over the glass and to keep these moist by syringing. In houses of this latter description it is better to ventilate very freely on summer nights and to keep closer and heavily shaded during the daytime, otherwise it is impossible to keep the atmosphere sufficiently moist. Thus it will be seen that there is practically nothing to hinder the merest tyro from taking up the culture of this section, and as it undoubtedly contains some of the choicest and most beautiful species in the whole Orchid family, he will not be likely to lament his choice. H. R.

**Hybrid Cypripediums.**—In a recent issue you give *C. maculosum* as shown by me at the last meeting of the Royal Horticultural Society. When before the Orchid committee it was identified as *pavonianum*, raised by Mr. Drewett. I therefore wish to withdraw the name I gave it in ignorance of this fact.—F. M. BURTON, *Higfield, Gainsborough.*

**Cypripedium Boxalli.**—A very nice form of this species comes from Cheltenham, which has the dorsal sepal well spotted with very dark spots and the border very distinctly margined with white, the petals being of fine colour and the lip well formed. This plant was discovered by the well-known collector whose name it bears upwards of twenty years ago. It is by some authorities considered a variety of *C. villosum*.—W. H. G.

**Dendrobiums at Cheltenham.**—Amongst the fine Orchids cultivated by Mr. Cypher at his nurseries in Cheltenham are some beautiful kinds now in bloom, *D. nobile* and *D. Wardenianum* being represented in quantity, but of the rarer kinds there are also a large number. Of the last-named, the white variety, *D. Wardenianum album*, is decidedly worthy of notice, the flowers being of the purest white, excepting a small stain of pale yellow in the throat and two very small spots of light brown at the base. *D. crassinode* is also a good species, which flowers profusely at the present season; it is a very distinct plant even when not in flower. The blooms of this kind are produced in twos and threes from the swollen nodes at the upper portion of the stems, and are white, heavily tipped with mauve-purple on each segment: the lip is finely fringed, and has also a large blotch of mauve-purple at the base, a white zone running between the yellow disc and the purple tip. Amongst the hybrid kinds, *D. Leechianum* is one of the finest, being very conspicuous by its large bold flowers; the sepals and petals vary in different forms, from pure white tipped with purple to deep rose, also purple at the ends; the lip has a very downy appearance, is white, with a large blotch of deep rosy-purple at the base, from which run radiating lines of the same shade. *D. endocharis* is another

hybrid, having for its parents *D. japonicum* and *D. aureum* (this last is also one parent to *D. Leechianum*, *D. nobile* being the other). The pure white flowers of this kind are very chaste and beautiful, and, moreover, have a very pleasant fragrance.—W. H. S.

## ORCHARD AND FRUIT GARDEN.

### GOOD APRICOTS.

In many gardens the Apricot, no matter what variety be grown, is disappointing, the branches dying off. Some varieties are less subject to disease than others, and it is the best kinds which suffer most, such as Moorpark. Over-dryness at the roots does far more injury than frosts, and is often the cause of unfruitfulness and decay of the branches. The variety illustrated is less subject to disease, and it is valuable as a bush kind, this being the only Apricot that succeeds well in favoured localities, though there is a Continental variety, the *Alberge de Montgamet*, which is very hardy

*Apricot Breda.* From a photograph sent by Mr. Norman Blake, Bedford.

and can be grown as a standard. In my opinion, however, it is not equal in quality to *Breda*, which it much resembles. Both kinds are especially good for preserving. Of course soils and localities have much to do with successful culture, and a very hot summer is not the best for the trees in a light, poor soil, as we lost more branches after the hot summer of 1893 than in any other period in spite of careful watering. I well remember when a boy many cottagers having splendid trees on the gable ends of their cottages. The fruits were a source of income, helping to pay the rent. The trees were pruned very little, and to this latter cause I attribute much of their success or fruitfulness. Those who like Apricots would do well to grow them under glass, and, as is well known, there have been many failures to force when treated in the same way as other fruits. Many have tried pot culture in orchard houses, but this is not successful. In cold heavy soils with glass one can get reliable crops. For years these fruits should have glass protection much in the same way as orchard house trees, the only difference being that the trees are planted out and a large quantity

of the glass is removed after the fruits are gathered. Some good houses have only a glass roof, which checks frosts and prevents late growth by autumnal rains. The latter are often the cause of loss of branches. During growth the trees require unlimited supplies of moisture, but I would, if possible, limit the amount after growth is completed. With glass protection—the sides of the house being movable to admit air freely—splendid results are secured. Bush trees are best, allowing a short leg or stem of 18 inches clear of the soil. It is not necessary to use fire-heat, my preference for bush trees being that one can allow freedom of growth. There is little pruning if due attention be paid to stopping early in the growing season and the formation of fruit spurs. Trees under glass do not suffer from loss of branches as in the open, and if a gross growth results, lift the trees early in the autumn before the leaves turn colour. Glass copings or cases are of great use in the culture of these fruits, and if the former they should be movable, so as to admit rains at certain seasons of the year. Of course, with cases it is necessary to grow trained trees at the back of the wall, and I would advise what is termed half standards or trees grafted or budded on sufficient length of stem for the upper portion of the trees to be near the roof and in such a position as to get abundance of air.

Apricots blooming so early are the first fruits to require protection, and they do not like badly drained or clay soil. If a good depth of loam and such aids as charred refuse, wood ashes and mortar rubble can be given, I prefer to give manures on the surface in preference to mixing in the soil, as what is wanted is a sturdy growth with abundance of fruit spurs. This latter may be accomplished by using the knife early in the summer, by pinching or stopping, thus having little pruning to do when the trees are leafless. Gumming follows winter pruning if the trees are left to take their chance in the summer. Few fruits pay better for lifting to prevent undue luxuriance, and many trees suffer through having their roots buried too deeply. This can be remedied by lifting, and I would advise lifting young trees every three or four years, placing the roots nearer the surface and giving unlimited supplies of water and liquid manure during the growing season.

I have lifted trees twenty years old, and got fine crops of fruit when such trees have been on a bad aspect. In such cases lift before the leaves change colour and thoroughly water the roots. Syringe the tops daily after lifting till the leaves change or drop. In favoured localities the variety *Breda* does well in bush or standard form, but in most cases these fruits will repay for wall shelter.

As regards varieties, Moorpark is the best in quality, but it is not the most free cropping. The trees gum badly and limbs die wholesale. The fruit is handsome, of a brownish-orange colour, and where the Apricot thrives this variety should be grown, as the fruits are richer than others; in fact, it is a good early dessert fruit. For usefulness I give first place to *Hemskirk*, which grows more freely than Moorpark, does not die off so badly, and possesses what may be termed a better constitution. If only a small space can be devoted to Apricots, this kind should be one of the varieties selected. The fruit is large and of good quality. My next selection is *Breda*, which is invaluable for preserves or compotes in a dried state, but is

less juicy than those named. It is the hardiest of all the varieties, and, as stated previously, is the best for growing in the open in bush form. It may be termed a mid-season kind, and is mostly grown for the purpose named. Large Early is a valuable fruit, and should be selected by those who cannot grow the Moorpark or delicate kinds. I have grown this in cold or exposed positions when all others failed, the tree being of vigorous growth, very prolific, and the fruits large, of a rich orange colour, and very early. I always plant this variety, as it rarely fails to crop if the trees be allowed to extend freely and are not much pruned in their early stages. Royal is a similar fruit as regards growth, succeeding well in adverse soils, but not equal in flavour to Large Early. Shipley is well worth a trial. It is also known under the name of Blenheim, and is earlier than the old Moorpark, being a good preserving variety. The Peach is a very large fruit, rich and of free growth. It much resembles Moorpark in flavour; and Kaisha completes the list. The last is not a large fruit, but early and of rich flavour, and the trees crop freely. There are nearly twenty other varieties, but the few named I consider are the best.

G. WYTHES.

**Peach Dymond.**—Although I have known this variety for many years, I have not observed any susceptibility to the attack of aphides as mentioned by "W. S." (p. 94). There is something curious about the manner in which certain varieties are prone to attack in some gardens and not in others—as, for instance, Pine-apple Nectarine in a former situation was always infested with black aphid in the spring, no other variety being attacked, and which I have never seen in any other garden where the Pine-apple was grown.—W. G. C.

**Protecting tree stems from ground game.**—I have nowhere seen a simpler or better method of protecting the stems of standard trees from hares and rabbits than was adopted by the late Mr. J. James in his orchard at Farnham Royal when he planted it several years since. Wire mesh of some 2 feet broad was cut into short lengths and fastened securely, yet loosely round the stems without at all burying or fixing the wire. When rabbits come in contact with the wire the motion created serves to alarm them because so incomprehensible, and they keep away. The orchard in question covered some five or six acres of Grass land close to Burnham Beeches, and was almost surrounded by rabbit and hare infested woods, yet the immunity from injury was remarkable. Of course, this form of treatment could hardly be applied in the case of dwarf or bush trees. Then there is no safer method than in fixing a wire fence all round the orchard. Such wire fencing should be firstly of 3 feet depth, some 4 inches of the lower side being not only buried in the soil, but also held there by iron pegs. With even such fences rabbits are sometimes tempted to burrow deep and thus go under, for the severely fixed wire fence does not alarm them. Then if the fence be rather low they can easily leap over it. In these days of good market prices it is surprising that such pests as rabbits should be so much tolerated, yet there are millions in the country doing immense harm, whilst myriads of persons would be only too glad to purchase them for consumption at reasonable prices.—A. D.

**Lifting Vine roots.**—Many gardeners do not seem to be aware of the benefit which almost invariably follows the lifting of the roots of old Vines, providing the latter are not altogether worn out. From various causes, not the least being excessive top-dressings, Vine roots are often driven downwards in search of nourishment, and being then too far from the influence of sunlight and air, degenerate into fibreless thongs, inferior crops and shanked berries following in due course.

Such Vines are often condemned and rooted out, new borders being made and young Vines planted, but this expense might often be spared and better results obtained by carefully removing the soil, lifting and carefully preserving the roots, rectifying the drainage if necessary, and after incorporating some good sweet loam with a portion of the original soil, adding more rubble and some horse manure, relaying the roots on a firm bottom some 6 inches from the surface, and after cutting back any decayed or useless ends and freely notching the remainder, covering them first with an inch of extra sharp sandy soil, and finally with 5 inches of the ordinary soil. Many old Vines treated in this way yield far better crops of Grapes than they did when considered to be in their prime, or, say, the first ten years after planting. The work should be done when the foliage is changing colour, so that new rootlets may be formed even before the Vines go to rest. If needs be, Hamburgs may be forced early the following season, but it is always well where practicable to start the house a month later to give the Vines the best possible chance. Some Vines so treated last autumn have this year broken from a fortnight to three weeks earlier than for many years previous, and growth looks strong and healthy. Of course, if when the roots are lifted all new soil can be spared, so much the better.—J. C.

**Disbudding Peaches.**—In reading the article on disbudding Peaches on p. 25, I could not but notice the remarks of "W. G. C.," who says that he always does disbudding of Peaches himself. I think there are many young readers like myself who will be disagreeably surprised to hear that foremen are incapable of doing that work, and should say "W. G. C.'s" place is not a large establishment if he disbuds entirely himself. In places where there are three or four Peach houses and perhaps 200 yards of Peach casing, the gardener would have many other duties to attend to other than Peach-disbudding. What a blow to all foremen aspiring to the position of head gardener to hear that they are deficient in that branch of gardening, also to know, if they are lucky in getting into a good place, that they cannot depend upon a foreman. What are they to do then? Must they ask advice from older hands? In my opinion, in many of our finest gardens the Peaches are under the management of foremen trained by their former masters. There are very many painstaking and energetic young men at the present time who no doubt can (and are) depended upon to do satisfactorily the by no means hard task of disbudding Peaches.—FOREMAN.

**Apple Loddington Seedling.**—The note on this kitchen Apple (p. 111) by "S. H." only serves to show more plainly that while a certain variety behaves in the best possible manner in one district, in another its success is reduced almost to a minimum. Nowhere have I seen this Apple (which is more often known under the name of Stone's, owing to the fact of the original tree being found on Mr. Stone's farm at Loddington, in Kent) giving such good results as at Barham Court, where Mr. Woodward finds that it flourishes remarkably well in loamy, porous soil of good depth. Here in our heavier retentive soil the branches show a disposition to canker, and at no time since planted have our trees given even a fair crop.—E. M.

**Cherry St. Margaret.**—Most of the best fruits receive so many synonyms that it is difficult for those with only a slight knowledge of varieties to judge or understand why the kind named St. Margaret should be called Black Heart, Large Black Bigarreau, Elkhorn, and Tradescant's Heart, the names also being changed in some places to that of the locality. Despite this drawback, the above variety is a grand fruit, and one of the most useful late varieties we have. It is a large black fruit, very late, and well adapted for wall or cool house culture. In the latter it is splendid, and being protected from moisture and birds is very fine for dessert. The flesh is sweet with a brisk flavour and the tree is very free. I do not recommend it for bush or

pyramid form in the open, as it is difficult to keep free of birds, but it is well worth wall culture, the trees being well supplied with moisture in the shape of liquid manure or a mulch of decayed manure to keep the surface roots active. Being later than many of the dessert Cherries, it is worth planting in every garden where good dessert fruits are wanted in quantity and of the best quality.—G. WYTHES.

**Apple Gascoigne's Scarlet Seedling.**—From the growth made by trees in the garden here the last three years it appears to me that this Apple will require much space to get good results. Where space is limited, root-pruning must be practised vigorously to induce fruitfulness. In Kent, where this Apple is remarkably well grown, the trees have abundance of room to develop their branches without root-pruning, the consequence being fine crops of well-coloured fruit, which cannot fail to find a ready market. Not only is this Apple showy, but the quality is such as to place it in the first rank as a kitchen or dessert fruit during the early part of the winter months.—E. M., *Hants.*

**Apple Devonshire Quarrenden.**—This Apple is much grown here in cottage gardens. So well does it succeed, that many of the cottagers make the most of their rent from a few old standard trees. The fruit always commands a ready sale at 7s. 6d. per bushel. It is the first dessert Apple ready for use in quantity in this part. In some gardens where the soil is inclined to be heavy and retentive of moisture the trees are liable to canker and become thickly infested with Moss and Lichen, which check their free growth. Where the soil is loamy and fairly dry this Apple succeeds admirably. Two years since I counted 130 full-sized fruits on one branch a yard long.—E. M., *Bishop's Waltham.*

#### APPLES.

THE correspondent on p. 113 who expresses himself as perfectly astounded at any depreciatory remarks levelled at Cox's Orange Pippin must surely be aware of the imperative necessity of taking soil and site, the first named especially, into consideration when Apples are planted, and that in the case of some varieties peculiar conditions render successful culture well-nigh impossible. It is, or should be, the aim of every gardener to find out the sorts that are thoroughly satisfactory and to plant them as much as possible to the exclusion of others, and it is hardly likely that well-known growers will exclude a high-class Apple unless it be found wanting in some respect. I think the remarks made by "A. Y. A." will be welcomed by all those who have found a difficulty in growing the variety above named, Ribston Pippin, Margil, and one or two more. It would be difficult to find a more striking instance of the likes and dislikes of the Ribston in a limited area than is furnished by our cankered trees (which are being gradually worked out) and the magnificent specimens at Pain's Hill, probably about the finest espalier Ribstons in the kingdom, a sight when laden with fruit to gladden the eyes of any fruit tree lover. They are growing in a very old low-lying kitchen garden in rich black soil, apparently of great depth. Cox's certainly does better with me than Ribston, but it cannot be pronounced a success, being below average both in crop and size and the fruit destitute of colour. To speak well of the "bridge that carries one over" is a sound maxim in fruit growing, and for our light sandy soil the best dessert Apples are King of Pippins, Adams' Pearmain, Cornish Aromatic, and Cockle Pippin, great and consistent croppers, and giving fruit of fair average size. Cornish Gilliflower crops fairly well, but unless the trees are netted quite early in the season the fruit is of little use; the blackbird seems perfectly aware of its high quality and makes a persistent attack directly the bush fruits are over. A good word has been said for Mannington's Pearmain. It does very well here, but I should not grow it in preference to the two latest of the four varieties above named.

E. BURRELL.

## FLOWER GARDEN.

## LILIUM LONGIFLORUM HARRISI.

THERE are two widely divergent opinions concerning this Lily, depending upon the standpoint from which it is viewed, for by the botanist it is regarded (and rightly so) as a variety of *L. longiflorum*, while the horticulturist usually considers it a distinct species under the name of *Lilium Harrisii*. It is undoubtedly the most popular Lily in cultivation at the present time, and is grown in immense numbers by all our florists. A striking proof of its popularity is furnished by the fact that it is indeed rare during several months of the year to pass a florist's establishment without seeing its long pure white blossoms exposed for sale either in a cut state or on growing plants in pots. The quantity of this Lily that passes through Covent Garden Market alone during the season must be something enormous. It is now twelve years since *Lilium Harrisii* was sent here from Bermuda, and at that time among the several distinctive features claimed for it was that it flowered so much earlier than *L. longiflorum*, while after blooming, secondary stems were pushed up, which in their turn produced blossoms.

This is strictly true as far as freshly imported bulbs are concerned, but after one season's growth in this country it does not (under the same conditions) flower any or but little earlier than the other members of the longiflorum group, and in another year the difference, if any, totally disappears. Its precocious character is induced by the conditions under which the bulbs have been grown, for not only do they attain a greater vigour in Bermuda than they do with us, but the season is also so much earlier, that we receive thoroughly well ripened bulbs from there before those in this country are out of bloom. The earliest bulbs reach here by the end of July, and in another month they are widely distributed throughout the country. As the bulbs at that time are ready to push forth roots at the base, they should for early flowering at least be potted directly they are received and kept moderately moist till growth commences. A cold frame just to keep off any unusual quantity of rain will suit them well when first potted, or they may be stood out of doors and covered with ashes, as is done in the case of Hyacinths and other bulbs when grown in quantity. If this latter treatment is followed, care must be taken that the covering is removed as soon as the shoots get clear of the soil, otherwise they will be greatly weakened thereby. The protection of a greenhouse will suit this Lily well during the winter, but its cultivation has been so often dwelt upon in THE GARDEN, that nothing more remains to be said on that point, except to call attention to the great damage quickly done by aphides if they are allowed to effect a lodgment on the plants. They first of all attack the young unfolding leaves in the centre of the plant, and unless closely inspected their presence may not be noticed till irreparable injury is done, for the embryo flower-buds are situated there, and a few punctures from these insects will cause the blossoms to be deformed. In speaking above of the great advantages of early potting for those that are needed to bloom first, it is as well to point out that most of the Bermuda bulbs are received here at much the same time, and are kept in their boxes on shelves in dealers' warehouses or similar places not con-

ducive to their welfare, for this, in common with all other Lilies, suffers a good deal if kept dry after the usual season to recommence growth has come round. It is true many will flower if not potted till the end of the year or later, but they are altogether wanting in the vigour of the early potted ones. Thus for later blooming pot fairly early, and keep as cool as is consistent with safety during the winter. Apart from its merits as a pot plant, the Bermuda Lily is also an object of great beauty when grown out of doors, as it will flower beautifully in this way. If the bulbs are planted in the autumn, the young shoots will frequently appear above ground by the winter, when a little loose litter may be sprinkled over for protection, though they may not require it, for I have some that were at the commencement of this year an inch above ground, and not being covered in any way they were frozen for weeks, and as far as one can at present judge, with the exception of a few out-

besides these above-mentioned there are also *Wilsoni*, *eximeum*, *grandiflorum*, *densatum*, *Takesima*, *Mme. von Siebold*, *albo-marginatum*, and *roseo-marginatum*. It must not be supposed that all of the above represent a distinct form, for if grown together for two or three years many of their points of difference will disappear. H. P.

## SELECTED VARIETIES OF CARNATIONS.

THE National Carnation and Picotee Society (Southern Section) have just published their report for the year 1894, showing a balance in the hands of the treasurer of £160. The exhibition for next season will be held in the central transept of the Crystal Palace, and a sum of £150 will be given in prizes, but the most interesting part of the report is the returns from twenty-two members and exhibitors of the society, giving a selected list of varieties. The Carnation and Picotee for purposes of exhibition are divided into thirteen

Group of *Lilium longiflorum Harrisii*. Engraved for THE GARDEN from a photograph sent by Miss Willmott, Warley Place, Great Warley, Essex.

side leaves, they do not seem to have suffered any particular injury. When this Lily was first sent here from Bermuda in quantity there used to be a sprinkling of the typical *L. longiflorum*, but of late years the stock seems to be quite true. The typical kind is in many respects much inferior to the variety *Harrisii*. When attention was first directed to this Lily it was at times sold under two names, *Harrisii* and *floribundum*, but this last seems now to be altogether dropped, and rightly so, as the two were really identical. The specific name of longiflorum conferred upon the type is now somewhat of a misnomer, as in length of bloom it is surpassed not only by its own varieties, but also by *L. neilgherrense* and *L. philippense* as well. *L. longiflorum* is not only shorter in the tube than its variety *Harrisii*, but the flower is more erect, and there are also less blooms on a stem. Large numbers of a variety much like *Harrisii* are sent here from Japan during the winter, but though they will flower well, the bulbs are not nearly so large as the Bermuda-grown ones. Varietal names have been bestowed pretty freely in the case of *L. longiflorum*, as

classes, and it is these divisions and sub-divisions that puzzle the amateur when first attempting the culture of these fine garden flowers, but anyone with the least knowledge of colours can readily distinguish the different classes.

When the "Carnation Manual" was published by the society three years ago similar returns were obtained, and a comparison between the two is interesting. In the classes of flakes and bizarres the best twenty-four varieties are as follows, and the number of votes are given to each: Robert Houlgrave, 17; Robert Lord, 14; Admiral Curzon, 14—same as in 1892. Crimson bizarres: Master Fred, 15; Rifleman, 13; J. D. Hextall, 12. In 1892 Harrison Weir was second, Rifleman first, and Master Fred third. Pink and purple bizarres: William Skirving, 18; Sarah Payne, 17; Harmony, 7. In 1892 Mrs. Barlow occupied the place of Harmony. Purple flakes: James Douglas, 18; Charles Henwood, 17; George Melville, 11. In 1892 Gordon Lewis held the place of Charles Henwood. Scarlet flakes: Sportsman, 18; Alismond, 15; Miss Constance Grahame, 13. Miss Constance Grahame has taken the place of Matador, which has fallen into the fourth place. Rose flakes: Thalia, 16; Rob Roy, 15; Sybil, 11. Thalia stood at the top with 17 in 1892, Sybil next with 16,

Rob Roy 12. The above twenty-four varieties is a selection from seventy-eight, and as they are all well known and cultivated by the fanciers, they may be depended upon to be the best selection obtainable. The best eighteen Picotees come out as under: Heavy red edge: Brunette, 16; John Smith, 16; Ganymede, 15. The last-named is a new one, and has rapidly risen to a high position. It has taken the place of B. Bryant. Light edged red: Thomas William, 18; Mrs. Gorton, 18; Miss Violet Douglas, 16. The same three headed the list in 1892 with 17 votes each. Heavy purple edged: Muriel, 18; Amy Robsart, 15; Zerlina, 14. In 1892 they stood with Mrs. Chancellor second and Amy Robsart in the fourth place. Light purple edged: Ann Lord, 17; Clara Penson, 15; Mary, 13. In 1892 they held the same position. Heavy rose and scarlet: Mrs. Sharpe, 18; Mrs. Payne, 14; Little Phil, 14. Edith D'Ombraïn held the place in 1892 now occupied by Little Phil. Light rose and scarlet edged: Liddington's Favourite, 18; Nellie, 16; Ethel, 11. The same as 1892. The above selection is from sixty-nine varieties. In the yellow ground Picotees the best eighteen varieties are: Mrs. R. Sydenham, 17; Countess of Jersey, 17; Lillian, 14; Agnes Chambers, 13; Annie Douglas, 12; Mrs. Henwood, 12; Mrs. Whitbourn, 10; Almira, 7; Mrs. Douglas, 7; Ladas, 7; Aurora, 6; Mrs. Dranfield, 6; Florrie Henwood, 6; Stadraath Bail, 5; Undine, 5; Mrs. Alfred Tate, 4; Romulus, 4; Chrysolora, 4. The best twenty-four self-coloured varieties are: Hayes' Scarlet, 10; Niphotos, 9; Germania, 9; Waterwitch, 8; King of Crimson, 7; Mrs. Louisa Jameson, 7; Mephisto, 6; Ruby, 6; Miss Audrey Campbell, 5; Miss Ellen Terry, 5; Mrs. R. Hole, 5; King of Scarlets, 5; Mrs. Fred, 5; Emmie, 4; Oriflamme, 3; Kettin Rose, 3; Burn Pink, 3; Lady Gwendoline, 3; Meteor, 3; Duke of Orleans, 3; King Arthur, 3; Eudoxia, 3; Royal Purple, 3; Abigail, 3. Some of the above yellow ground Picotees and self-coloured Carnations will take higher positions when they are better known. Amongst yellow ground varieties, Mrs. Douglas, Ladas, Mrs. Dranfield, Florrie Henwood, Mrs. Alfred Tate, President Carnot, and Mrs. Gooden have not yet been grown by anyone except the raisers of them. It is very remarkable that Hayes' Scarlet in self should go at one bound to the top of the list, but it is evidence of the superior quality of that variety. Niphotos holds a very high position, as coming in second. Other new varieties, as Waterwitch, Mephisto, Miss Audrey Campbell, Miss Ellen Terry, Duke of Orleans, King Arthur, Eudoxia, and Royal Purple, will certainly go up higher when they are grown as border varieties. At present they, like the yellow ground varieties, have been confined to a very restricted area.

J. DOUGLAS.

## BOOKS.

### THE STUDENT'S ENGLISH DICTIONARY.\*

ALTHOUGH not too large for convenient reference, this dictionary seems very complete. A dictionary intended for the use of students, and as such occupying a place midway between a school dictionary and a bulky lexicon, it seems to fulfil its purpose admirably. Although nominally a new edition, its editor claims for it that it is in fact a new work, "since not only have all the old articles been thoroughly revised and to a great extent re-written, but many thousands of additional articles have been inserted." What is a new feature, we think, as regards dictionaries, and a valuable addition to the present work, will be found in the appendices composing a list of names in fiction, mythology, &c., and a key to literary allusions. Thus to take a few familiar instances: Under the head of "Heep," Uriah is summed up as "clerk to Mr. Wickfield, the lawyer, in Dickens's 'David Copperfield,' a sneaking and malignant character,

\* "The Student's English Dictionary." By John Ogilvie, LL.D., being a new edition, revised and greatly augmented by Charles Anandale, M.A., LL.D.

always proclaiming how 'umble he is,' &c., and "Peebles," Peter, in Scott's "Redgauntlet," "a disreputable pauper with a craze for litigation," and so on with more or less detail, the student sees at a glance the main points of a character he perhaps frequently hears mentioned in conversation without being put to the trouble of reading up the character in the original. So also names which frequently occur when old myths and legends are talked about. There are also lists of English authors with dates, a pronouncing list of classical and scriptural names, &c., together with nearly eight hundred engravings on wood: it is printed in clear and readable type, and the price, 7s. 6d., is not by any means exorbitant.

### THE FOREST FLORA OF JAPAN.\*

JAPAN has come in for a good deal of patting on the back of late. It has become the fashion to write books about Japan. In adopting Western forms of government and ideas, at least outwardly, and taking advantage of the most modern inventions and appliances of Western science, she has shown an adaptability all the more remarkable because so contrary to the traditions, the customs and the spirit of Eastern peoples. Her marvellous and unsuspected good fortune in her hostilities with her larger, richer, more populous, but conservative and backward neighbour have won for Japan a host of admirers, some of them even sincere. The present work is only one of many books about Japan we have recently had the pleasure of reviewing, and it is certainly not the least valuable contribution to Japanese literature. Japan's wealth in tree species is perhaps not surpassed by any country of the world. It has been shown that, rich as Eastern America is in the extent and variety of her forest produce, Japan and the regions north of it, in spite of their comparatively small area, are still richer. Many years ago, Professor Asa Gray wrote that in the Japan-Manchurian region he found 168 trees divided among sixty-six genera, and in Eastern America 155 trees in sixty-six genera, the enumeration in both cases being confined "to timber trees or such as attain in the most favourable localities to a size which gives them a clear title to the arboreal rank." Since Professor Gray published the results of his investigations it has been proved that of the trees enumerated a number are not indigenous to Japan, but were brought there long ago from China and Korea, like most of the plants cultivated by the Japanese. "The proportion," says the author in his introduction to the book, "of trees to the whole flora of Japan is remarkable, being about 1 to 10-14, the number of indigenous flowering plants and vascular cryptogams being not far from 2500 species. Still more remarkable is the large proportion of woody plants to the whole flora. In Japan proper there are certainly not less than 325 species of shrubs, or 550 woody plants in all, or one woody plant in every 4-55 of the whole flora—a much larger percentage than occurs in any part of North America." Remoteness, bad roads, and the impossibility of bringing down their timber to the valleys have saved the mountain forests of Japan, which may still be seen, especially between 5000 feet and 8000 feet above the sea level, in their natural condition. These elevated forests are, however, composed of comparatively few species. On the mountain slopes 5000 feet above the sea the Hemlock forms continuous and almost unbroken forests of great extent. An almost impenetrable mass of dwarf Bamboos of several species forms the undergrowth of these forests even high on the mountains and in the north. To this abundance of the Bamboo, making impossible the growth of all except the most vigorous species of under shrubs, the author attributes the climbing habits in many Japanese plants, "which are obliged to ascend the trees in search of sun and light, for the Japanese forest is filled with climbing shrubs, which

\* "The Forest Flora of Japan." By Charles Sprague Sargent, Director of the Arnold Arboretum, of Harvard University. Houghton, Mifflin & Co., Boston and New York.

flourish into tropical luxuriance." The book contains chapters on the Magnolias, the Ternstroemias, Linden and Rues, Holly, Euonymus and Buckthorns, Maples, Sumachs and Pers, the Roses, Witch-Hazel and Aralia, Cornels, Honeysuckles and Persimmons, the Styrax, the arborescent members of the Heath family, the Ashes and their allies, the Laurel, Euphorbia and Nettles, Walnuts, Birches, Alders and Hornbeams, Oaks, Chestnuts, Willows and Poplars, the conifers, and also a chapter on the "economic aspects of the Japanese forests."

As regards the outward appearance of the book, we regret to say that, although from the outside an artistic book, the use of the commonest forms of mechanical processes in the illustrations in lieu of engravings has given the book a very commonplace look unworthy of its author or of the subject. This hard style of reproducing destroys all the value and tone of the cuts and all the charm of distance. The same remark applies to the illustrations of plants, which are not shown in light and shade, but are merely diagrams. Even where the engraving is good the drawing is devoid of light and shade. The book is printed on heavy clay paper instead of the delightful old paper which such books were printed on before the present clay paper. Still we should be grateful for this work of Mr. Sargent, who, by his knowledge and love of the work, is so well fitted for it.

## NOTES OF THE WEEK.

**Great quinquennial bulb show at Haarlem.**—The fifth great quinquennial bulb show will be held by the Royal Bulb Society of Haarlem from March 22 to 26. The competition is open for members of the society only. Most of the leading firms of the famous bulb district will be among the exhibitors.

**Strobilanthes Dyerianus.**—This plant is attractive for winter decoration both in and out of flower, its bright hues of peacock-blue and green foliage being always pleasing. Combined with this it is very free flowering, the flowers being of a darkish blue. It grows very freely and is of easy propagation, and is, I hear, a good bedding plant in America.—W. A. Cook, *Compton Bassett*.

**Orchids from Abergavenny.**—I am sending a few Orchids, comprising *Angraecum Humbloti*, the plant of which has two spikes with two flowers on each, one of which I am sending you; *Cypripedium Chamberlainianum*, a good form of *Dendrobium nobile*, *D. candidissimum*, and *Odontoglossum Roezli album*.—G. C. WILLIAMS, *Trajan House Gardens, Pandy*.

\* \* A nice gathering of flowers. The *Cypripedium* represented an especially good form of the beautiful *A. Chamberlainianum*. The forms of *Dendrobium nobile* were excellent.—Ed.

**Bouvardia Priory Beauty.**—This is, I think, one of the most effective of all the varieties of Bouvardias. It is very handsome and much admired, and with us very popular. Its habit is dwarf and erect, very free flowering, and lasts a long time in flower—longer than any other that I am acquainted with. Cuttings should be struck at once and the plants grown on without check, when well grown plants will commence to flower in October and continue till February.—W. A. Cook, *Compton Bassett, Calne*.

**Salvia pulchella.**—This slender growing, evergreen, pretty shrub is generally described as a greenhouse plant, but it is much more hardy than is generally supposed, as it will stand from 10° to 15° of frost with impunity. It has been growing here for several years trained on a wall with south-east aspect. Last year it made growths 9 feet long and produced its scarlet flowers for five or six months, or until the flower-buds were destroyed by frost. It is easily increased by suckers, which spring up thickly around the base of the plant. A good sandy loam with leaf soil or

peat suits it well. It cannot be too highly recommended for covering walls in warm situations.—W. O., *Fota*.

**Phajus grandifolius.**—This fine old Orchid is excellent for decorations. We recently noticed a nice lot of plants in bloom at Syon House. The value of this Orchid is its long lasting and its freedom of flowering in small pots. In a damp house the flowers soon spot, but if removed to a cool, dry position remain good for weeks. We know of no Orchid better adapted for rooms. We have had plants four or five weeks in a living room, and such plants flower every year. To get it in condition for this purpose feed from the surface in preference to overpotting.

**The frost and shrubs and plants.**—No doubt the editor will shortly be inundated with tales of disaster resulting from the late severe weather. To all who intend writing such lists I earnestly say do not, but, on the contrary, let us have and from all quarters the fullest possible lists of those things which have not been injured. Should we have a series of killing winters, all the beautiful shrubs and trees which are able to bear with impunity the lowest temperatures we are ever likely to have would get a chance in our gardens. Let us try and find out what these are.—T. SMITH.

**Actus gracillima.**—This is a delightful plant and very graceful. It is at Syon House, Brentford, in a very cool house, with such things as require little heat, and the plants are in rather small pots, the growths being covered with the yellow and crimson Pea-shaped flowers. The flowers are very small, but there are few plants which bloom more freely and are more readily grown. If kept well cut back after flowering, a bushy growth is encouraged, otherwise it is inclined to become naked at the base. The plant does not like overpotting, and good specimens may be grown in small pots. Cuttings of the half-ripened wood strike freely in May under a bell-glass in sandy compost, and the young plants do well grown in cold frames through the summer.

**Persian Cyclamens at Syon House.**—During the past two months these have been remarkably fine here, a light greenhouse being devoted to them. Mr. Wythes relies chiefly upon young plants, as he obtains finer blooms. I notice that the majority are in  $\frac{1}{2}$ -inch pots, and the varieties with white flowers are delightful. The culture of Cyclamens is simple, the plants being grown in large batches for winter bloom. The seed is sown as soon as ripe, so that the plants when they begin to flower are about fifteen months old. They are grown in frames all the summer on a hard coal-ash bottom, and removed into flowering quarters in November. The seedlings are kept on the move from the start. They are not dried off, and the same remarks apply to older plants, as these never lose all their old leaves when resting.—VISITOR.

**Mossy lawns (E. W. B.).**—One cause of the bad condition of the lawn is undoubtedly bad drainage. If the soil is light loam or chalk, the soil being very wet in winter and much burnt up in hot, dry weather, the remedy is not merely drainage, but food in the spring to enable the Grass to get more roothold and resist drought. If the land is wet, take up the turf and lay drains at about 9 feet apart, 1 foot deep, and use 3-inch drain pipes. Give a fall to the lowest portion of the lawn if possible. Make a good basin 3 feet to 4 feet deep at the lowest end. Fill in with rough brick rubble. This will take away the surface water, and it is well to also cover the drain tiles with rubble, clinkers, or rough ashes. Before replacing the soil, allow 3 inches to 6 inches of soil over the rubble for the turf to rest on. If you do not drain, you must give new surface soil. Rake away any Moss as deep as possible with an iron long-toothed rake, and give a surface-dressing of new loam and manure. Make firm and sow seed at once, covering the latter with fine soil. The quickest way is to re-turf, but before so doing the soil must be well drained. Wood ashes or burnt garden refuse of any kind mixed

with bone-meal is the best fertiliser for Grass land, as the ashes kill the Moss and the bone-meal encourages rapid growth. This is much better than applying lime to a chalky soil. I have renovated such land as yours by raking away the Moss, sowing a fine mixture of Grass and Clover, and using the above soil freely. It is also well to dress such land every season early in the year to promote a close growth.—G. W. S.

## OBITUARY.

### MR. THOMAS BAINES.

We regret to announce the death of Mr. Thomas Baines, which took place last Saturday at Palmer's Green from influenza and pneumonia. Among the best gardeners few, if any, were better known than Thomas Baines, who first distinguished himself as a plant grower, perhaps the best grower of our time. Afterwards he became an author and also designer of gardens. So far as we can judge in our own time, there never was a better plant grower than Thomas Baines, as tested both by the northern shows and those about London. There are people who think that to write is characteristic of the non-practical man, but such an opinion was not justified by the case of Thomas Baines, because he was a voluminous writer for the garden press and wrote an excellent book on stove and greenhouse plants, which is indeed the standard work on a subject he knew so well. He was extensively engaged in laying out gardens, and amongst other large places which he planned, or greatly altered, were Glansvern, Montgomeryshire; Cloughton-on-Brock, near Preston; Waddesden, Chacombe, Banbury, Broxbournebury, Boxley and Munden Park, Herts; besides many minor places. Mr. Thomas Baines was a Lancashire man, his people having been stewards and gardeners among the old estates there for many generations. He was seventy-two years of age, and was buried on Thursday last in the Great Northern Cemetery, Old Southgate.

**Mr. Joseph Lakin.**—We regret to hear of the death of this well-known authority upon florists' flowers, especially Tulips. His death took place at Temple Cowley, near Oxford, on Monday last at the age of sixty-seven.

**The late Alderman Sir Francis Wyatt Truscott.**—The death of this prominent citizen of London severs another tie, so to say, binding the International Horticultural Exhibition of 1886 with the present day. The Corporation of the City of London, when granting the use of the Guildhall for the purposes of the banquet to the more eminent foreign visitors invited to take part in the exhibition and botanical congress in connection with it, appointed six of its members to assist in the arrangements of the banquet, viz., Mr. Deputy Charles Reed, afterwards Sir Charles Reed, Mr. Deputy Obbard, and Messrs. J. E. Saunders, J. Kelday, F. Wyatt Truscott, and W. Lawley. Of these six, I think only Mr. W. Lawley survives. Sir F. W. Truscott was a particularly active helper, and materially assisted in making the banquet a success, which was presided over by the late Alderman Sir B. Phillips, then Lord Mayor of London.—R. DEAN.

**Mr. R. B. Laird.**—We regret to hear that the death occurred on Monday, from heart disease, of Mr. R. B. Laird, senior partner of the firm of Messrs. R. B. Laird and Sons, nurserymen, Edinburgh, and W. P. Laird and Sinclair, Dundee. He was born at Balgone, North Berwick, in 1823, and went at an early age to Dundee, and worked under his elder brother, the late Mr. W. P. Laird. He came to Edinburgh in 1843, and was about five years in the establishment of Messrs. Dickson

and Co. In 1848, with the late Mr. John Downie, he founded the business in Frederick Street, and lately at West Coates, which was well known for many years as Downie and Laird. At the dissolution of this partnership the firm was carried on under another designation by himself and his sons, and latterly he had been for the most part resident in Dundee, where another branch was established. Mr. Laird was widely known, and was one of the remaining links between the past and present generation of horticulturists. By many gardeners, old and young, he will not soon be forgotten. He was always ready to lend a helping hand to those in need of assistance, and he spent much time in doing what he could to further the interests of young gardeners, and to get them a start in life.

We are informed that Mr. William Serymgeour, of Shrubland Park, near Ipswich, forester to Lord de Saumarez, and late forester to Sir Herbert Maxwell, M.P., Monreith, Wigtonshire, N.B., has been appointed a government forester in the Forest of Dean, and will commence his duties there in the beginning of March.

**The weather in West Herts.**—A cold week and the sixth in succession. It had in it, however, one mild day, March 1, this being the first day since January 21, when the weather has been the least unseasonably warm. In fact, since the beginning of the year there have been as yet only nine days when the mean temperature has been above the average for the season. The ground is still very cold and in shaded places remains frost-bound. In an open spot fully exposed to the sun where my underground thermometers are situated the temperature at 2 feet and at 1 foot deep is the same, and now stands  $2\frac{1}{2}$  above the freezing point. During the twenty-six days ending the 3rd inst., the soil in the same open spot at 1 foot deep remained at or below freezing. A little snow fell on the first four days of the month, and on the 2nd and 3rd sufficient was deposited to completely cover the ground.—E. M., *Berkhamsted*.

**Isle of Thanet Chrysanthemum Society.**—The annual show of the above society will take place at the Hall by the Sea, Margate, on November 13 and 14.

**United Horticultural and Benefit Society.**—The annual meeting of this society will take place at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday, March 11, at 8 p.m. Mr. Geo. Gordon will preside.

**Royal Horticultural Society.**—The next meeting of the R.H.S. will be held on Tuesday, March 12, in the Drill Hall, James Street, Westminster. Special prizes are offered for Daffodils, and at 3 p.m. a paper by Mr. Collette, of Guernsey, on the "Diseases of Potatoes," will be read.

**Gardeners' Royal Benevolent Institution.**—The Duke of Fife, K.T., P.C., has kindly consented to preside at the fifty-sixth annual festival dinner in aid of the funds of the Gardeners' Royal Benevolent Institution at the Hôtel Métropole on June 23 next.

*Garden Sketches.*—Mrs. Kingsley, South of Ireland

**Names of plants.**—G. Sharratt.—The bloom sent is a small, but nicely coloured form of *O. tripudians*, and though a useful free-flowering kind, is certainly not superior to *O. triumphans*, which compares favourably with any of the yellow-flowered section of the genus. *O. tripudians* is a native of New Grenada, and is found at a great elevation, so that it thrives well under the coolest treatment.—*Inquirer*.—*Crassula lactea*. Cuttings strike root freely in greenhouse in light soil.—J. Russell.—1, *Salvia coccinea*; 2, *Jasminum gracillimum*; 3, *Pelargonium Pretty Polly*; 4, *Echeveria retusa*.

**The Wild Garden:** or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers. Fourth edition, with wood engravings from drawings by Alfred Parsons, revised and enlarged. Demy 8vo, linen cloth. Price 12s.; well bound in half morocco, 18s. Through all booksellers.

No. 1217. SATURDAY, March 16, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHIDS.

## NOTES ON CATTLEYAS.

IN such an important and widely distributed genus as *Cattleya* it is not surprising that varying modes of treatment, as regards temperature and other details, are necessary to their successful culture. The season for repotting many kinds being at hand affords growers an opportunity of noticing what progress the roots have made, and whether the compost provided for them is suitable or the reverse. It is unfortunately often found that these have been seeking the outside of the pot, while in the compost there is hardly a root deeper than an inch below the surface. In such a case it is clear that the rooting medium has been too close and heavy, possibly in too great bulk, and lacking hard, incompressible substances for the roots to cling to and for aerating the compost. The use of sand in the potting material has also much to answer for with regard to this state of affairs, and whenever I have had occasion to repot Orchids of this class where this material has been used, I have invariably found the roots more or less decayed owing to it. Strong-growing and rooting species, as *C. Mossie* and *C. Trianae*, may force a few roots into a compost of this description, but if long subjected to such treatment the health of the plants would certainly be impaired, while *C. Walkeriana*, *C. dolosa*, or even *C. aurea*, on the other hand, would never root in it at all. These weaker-growing *Cattleyas* like a small shallow pan or basket, with rough, open material about their roots, and if room can be found for them near the glass, they will thrive much better than if arranged upon the stages. It may, in fact, be taken as an axiom that the larger growing a plant is, the larger receptacle, comparatively, will be required for its roots, and *vice versa*. The time for repotting depends a good deal upon the species. Most of the late summer and autumn-flowering *Cattleyas* of the *labiata*, *Dowiana*, and *Gaskelliana* types, also *C. bicolor*, *C. guttata*, and others of that section, may be potted when commencing to grow in the spring. *C. Mossie*, *C. Trianae*, *C. Warneri*, and *C. Mendeli* should have attention as they go out of flower. It is in many cases best to anticipate if possible the annual emission of roots from the newly-formed pseudo-bulbs, as this at once establishes the plants in their new pots. I have not unfrequently left *C. Warneri* until quite late in August before repotting, and the plants have at once obtained a good hold on the compost by the roots from the pseudo-bulbs that had flowered in July. *C. labiata autumnalis* does not usually produce roots from its pseudo-bulbs until after these have flowered and are commencing to grow again, and this should be the time chosen for repotting. Thus instances might be multiplied, but the principle is the same in all. Amateurs should, therefore, be on the watch and find out for themselves the proper time for their cultural operations, performing these not in a mechanical manner, but as a means to an end, and keeping this end constantly in view. This applies not only to potting, but also to heating or watering—in short, to all the various details of culture. No one acquainted with the habits of *Cattleyas* would think of exciting them, for instance, dur-

ing winter, as it is well known that growth produced under the conditions which obtain at this season has none of the robust character so necessary to free-flowering. *C. Mossie* is often late in making its growth, and should, in order to ripen this, have a light and warm position after flowering before the sun loses its power in autumn. *C. superba* and *C. Dowiana*, too, delight in this extra heat, but as they flower upon the current year's growth, this is required earlier—in fact all through the season, only being careful not to excite them after flowering for the reasons above mentioned. That gem among spring-flowering *Cattleyas*, *C. Lawrenceana*, coming as it does from British Guiana, naturally requires a good deal of heat and a light, sunny position not too far removed from the roof glass. Enough has been mentioned to show the point intended, and if cultivators note and provide for the peculiarities of their plants, they will find that with their success the interest in their collections will in a like manner increase. H. R.

***Cœlogyre cristata alba*.**—This is no doubt one of the finest white Orchids we have. The flowers are of the purest white, without the faintest tint of any colour whatever. Flowers are to hand from W. McDonald, and also "J. C.," which certainly show the results of good culture by the size of the individual blooms and the number on the spike. This fine plant, although at one time exceedingly rare, has during the past few years become more plentiful.—G.

***Oncidium Cavendishianum*.**—This fine *Oncidium* belongs to a group which is distinguished by being without pseudo-bulbs and having large, thick and leathery foliage. In this group are included such species as *O. Lanceanum*, *O. luridum*, &c., the leaves of these kinds being much larger and thicker than others of this genus having bulbs to support them. *O. Cavendishianum* was first discovered by Mr. Ure-Skinner in Guatemala, and it has since been imported from Mexico. It is now more than fifty years ago since it was first seen in this country. The flowers appear usually from April to May, but a fine specimen is now in bloom at the Exotic Nurseries, Cheltenham. The spike, which grows erect, often attains 3 feet in length, and carries a many-flowered panicle. The flowers individually measure about 1½ inches in diameter, the sepals and petals greenish yellow, heavily spotted with red, the latter being nicely undulated; the lip is very prominent, three-lobed, side lobes spreading, and, like the front one, of a bright clear yellow. It is a very beautiful and easily managed species, and the flowers are sweetly scented.—G.

***Epidendrum O'Brienianum*.**—What a splendid plant this is for growing where cut flowers are in demand, for when it gets thoroughly established it will continue producing its long flower-spikes throughout the whole year. At the Exotic Nurseries, Cheltenham, this fine hybrid is especially well grown. It is also astonishing the length of time the individual spikes will continue in perfection, for as fast as the lower blossoms fade, fresh flowers appear at the top. It is the finest of all the Reed-like *Epidendrums*, and the first hybrid in this genus combining the brilliant scarlet-carmine of one parent with the deeper purple of the other.—G.

***Odontoplossum luteo-purpureum*.**—A fine specimen of this grand *Odontoglot* is now in flower at Mr. Cypher's nurseries at Cheltenham. It bears a spike of sixteen blooms. These individually measure over 4 inches in diameter and are exceedingly showy. The sepals and petals are nearly equal, oblong and lanceolate, the latter being more wavy and undulated, of a bright yellow, blotched and marked with rich brown; the petals are almost entirely bright chestnut-brown, tipped yellow, and with a narrow line of the same colour running across each. The lip in this plant is very conspicuous and contrasts well with the other

dark segments; this is of a clear yellow with a large chestnut reddish blotch immediately in front of the crest, which is composed of many teeth-like processes, all pointing forward. This fine species is one of the most beautiful kinds in the whole genus, and was discovered in New Grenada growing in the forests on the mountains at about 8000 feet or more elevation, which indicates that quite cool treatment under cultivation is necessary. In growth and habit the plant much resembles the popular *O. erispum*, but is larger in every respect. It will succeed well when grown with *O. erispum* and always flowers freely. There are many varieties of this plant, all of which are decidedly beautiful and easily recognised as belonging to this fine type.—W.

***Sophrontia grandiflora*.**—During the present season I have been pleased to see how well this brightly-coloured little epiphyte has been flowering, especially around the neighbourhood of London, but although in these localities the plants are kept in excellent condition and induced to bloom freely, it is not possible to produce such fine blooms as are seen on plants that are cultivated in a country atmosphere. I am in receipt of several flowers from various correspondents in different places, all of which show finer colour than those grown nearer town. The finest form I have comes from Mr. J. Cypher, the flowers being of large size and good shape, the shade of rich orange-vermilion being brighter than I have seen on any previous occasion. This little plant is without doubt a grand Orchid, especially for amateurs, as it occupies but little space and succeeds well with quite cool culture.—W.

## COMPARETTIAS.

ALTHOUGH it is early in the season for these plants to be in bloom, I was agreeably surprised to receive flowers of *C. falcata* from a friend who is a beginner in Orchid culture, but who, judging from the spike sent, is in a fair way to success, as the plant, purchased at a sale of an old collection in the neighbourhood, was not in the best of condition when it came into his hands. The members of this genus have long been in cultivation, but have not made great headway, either from lack of interest or because growers, as a rule, have not been successful with them. The cause of this non-success, I think, in the atmosphere provided for them, and not because of any inherent weakness in the plants. As I have before stated in these pages, small-growing Orchids of many kinds will not thrive in a house where the temperature is always fluctuating and heat and moisture are not effectively balanced. These plants will be most satisfactory in a house such as suits the New Grenadan *Odontoglots* as *O. grande*, and they undoubtedly like a moisture-laden atmosphere all through the season as far as practicable. They may be grown on blocks with Sphagnum Moss, provided due attention is given to watering the roots and sprinkling the foliage while in growth, but they are perhaps safer in the shallow pans that are so freely used for dwarf Orchids. These must, however, be only of sufficient size to allow of a very narrow margin round the plants, and must be filled nearly to the brim with drainage material, a thin surfacing of Sphagnum Moss being all that is required in the way of compost. The species named below are natives of the mountainous parts of Central and South America.

*C. COCCINEA* is an extremely bright and effective Orchid, flowering on the young or current growth; the racemes bear four or five bright scarlet and yellow flowers. The sepals are small and narrow, the lip broad and spreading. It flowers from September till November.

*C. FALCATA* is a similar species to the last named, but a better grower, and produces larger flower-spikes. The flowers have a purple tinge

which is very attractive. I have seen this plant growing well in a shallow wooden basket suspended from the roof with the cool section of *Odontoglossum* where the winter temperature never fell below 45°.

*C. macrolepton* is a native of New Grenada, and much more recently introduced than the preceding. The flowers are shaded magenta, with deeper spots. It grows freely, and generally flowers more freely than the other kinds named. Other older kinds are *C. rosea*, *C. speciosa*, and *C. saccata*. H. R.

**Ceologyne Massangeana** (*George Hemmings*)

—This lovely species will produce its spikes at all seasons of the year, and when once they commence they are developed with great rapidity. It is very free growing and a prolific bloomer, and one that requires but little attention to grow it successfully. Place the plant in a well-drained basket or pot and use fibrous peat and Sphagnum Moss. The plant should be suspended near the roof, in order that it may have the benefit of plenty of light, and the long, pendulous spikes will then be seen to the best advantage. The sepals and petals are buff-yellow, the lip very fleshy, dark brown, prettily lined and marked with light yellow. It has been known for a number of years and is supposed to be a native of Assam.—G.

**Masdevallia Veitchiana grandiflora**.

—This fine species of *Masdevallia* has a flower of remarkable and lovely colour. A fine flower of the true variety of the *grandiflora* form comes from Mr. James Cypher, of Cheltenham. This is of fine size and substance, the upper sepal being entirely covered with rich crimson papillae, as is also the larger portion of the lower sepals. When looking at the bloom sideways it is of a bluish shade, intermixed with orange-scarlet and a colour which is indeed very difficult for an artist to reproduce. The original *M. Veitchiana* was discovered on the Andes, of Peru, at some 11,000 feet or 12,000 feet elevation nearly thirty years ago. This, however, has smaller flowers and is less brilliant in colour than the variety above referred to.—H.

**Cymbidium Lowianum**.—Several flowers of this useful Orchid are to hand, some being very much better than others. Those from J. Edwards are very green and the blotch on the lip is of a very light shade; this cannot be called a good variety. The finest I have seen this year is that from "G. R.," which has sepals and petals of a fine yellow, the blotch on the lip of a very rich reddish crimson, distinctly bordered with yellow. I am not aware of the greatest number of flowers that have appeared upon a spike, but last season one came from Mr. Letts, of Aske Hall, which had either twenty-seven or twenty-nine finely-formed blooms.—W.

**Cypripedium Godseffianum**.—I recently noticed a fine and highly coloured form of this beautiful hybrid, which is no doubt one of the most beautiful crosses effected with *C. hirsutissimum*, the other parent being *C. Boxalli*. This was raised by Mr. Norman C. Cookson, of Wylam-on-Tyne, and flowered for the first time about six or seven years ago. The dorsal sepal is pale yellow, spotted with small dark brown spots; the petals are nicely undulated and light yellow at the base, becoming quite a pale blue on the apical half, and densely spotted with blackish dots; the lip is of good shape and of a pale brownish yellow.—W. H. G.

**Odontoglossum nebulosum**.—*Odontoglossum nebulosum* is an old inhabitant of our gardens, and a very useful species for growing in the cool house, its large flowers being very acceptable about April and May, which is its usual time of blooming. At the present time it should prove even more valuable, but it is not to be expected that the plant will continue to flower so early in the season. The bloom sent by W. Turner appears to be of a very good variety, with the spots of a nice red-brown, but it is a pity that a little more care is not taken when packing cut flowers,

so that they will arrive at their destination in a fresh condition. This plant is a native of Mexico, and by no means a new kind, as suggested, it having been imported into this country about sixty years ago. The cultivation of cool-growing Orchids was not then understood, and consequently such kinds as this and many others failed to grow well. Thus some of the best kinds were not again introduced for many years later. This species varies considerably in its flowers, some being larger and some more heavily spotted than others. In the variety *O. nebulosum can didissimum* the spotting is almost absent, whilst some range down to dark brownish red. Do not allow the plant to become weakened by leaving the flowers on too long.—W.

## ORCHARD AND FRUIT GARDEN.

### PRUNING FILBERTS.

In many gardens both Cob Nuts and Filberts are the most neglected of all fruit-bearing trees, seldom getting properly pruned, manured, or otherwise attended to. This may arise from a variety of causes, such as being in out-of-the-way situations, and therefore possibly forgotten in the press of work that must be done in the houses and kitchen garden, March and April being always a busy time, and which is the right season for pruning the trees. All experienced Nut growers that I have known never prune until after the flowering period, their contention being that it is desirable to have as many catkins as possible, so that plenty of pollen may be obtained to set the female flowers. That their theory is correct must be palpable to all, for if the pruning were done early many of the male blossoms would of necessity be cut away, and there would be a danger of an insufficiency of pollen to secure a good set or crop. In my own case this year most of the catkins were more or less developed before the severe frost set in, and I am afraid they will be of no value for fertilising. Fortunately, the common Hazel in the hedgerows is not so forward, and branches may be cut from the trees with plenty of catkins thereon and placed in the Filbert and Cob Nut trees when the female flowers expand, thus aiding Nature to perfect the functions of the trees.

Those who attended the conference held in connection with the great fruit show at the Crystal Palace will remember the advice given by Mr. Wise in his excellent paper on the pruning of Nuts, in which he stated that the centre of the bushes or trees should be cut out, leaving the main outside branches to grow on unchecked for two or three years, and then bending them outwards and securing them to stakes, which gives a large and prolific bush in a few years from time of planting. The trees that I saw at Lord Sudeley's immense fruit plantation at Toddington trained on that system were models of what such trees should be, and by the plan of bringing down the main branches in the manner described it appeared to act as a check on any grossness of habit, and induced the formation of plenty of small wood adapted to produce heavy crops of Nuts. No graver mistake in Nut culture could be made than to cut away the major portion of the fine twiggy wood, leaving all the strong shoots, as it is the thin wood that really bears the crop, but if late summer pruning is done no strong shoots will be present in spring, as they will be either entirely removed or shortened back, according to the judgment of the grower. At the same time while plenty of thin wood is desirable, care should be exercised that it does not become too congested or too thick in the middle of the tree, thereby impeding light and air and also acting as a harbour for insect foes. All suckers ought to be removed as they appear unless required for increasing the stock; when allowed to grow they act as robbers to the trees and do more or less injury to them. Immediately it is seen that a good crop of Nuts

is assured, a mulch of good manure will act splendidly, causing the foliage and fruit to attain a large and healthy size, and assisting the trees to form fruit-buds for another year. No trees pay better, if so well, for liberal treatment as Nuts, and yet few if any trees receive so little aid in that respect in many places. Even the common Hazel appreciates a dressing of manure, being almost unrecognisable after such an application, the Nuts acquiring a much improved appearance, also being produced in very large clusters.

W. G. C.

**Bullfinches and fruit buds**.—I hear on all sides lamentable accounts of the great damage done to fruit trees—particularly Plums and Gooseberries—by bullfinches and other birds, but chiefly the former. It is all very well to advise people to protect the feathered tribe, but if these sentimental people suffered a serious loss in their pockets year after year they would alter their opinions and say with me, "Kill every bullfinch you possibly can."—W. G. C.

**Grape Mrs. Pince**.—Mr. A. Young recently referred to this late Grape and notified that it did well with him. It may interest him to learn that it does well at several places in East Anglia. At Blickling two years ago I saw some magnificent bunches in September; they were of good size and well-shouldered, the berries being of extra size and beautifully coloured. On questioning Mr. Ocle, the gardener, as to the cause of its superiority, he remarked that when the border was made a large percentage of lime refuse was incorporated with the soil, and that he really thought this was the secret. This is a grand Grape when well done, but when only indifferently coloured, as it is in the majority of cases, it soon shrivels. It used to do wonderfully well at Cromer Hall some years ago, and I believe the soil in that locality is of a limy nature. Overcropping is not the only cause of bad colour in Mrs. Pince, as I have known cases where only a few bunches were allowed to remain on strong Vines, yet they were almost red. I think soil and situation have more to do with the success or otherwise of many Grapes than general management, and with Mrs. Pince in particular. Those capricious Grapes Duke of Buccleuch and Golden Champion do better at Hutton Hall than in many places, the treatment given to them by Mr. McIndoe being the same as that accorded to the majority of other sorts at Hutton. This leads me to think that the bracing air of the Cleveland Hills suits these two white Grapes, and prevents the appearance of the dreaded spot, which practically spoils these varieties. Mrs. Pince is a Grape well worth experimenting with in the shape of grafting and inarching, as there probably exists some variety which used as a stock would produce perfect bunches and berries of this highly-flavoured Grape.—J. CRAWFORD.

**Apple Barnack Beauty**.—I was much pleased to note a paragraph in a recent issue of THE GARDEN referring to the many merits of the above Apple and recommending it for more extensive planting. From the fact of seldom seeing it mentioned I was afraid it was an unsatisfactory variety generally, but the comments upon it by "G. C. R." coupled with the valuable testimony of such an able fruit grower as Mr. Woodward, of Barham Court, have dispelled the illusion. Having had the pleasure of visiting that astute gardener and fruit grower, Mr. Gilbert, Burghley, some twelve years ago, he spoke strongly in favour of Barnack Beauty (although never certificated, as he naively remarked). Ultimately he kindly sent me a plant of it to try, and although a light, thin stony soil is the reverse of an ideal one for Apples, yet this variety has made nice clean short-jointed wood, free from causer (the bane of Apple trees here), and bears annually heavy crops of well-coloured fruit of good eating and keeping qualities. It is a variety I should regret to be without. The knowledge that it thrives so remarkably well under good cultivation and in favoured situations is gratifying, and perhaps its value for general

planting is somewhat enhanced by its proving satisfactory under adverse circumstances such as ours.—GROWER.

#### APPLE PEASGOOD'S NONSUCH.

THIS is one of the best of the newer introductions and of good quality, useful either for cooking or for dessert. It is one of the best exhibition fruits. In appearance this fruit is somewhat like a good form of Blenheim Orange, less conical perhaps, but highly coloured when well grown. It does well in Kent, and I well remember the grand examples shown at the R.H.S. congress held at Chiswick in 1883 by Mr. Haycock, then in charge of Barham Court Gardens, Maidstone. This Apple being at that time less known was of great interest, and from that date appears to have been planted largely. The fruits shown weighed 1 lb. each and measured 13 inches to 15 in. in circumference. Those figured were grown at Sittingbourne, in Kent. I find this Apple

will command the best price; indeed, there is always a greater demand for such fruits than others. I am well aware we have any quantity of Apples fit for use at the time this comes in, but we have few approaching it in appearance. Most of the imported fruits sent to this country are sold because of their appearance, as a poor-looking, home-grown fruit will stand no chance against the brilliant foreign importations. I have seen this variety recommended as suitable for orchard culture as a standard, but as such I cannot advise its culture, as with me it does not fruit so freely as when grown on a dwarf stock as a bush. My experience may not be similar to that of others, but as a standard it will take some years before it bears, and in this way it much resembles the Blenheim. This latter is slow in

ing the foliage thin seems a new departure in the culture of this Grape, but one to be remembered and practised if success is to crown our efforts.—A. L., *Beaulieu*.

**Apple Mannington's Pearmain.**—I quite agree with the remarks of "H. C. P." on this Apple (p. 111) as to this being one of the finest late dessert Apples in cultivation, and one that should be extensively planted where quality and colour are valued. Lady Sudeley, so highly spoken of by "E. M.," is another excellent early dessert Apple, and is one of the best flavoured Apples grown in its season.—A. L., *Beaulieu*.

#### FLAVOUR IN FORCED STRAWBERRIES.

MANY complain that forced Strawberries are flavourless, insipid, and not at all profitable when their cost of production is considered. I do not intend to go into the question of cost, as it would take up too much space. Many things produced in a garden must not be looked upon as paying, whilst I know of several growers who force many thousands of Strawberries, and who would soon give up the work if carried on at a loss. Such large growers do not force at this season, as they get their plants to fruit at the end of April or for May, the latter month chiefly. There is a splendid demand for good fruits at that time, and they are sent to market little inferior to the best fruit from the open ground. By supplying the market at the time named the large grower can get well-flavoured fruits, as he does not force hard. Such fruits always sell well, and are never a drug in the market at the time named. Many growers still place chief reliance upon the well-known Sir Charles Napier. The fruit is not equal in flavour to British Queen, but I am sure it is superior to others I could name provided the plant receives the right treatment at the ripening period. In a short note about flavour I do not intend to enter into cultural details, my aim being to point out that flavour in these fruits is at times overlooked.

For years I have endeavoured to gain this good quality, though at times it cannot always be secured. Seasons, want of time, hard forcing, and other minor details prevent the plants receiving the necessary attention.

Good flavour cannot be got

in a steaming hothouse with a deficiency of air. Many good cultivators advise removal of the plants to a cooler and drier house, and excellent advice it is, but most gardeners are handicapped. Labour is none too plentiful and the fruit must be gathered from hothouses, flavour not being considered at the finish. On the other hand, large growers with nothing else in their houses get better flavoured fruit if they can lower the temperatures and thus finish their fruit, so as to get size and colour with firmness combined. Of late I have reserved a small lean-to house holding several hundreds of plants as a finishing house, and am much pleased with the results. The plants are placed here as soon as the fruits are partially coloured and will keep good a long time, when gathered being equal to the best fruits in the open as regards flavour.

*Apple Peasgood's Nonsuch. From a photograph sent by Mr. F. M. Ramell, High Street, Sittingbourne.*

does well on the French Doucin and Paradise when required to fruit in a small state. The fruits are of greenish-yellow colour, flushed and streaked with red, soft and of excellent quality. It is not a keeping variety, being at its best in October and November, in colour much resembling the well-known Cellini. This variety was recently exhibited by Mr. Payne from the Palace Gardens, Wells, Somerset, he staging the six largest fruits I have seen. They were grown on a south-east wall and gathered from a tree which had only been planted seven years, the fruits being thinned to sixty-two, and those exhibited weighed 2 lbs. each, none being under 1 lb. Some fruit growers may ask if these large fruits are worth special culture, to which I must say, yes. Fine fruits of any kind are always admired, and, as most growers well know,

coming into bearing as a standard till it attains a fair size and age. The fruit being so fine, when required for special purposes this Apple is worthy of a west wall, as in such a position when the fruit is thinned it is superb. It should be in all collections where good fruits are required.

G. WYTHES.

**Grape Mrs. Pince.**—I was very pleased to see Mr. Young's able remarks on p. 111 in response to "Wiltshire Gardener" on his treatment of this grand Grape, which I have no doubt will be read with interest by many of your readers. I quite agree with him that the most fertile cause of failure is overcropping, as with me it is very free in showing fruit and also sets well; consequently requires a firm hand to reduce the number of bunches. Mr. Young's treatment of keep-

The house faces north and the stages are slate slabs, with a little finely sifted gravel for the pots to rest upon. The advantage of such a house is that, no matter what time of day the fruits are gathered, they retain the luscious flavour so desirable, as the plants are not roasted as when finished on hot, drying shelves. I have noticed that the fruits of Sir C. Napier, Auguste Nicaise, Noble, and others not specially remarkable for flavour are all that can be desired, given cool treatment at the finish.

Many late forced fruits would be much better flavoured if forced slowly, and of late years I have discarded shelves for the latest lots—I mean shelves at the back of houses or make-shifts, not proper Strawberry houses, as on such shelves it is almost impossible to get the desired flavour in the fruits, the plants are subjected to great fluctuations of temperature, and are rarely moist or in a free-growing condition an hour after they are watered. To get flavour with late fruits, grow the plants on a cool coal-ash bottom, as the roots revel in such treatment, and there is less fear of that terrible pest red spider, which is one of the greatest evils growers have to contend with, and one that greatly affects the flavour of forced Strawberries. I have lifted the much-abused Noble when short of plants late in April and planted it in cold frames. Treated in this way the flavour of the fruit was greatly improved. Forced Strawberries when given a little more care at the finish should not be regarded as being worthless and bad flavoured. I consider them invaluable, and a fruit all growers, gardeners especially, should do their utmost to improve.

GEO. WYTHES.

## ROSE GARDEN.

### IN THE ROSE GARDEN.

WHAT a contrast between this and last year. Then we had a fine lot of growth that had come through the winter well, and our Roses were so precociously forward in breaking, that many of us had much fear of frost. As time went on we seemed fairly safe from this enemy to spring growth. But, alas, the foe was only waiting, and showed his teeth in an unmistakable manner early in June. Last season many were eager to prune by the end of February, and by the close of the following month our Roses were so forward, that we seemed altogether behind where the knife had not finished its work. We were favoured with good growth last autumn again, and until the middle of January it looked safe. But now our hopes are again shattered. Not much danger of precocious growth; indeed, many of us will be fortunate to have saved any serviceable wood upon our strong-growing and early-blooming Roses. Nor shall we have much doubt about pruning, for by the time the soil has got warm once more spring will be with us, and after the dead wood has been trimmed out we shall find a very scanty remainder. At first sight it is somewhat singular that those Roses in sheltered and south aspects should be much worse than those upon a northern wall that were continually frozen for so long a period, and also subjected to the full effects of the keen north-east winds. I do not think this would have been so noticeable had the weather not been so bright. It is quite certain that the sun thawed the wood in these spots for an hour or two during mid-day, and that within a very short period they were again severely frozen. Looking back, I call to mind more than one instance where the weather was severe for a brief period only, sometimes for one night

alone, and in these cases there seemed equal damage done whatever position the Roses occupied. In another case a plant of Marie van Houtte was incased in ice for weeks, and yet came out of the ordeal safely. A steady thaw set in and there was no repetition of the frost. In shaded spots the Roses appear fairly safe again this year, but those in the sun are a sad wreck. Does not this point to the conclusion that even a prolonged frost of severity is far less harmful than successive frost and thaw? With the soil, and consequently roots, frozen to so great a depth, while the tops of the Roses were being dried up both by frost and sun, and experiencing two such opposing elements in rapid succession, I am not greatly surprised that the Roses apparently better situated are evidently coming out of the ordeal in the least satisfactory manner.

As a stock the Brier in all forms has proved much hardier than the Manetti, and buds worked upon the former last summer are comparatively uninjured in the case of dwarfs. Much of this is doubtless owing to the partial covering of snow, although I regret to say we had next to none. On raised stems the Rose-buds look very bad and there will be many blanks again, but from a different cause to that of 1893-94. Then it was the Briers themselves which failed, now it is the Rose. Once more we see that Teas are quite as hardy as the Bourbons and Hybrid Perpetuals, if we do not perversely choose extreme examples from each class.

At first glance beds of maidens look quite cut up, and, being generally grown upon open quarters, they have certainly had a most trying time. On the whole, however, young plants have stood the weather better than older ones. The two Roses least affected are the forms of Rugosas and Hybrid Sweet Briers, while Messrs. W. Paul and Son's Moss Zenobia seems almost untouched. Would that I could write the same of others.

RIDGEWOOD.

### VITALITY OF YOUNG AND OLD PLANTS.

ALTHOUGH too early for one to know the extent of damage caused by this remarkable frost, I can see that the plants which will pull through best are those that are one year from the maiden bud and some grafted plants of last season. We look for more vitality in young plants after they have grown somewhat away from the very tenderest stages, and the fully exposed wood of almost the whole of my young ones still has a healthy look, and is without the dry and nut-brown pith too prevalent in those of older standing. When short of a stock of Teas or Noisettes I have many times worked them up by grafting early in the year and then planting outside in June or July. Such plants grow away freely, and are equal, often superior, to any maidens from the bud, while a year is saved. It is a batch of these that are the most promising of our plants at present, the wood seeming almost unaffected. Old plants—the same bed that stood the test of 1880-81 and subsequent hard winters looks as if it must succumb now. Older Hybrid Perpetuals, too, are looking bad, while a few worked similar to the Teas are comparatively untouched, notwithstanding they are the more delicate varieties such as Horace Vernet and new Roses whose numbers were short.

It is the same when cultivating in pots. We find a young plant from two to four years far more profitable to grow than after the wood has become old and sere. True, we can keep them young in a manner by removing this old wood as far as possible and retaining young growth. But to my mind the vitality and vigour of such plants cannot be compared to those of two to four years. The base is old and so are the roots. A few old plants of some variety much needed for

stock—Comtesse de Nadaillae, Souvenir d'Elise Vardon, and others—have been knocked out of pots and the whole of the soil washed away; then the roots trimmed and thinned out where coarse, and repotted into small pots of turfy and sandy soil so as to encourage new roots at once, potting on again into a richer compost. Healthy growth has generally followed such treatment. Other plants that seemed to have done their part as pot Roses have recovered when so treated, and planted out into a border as soon as the weather was warm enough to avoid severe checks. I have frequently noticed that wood grown under glass is more quickly affected than that which has been experiencing the many little checks and chills our outdoor Roses are subjected to at all times of the year.

**Rose Mme. Georges Brusnt.**—I am sorry the behaviour of the above hybrid Japanese Brier here does not justify me in confirming the high opinion expressed on its merits by "R." (page 83), but I must own that it has failed lamentably to come up to our expectations. The rugosa varieties are extensively grown here in large solid masses in prominent positions, which they worthily occupy, clothed as they are with ample healthy foliage of good colour, sheets of bloom and heavy crops of large attractive hews, which together make a nice show from early summer to late autumn. On the strength of its parentage and the high encomiums passed on it through the Press and other channels, a number of Mme. Georges Brusnt were quickly procured and planted alongside some of the rugosas, thus enlarging one of the clumps. From the outset they made strong satisfactory growth and bloomed freely; but, alas, each season they became so overrun with mildew as to become quite an eyesore, and even marred the appearance of the adjoining rugosas, so that after two seasons they have been removed and planted in a less conspicuous position in a wilder part of the grounds. This liability to mildew is unfortunate, for this variety is such a perpetual bloomer and the elongated buds are pretty and useful—a decided acquisition in this respect; but with this class and when grown in large masses one does not take kindly to be eternally applying insecticides, &c., in face of the fact that the superior rugosas take care of themselves, requiring neither lotions nor cosmetics.—J. R., *Merioneth*.

**Worthless new plants.**—In a recent issue of the new plant catalogue of a leading Continental nurseryman of the very highest character noted for the number of really good new plants, especially in the shrub line, which he has been the means of introducing into European gardens appeared the name of *Coriaria japonica*, about which (having raised it from seeds sent him from Japan without description) the nurseryman confessed he knew absolutely nothing, having been unable to find any notice or description of it in any botanical work to which he had access. All he could say about it was that the family was known in European gardens through *Coriaria myrtifolia*, and that its foliage resembled that of *Hypericum Moserianum*. On referring to that great and most authentic work of reference, "Index Kewensis," I found that this *Coriaria* was fully described by the late distinguished American botanist, Dr. Asa Gray in the "Memoirs of the American Academy," new series, vol. vi., for 1858-9, on p. 383. Not having these Memoirs myself, I sent the reference to a friend in the herbarium at Kew, asking him to be so kind as to let me know how *C. japonica* stood as to beauty and value as an ornamental plant in comparison with *C. sarmatosa*, figured on plate 2470 of the 51st volume of the *Botanical Magazine*, which appeared to be a herb with spikes of small and utterly inconspicuous greenish flowers of no value at all from a horticultural point of view, but said to be an extremely rare and botanically interesting plant from New Zealand. The answer received from Kew was that *Coriaria japonica* was considerably less

beautiful than the member of the family figured in the *Botanical Magazine*, and that I should not care for it at all. I think that it is much to be regretted from every point of view that new and unknown plants should be sent out by nurserymen before they have either proved them themselves and found them to be worth growing, or at all events received some reliable description of them from those who knew them in their native country and sent them the seed. The receipt of such plants when they turn out to be worthless must result in disappointment to the purchaser and discredit to the nurseryman.—BOSCOBEL.

## STOVE AND GREENHOUSE.

### LILY OF THE VALLEY IN A TUB.

THE Lily of the Valley crowns have been in the tub for about four years, but this is the first time there has been such a splendid show of blossom, fully one-half the crowns flowering. From the time they were placed in the tub they have not been disturbed and left out in the open. Just before winter sets in about 2 inches of thoroughly decomposed manure are put all

*Lily of the Valley in a tub. Engraved for THE GARDEN from a photograph sent by Mr. F. H. D. Kemplen, Wallberton Cottage, Dunedin, N.Z.*

over the soil, and this seems to have the effect of stimulating an early and vigorous growth. When the shoots are well up, tepid water is given every day, to which is added manure water twice a week when the spikes of blossom are well on. I have tried forcing this beautiful spring flower, but without success, and the attempts of our local nurserymen have also failed.

FRED. H. D. KEMPLER.

*Dunedin.*

**Ataccia cristata.**—This curious plant is seldom seen in collections, but the weird appearance of the plant when in flower attracts everybody, especially those who admire anything quaint in structure. I obtained a plant some eight or ten years ago after reading a note in THE GARDEN about it, and especially about the facility with which it might be propagated by detaching the gemmae from the rhizomes. I did not find that it could be multiplied so very readily, but the plants will throw out a growth or two from near the base of the rhizome; if these are removed with a portion of the rhizome and roots attached they will in time grow into flowering plants. The plant I have flowers every year, but not quite so strongly as I would like. The soil I use for potting is composed of good fibrous peat and sand with a little Sphagnum Moss. It is usually

potted with the Cattleyas; the only difference there is consists in the pots not having so much drainage material put in. The plant likes good drainage, but not more than 2 inches deep in pots  $8\frac{1}{2}$  inches or 9 inches in diameter. This is the largest size I have yet used for this plant. I find also that it succeeds best in the part of the house least exposed to the sun: the leaves become withered at the tips in a sunny position, and when this happens but little good results from it. I have just turned the plant out of its pot, and on examining the rhizome I find one feeble growth starting from its base; this with part of the rhizome and roots has been removed and planted by itself. The plant has been cut over and the part of the rhizome left has been potted also. The whole will be put into a hand-glass in the Cattleya house until growth commences.—J. DOUGLAS.

**The forcing Pinks.**—These are amongst the most esteemed of garden flowers for their sweetness and the delicate beauty of the petals combined with the pretty effect of their elegant leaves and growths. I have frequently in the pages of THE GARDEN written about the best way to obtain good specimens for forcing, and those who have followed my advice should now have a fine lot of plants. Pinks, Roses, and white Lilies are our favourite flowers for forcing, and they require very much the same treatment. They are

all liable to be attacked by the aphid tribe, which can be most readily destroyed by fumigation with a puff of flowers of sulphur on the first appearance of mildew on the Rose leaves. This is enough to keep them healthy and in good condition. I find the Pinks are impatient of too early forcing; they do not make good growths about the shortest days in the year. At that time the temperature should not be above  $50^{\circ}$  as a minimum, or even less in very severe weather. Now,  $55^{\circ}$  to  $60^{\circ}$  is the best temperature. The plants make good growths near the roof-glass of the forcing house, and a little weak liquid manure is useful to give a richer colour to the leaves and a more intense colour to the flowers, that is the coloured varieties, for it is well known to gardeners that forcing, especially in dull weather, has a tendency to produce a rather faded appearance in the flowers. This is one reason why I always insist upon plants that are being forced having as much air admitted as possible under the circumstances, and being placed where they can get a greater suffusion of light.—J. DOUGLAS.

**Anoiganthus breviflorus.**—This is one of the numerous Amaryllids that are found in South Africa, and, like most subjects from that region, it is essentially a greenhouse plant, in which structure, with a reasonable amount of attention, it can be depended upon to flower well. Blooming as it does in the first two months of the year it

is especially valuable, and though less showy than some other bulbous plants, yet it is very beautiful, as may be seen by referring to a coloured plate issued with THE GARDEN, July 18, 1891. It produces a solid, brownish bulb, ovoid in shape, from which are pushed out the leaves. They are rather stiff, nearly erect, about a foot long, and an inch in width. The flower-scape reaches a height of a foot or so, and is terminated by a loose umbel of blossoms. The individual flowers are nearly a couple of inches long, but so constricted at the base, that at the most they are not more than half expanded. It succeeds well in a mixture of two-thirds good yellow loam, with one-third leaf-mould, and a liberal amount of silver sand. When growing, water must be given pretty freely, but when at rest the soil should be kept dry, in order that the bulbs may be thoroughly ripened. In potting, the top of the bulbs should be just below the surface of the soil and the pots must be thoroughly drained, as, like many other bulbous plants, they will when in good condition stand for years without repotting. That this beautiful bulbous plant is not more often seen cannot be owing to its price, which in one of the Dutch lists lying before me is very moderate.—H. P.

### NOTES ON LILY CULTURE.

This is not the time to plant Lilies either for out of doors or for culture in pots, except, perhaps, late importations of *L. auratum*, but it is certain that it would have been better to have potted them up two months ago. Perhaps the best time to repot or replant Lilies is in September, at least for the varieties that flower early and ripen their stalks early, for in the case of Lilies as soon as the stems die down the bulbs may be transplanted or taken out of the ground to be repotted. Lily bulbs should never be allowed to dry, like the bulbs of Hyacinths, Tulips, and other things with hard solid bulbs. Where the bulbs have been potted and plunged deep in cocoa fibre refuse, it would be better to let them remain there while severe frosts last, but some straw or long stable manure should be thrown over them to keep intense frosts from penetrating too deeply. At one time I used to plunge them out of doors, but some varieties and some species would suffer from too much wet; for instance, *L. auratum* would do so, while *L. lanceifolium* and its varieties would not. The beautiful *L. tigrinum splendens* would also stand well out of doors. This beautiful Lily should be grown in every garden, and as a pot plant arranged in the greenhouse or conservatory few of the dainty exotics would equal it. The bulbs formed on the stems are all useful to produce plants; they should be taken off and potted when the others are done. My object in writing about Lilies at this time was not to give general details about their culture, but to warn growers of the fact that they must be attended to very carefully in the spring. Our plants have been plunged in frames, and are now pushing through the ground. These young growths are very susceptible to injury unless they are well managed. I take them up out of the plunging material and place them in a frame with the pots plunged to the rim, but with the growths quite free; in this position we seldom experience any frosts after the middle of February that are likely to injure them, and it is easy to throw a few mats over the glass if the cold is likely to be intense. The plants soon make strong, sturdy growth in these frames, and in fine weather the lights are drawn off, being replaced at night when there is danger from frosts. In May the plants may be quite in the open air, but they do best in a sheltered position, as high winds damage the leaves a good deal. Another way of treating Lilies grown in pots is to take them into the greenhouse and place them amongst other plants, but this is the way to get poor results. It is necessary to shade for the flowering plants, and the stems are drawn up weakly, the leaves poor, the flowers small in size, and petals thin. Greenhouse culture of all hardy plants is a mistake if they are intended to be flowered in the green-

house; they should be grown in frames or out of doors, and be taken into the greenhouse for flowering. If they are to be forced, they must be placed in a light forcing house near the glass roof. I force the *Lilium longiflorum*, the Bermuda type, and they are now fine sturdy plants showing bloom. They will be taken into the greenhouse as the flowers open, and with good management they will flower again in the autumn. I always get a spring and autumn bloom from the same bulbs of this fine Lily. J. DOUGLAS.

#### THYRSACANTHUS RUTILANS.

A WELL-FLOWERED plant of this member of the acanthaceous family was recently shown from Sir Trevor Lawrence's collection at Burford Lodge, Dorking. The plant itself was not a large one by any means, being to all appearance only a cutting of last year, in height not more than 18 inches, but it was flowering most profusely, its slender drooping racemes being clothed with blossoms, these racemes reaching below the pot. Its colour is an acquisition during the dull season of the year amongst stove plants, the example shown bearing evidence of its utility in a manner some might not think of, viz., as a plant for the dinner table. As decorative subjects, even when kept exclusively in the stove, when in flower plants of this *Thyrsacanthus* are a great boon. Many who have grown it have not developed its beauties to the greatest possible extent, this arising no doubt from a lack of knowledge as to its adaptability. Too often the plants are struck yearly, whereas it is best to grow on the plants and form them into standards of 3 feet or so in height. I have grown them myself to a height of 5 feet as standards; this height afforded the opportunity of inclining the heads forwards and partially over the pathway when in bloom, whereby a beautiful effect was produced. The quantity of flowers and the number of racemes on these taller and older plants are greatly in excess of what can be possibly had on the younger ones—all things being equal, *i.e.*, the cultivation in each case what it should be. Standards of this description will last for several years; thus propagation only need be done to keep up the desired quantity. When out of flower these older plants will do with a rest, being partially dried off and stood in an intermediate house. Growth should be started again from this cooler house when with the spring warmer weather sets in. In no case is it necessary to keep the plants in the stove to make their growth, even in the culture of young plants when once well established. During the summer a light, airy house will suit them well, the chief point to observe being the building up and solidifying of an enduring growth. In quite favoured localities I have grown *Thyrsacanthus rutilans* out-of-doors from June to September, thus saving room inside, the results being all that one could wish. The ordinary soil for stove plants (peat and loam) will suit it well. *T. Schomburgkianus* has darker flowers than *T. rutilans* and is often confused with it. JAS. HUDSON.

#### CANTUA DEPENDENS.

THOSE of us who can look back over a long gardening career sometimes regret that popular plants grown and greatly admired thirty or forty years ago are now seldom seen. One of the first plants I became acquainted with was this, and it was grown and flowered admirably in a small greenhouse. I well remember how proud I was when I was given charge of the small house which contained this and other plants as part of my duty. The plant had been recently introduced by the Messrs. Veitch, of Exeter, and it was grown in most of the leading gardens in the country, but not with uniform success. Many gardeners then, as now, did not consider that most plants require a season of rest and a time of growth, both being required to produce flowering growth. Another point is the importance of keeping the plants free from the attacks of red spider, a troublesome pest which saps the consti-

tution of any plant unless it is kept down. *Cantua dependens* is easy of culture, and with a most charming plant when in flower. Under ordinary greenhouse treatment it will bloom in April and May, and when a well-flowered specimen is produced laden with its fine tubular flowers about 4 inches in length, of a bright rosy red colour with an orange throat, hanging in clusters, one does not begrudge the small amount of labour to obtain such good results. The plants grow freely in good yellow loam, with some leaf-mould, decayed manure, and a little coarse white sand, not much, as I find the plant does not flower so freely if the compost is too open. The plants I had charge of flowered grandly in 10-inch and 11-inch flower-pots, but a young plant in a 4-inch or 5-inch pot must be potted into a 7-inch or 8-inch pot, and be allowed to fill that well with roots first, to be carefully repotted into the larger size before it gets what gardeners term pot-bound. Young plants can be propagated freely from cuttings of the nearly ripe wood inserted in sandy soil and covered with a bell-glass. The plants should be allowed to make their growth in a light, airy position. I believe hard-wooded plants are going out of cultivation, because they are spoiled by being grown in a shaded greenhouse and smothered with rapid-growing soft-wooded plants, at the same time being over-shaded owing to the necessity of taking care of the plants in bloom. When the flowering period is over the plants rest, and but little water is given them. Cut the young wood well back and let the plants start again about June. As soon as they have made a start turn them out of the pots, reduce the old balls, and repot the plants that were in 10-inch pots into 8½-inch pots. They will soon fill these with roots, and may be repotted again into 11-inch pots. When the plants have made a good start into that size place them in a sunny position out of doors, and they will soon ripen up their season's growth to produce flowering shoots for next year. J. DOUGLAS.

**Bottom-heat for Eucharis.**—Many while advocating bottom-heat for *Eucharis* when making growth are opposed to a continuation of it. When the bulk of the season's leaves has been made they lift the pots from the plunging bed, keep the plants much drier at the roots, and thus, as they think, prepare them for throwing up bloom when again returned to the bed. I do not like this system, having seen many plants succumb under it. One of the most successful growers of *Eucharis* constantly keeps his plants plunged in warm leaves. The beds are renewed in spring, the extra bottom-heat causing large numbers of flowers to appear. Growth starts simultaneously, and by the time this is completed the leaves have lost a deal of their former warmth, a condition suitable to the plants while at rest. Of course, while the roots are comparatively inactive much less water is required, but to withhold it entirely for a given time, as some do, is in my opinion very bad practice. I have a few plants in large pots standing on boards over hot-water pipes in a Pine stove. Here they have been for years, summer and winter. They grow freely and flower satisfactorily, thereby proving that a continual bottom-heat suits them.—J. C.

**Paullinia thalictrifolia.**—Introduced from Rio de Janeiro some twenty-four years ago, this beautiful climbing plant was for a time much grown (fine-foliaged subjects being then all the rage), but now-a-days, though a stock plant in some of the best nurseries, its merits do not seem to be recognised. To the lover of flowers alone there is nothing to commend it, as the beauty of this *Paullinia* depends upon its prettily divided Fern-like foliage. As a climber it may be grown in various ways, first as a rafter plant in the stove, or around a few sticks it may be so trained as to form a somewhat pyramidal-shaped specimen. I have seen it, too, on a fan-shaped trellis, which presented quite a mass of its elegantly divided foliage. In a suspended basket it is also very pretty. The shoots of this *Paullinia* are of a thin

wiry nature and clothed with triangular-shaped leaves, divided as in some of the *Thalictrium* (hence the specific name), and about 6 inches to 8 inches long. In some positions the young leaves acquire a slight bronzy tint, and are then additionally attractive. There is a variety (*argentea*) in which the leaves are suffused with a silvery grey, and very pretty it is. This *Paullinia* is not a difficult subject to cultivate, yet at the same time it needs a certain amount of care and attention. The roots are fine and delicate, and it succeeds best in a soil composed of two parts peat to one of loam and a very liberal sprinkling of silver sand. It is essentially a stove plant, needing as it does a brisk heat at all seasons. The flowers are said to be small, pale pink, and borne in little clusters.—H. P.

#### MYRSIPHYLLUM ASPARAGOIDES.

THE specimen sent by W. J. Luff is *Myrsiphyllum asparagoides*, a native of South Africa. It has been known in this country for nearly 200 years, but it was only to be found in few gardens till twenty years ago or less, when the long, slender sprays became very popular for table decoration, and it was then taken in hand by some of our growers for Covent Garden Market. The idea of employing the plant in this manner was, however, first brought here from America, where it was already largely grown under the name of *Smilax*, which is by some applied to it in this country, but it is really quite distinct from the genus *Smilax*, being in fact a near ally of the *Asparagus*, and, indeed, it is by some botanists included in that genus. The treatment required is simple. Being a native of the Cape of Good Hope, the protection of a greenhouse is, of course, necessary to its well-doing, and where grown in quantity, a warmth above that of a greenhouse is frequently maintained. It forms a mass of small tuber-like roots, from whence the slender shoots are pushed up. They are at first so delicate that a small slug will soon make havoc among a considerable number. When required to be used in a cut state each shoot should be trained separately to a piece of thin twine, as when wanted the entire shoot can be taken without any trouble; whereas if allowed to become entangled with each other it is a difficult matter to separate them. This *Myrsiphyllum*, too, makes a very pretty climbing plant for a rafter in the greenhouse, and in this way its bright green foliage is very attractive, added to which the small greenish white blossoms which are borne at this season of the year impart an additional feature. These flowers are supported on rather long, slender stalks, and a very elegant appearance they present when in quantity. They also emit a very pleasing perfume. The plant may be grown either in pots or planted out in a bed of soil prepared for its reception. A very suitable compost is two-thirds of loam to one of leaf-mould and a liberal amount of silver sand. In whatever position it is grown, thorough drainage is essential to its well-doing, as when growing freely it needs a liberal amount of water, but is at the same time very impatient of stagnant moisture. If trained around a few sticks, neat little specimens may be had in pots 5 inches or 6 inches in diameter, but it is when growing freely as a climber, and the shoots allowed to dispose themselves in a natural manner, that this *Myrsiphyllum* is seen at its best. It is very useful, too, for draping the front of a stage in the greenhouse, thus helping to take off the hard, formal appearance. Propagation is effected by division, which is readily carried out early in the year before growth recommences, while in the case of established plants seeds are often produced, and plants obtained in this way are by many preferred to divided specimens. Seeds of it can as a rule be obtained from most dealers of repute. They should be sown as soon as possible after receipt, using rather lighter compost than that recommended for established plants. The pots or pans should be well drained and filled to within an inch of the top with soil, then the seed may be sown

thereon and covered with about a quarter of an inch of the same soil sifted rather fine. A temperature somewhat above that of an ordinary greenhouse is best for them, and with the usual attention in the matter of watering the seedlings will soon grow, and when large enough must be potted singly into small pots. H. P.

#### SWEET-SCENTED RHODODENDRONS.

THAT class of Rhododendrons which has become so popular of late years, viz., the Javan or tubeflowered section, is not remarkable for fragrance, yet the blossoms of many kinds that require greenhouse treatment are deliciously scented. This group consists of a great many hybrid varieties, obtained by intercrossing various species that are natives of the Himalayas. One of these in particular (*R. Edgeworthii*) has very fragrant blossoms, and being largely employed by the hybridist was transmitted that desirable feature to its progeny.

*R. Edgeworthii* is very distinct from any of the others, and when out of bloom it is particularly noticeable by reason of the dense woolly tomentum with which the undersides of the leaves and young shoots are covered; while the flowers are large, widely expanding and pure white, with the exception of a blotch of yellow towards the base of the upper segments. This Rhododendron is rather straggling in habit, and some of the hybrid forms are more desirable for decoration. One of the earliest hybrids from *R. Edgeworthii* was *Princess Alice*, which was obtained by the intercrossing of this species and the little bluish-coloured *R. ciliatum*. Messrs. Veitch obtained a certificate for this from the Royal Horticultural Society as long ago as the spring of 1862, and it is still a very desirable form. The compact, freely-branched habit of *R. ciliatum* has served to modify the looser growth of its other parent. The flowers are in shape and size about midway between these two species, and before expansion they are slightly tinged on the exterior with pink. The blossoms of *Princess Alice* are very sweetly scented. *R. Edgeworthii* has, in conjunction with *R. formosum*, yielded some very desirable forms. One, *R. fragrantissimum*, was raised, I believe, by Messrs. Rollisson about twenty-five years ago; while the other, *R. Sesterianum*, is older still. Both have very large blossoms, deliciously scented, but the habit of the plant is somewhat straggling. To succeed with them it is necessary that the plants be pinched back freely during their early stages.

*R. Forsterianum* has a remarkably widely expanded flower, white, with the exception of the yellowish blotch. The parents of this are *R. Edgeworthii* and the Moulmein *R. Veitchianum*. An extremely useful group of this section of Rhododendrons was raised by Mr. Davis, of Ormskirk, between *R. Edgeworthii* and *R. multiflorum* (itself a hybrid). These varieties, to which the names of Countess of Derby, Duchess of Sutherland, Countess of Sefton, Lady Skelmersdale, and Mrs. James Shawe, have been given, are characterised by a much dwarfer habit of growth and a far greater yield of blossoms when small than any of those previously mentioned. The flowers of these are all white, slightly tinged in most cases on the exterior, but they are all certainly distinct from each other either in the shape of the blossoms, the habit of the plant, or the edges of the petals, for in some they are nearly smooth and in others prettily crisped. I have been very successful with the members of this group even in pots 5 inches and 6 inches in diameter by plunging them outside during the summer in a bed of cocoa-nut refuse. Under this treatment almost every shoot produces a flower-bud, and so fragrant are they all, that a bloom or two will be detected throughout a good-sized structure, while in quantity they have none of the heavy and (to some) disagreeable smell that results from a large quantity of flowers in a confined space.

A very neat-growing, freely-branched variety is *R. exoniense*, raised some years ago by Messrs. Veitch, of Exeter. This is between *R. ciliatum*

and *R. Veitchianum*, the influence of the latter parent being particularly noticeable in the glaucous under sides of the leaves. The flowers are of a beautiful waxy white, and borne in great profusion. Though very sweet, the perfume of this is scarcely so pronounced as in the preceding varieties. Another hybrid form remarkable for its fragrant blossoms is *Lady Alice Fitzwilliam*. Although the flowers of all these sweet-scented hybrids are white or nearly so, there is still a considerable diversity among them, while the habit of the plant varies greatly. While some can, as above mentioned, be grown into neat little flowering bushes in pots only 5 inches or 6 inches in diameter, there are, on the other hand, some that require to attain a good size before they are very effective, such as *R. fragrantissimum*, that needs a good deal of attention to get in bush form, but I have seen it with advantage employed as a wall plant in a greenhouse. It was planted out in a prepared border, and the position was well exposed to the light, so that it used to flower well. In such a position more particularly the syringe should be freely used among these Rhododendrons, whose greatest enemies are black thrips, but with ordinary care these give little or no trouble unless the atmosphere be too hot and dry. H. P.

#### WINTER-FLOWERING CARNATIONS.

I AM told that some of our large growers of these no longer propagate them from cuttings, but layer them in the usual manner. It would be interesting to know whether this latter method yields results equally good as the one hitherto generally practised. When I first made acquaintance with this class of Carnation it was not customary to increase them in warmth in the spring; indeed, annual propagation was not then considered at all desirable. The plants were kept for several years, and one frequently saw in trade establishments gaunt specimens of such as the Duke of Wellington, which had been cut from for half-a-dozen years. Such plants ran up to a height of several feet, were very woody, and thus merited the name of Tree Carnation. It requires a considerable amount of skill and much attention to obtain good flowering plants from cuttings rooted in early spring. The Carnation is impatient of artificial warmth, and some little time must be lost early in the season before plants raised in heat regain their natural hardiness. Layered plants cannot suffer in this way, and if the layering is done early they will be well established in small pots about the time when it is necessary to insert cuttings. They can go into the open at an early date, and there is no danger of their getting a check from the inclement weather that we are apt to experience in early summer. I do not wonder that growers for profit should be inclined to adopt this plan, for it certainly saves a lot of trouble and expense. If planting out for the summer is practised there is a distinct gain in point of time, for layers can go into the open ground with perfect safety quite six weeks earlier than plants raised in warmth, and these must be carefully hardened off. It is asserted that some kinds, such as *Miss Joliffe*, are wearing out. If such be the case, may not the constant propagation in warmth be in some measure the cause of this deterioration? An acquaintance who has grown this Carnation for market for some years tells me that for some reason or other he cannot fathom it does not now thrive as was formerly the case. The man is a good grower, and his treatment is the same at the present time as was the case when he had no difficulty in obtaining profitable results. There is no disease, but just a lack of sufficient vital energy to enable the plants to produce a profitable crop of bloom. I advised him to change his stock, and, if possible, get plants that had never been in artificial warmth, and from a locality far removed from his own. Here and there one meets with fine healthy stocks of this Carnation, and one would think that if it was wearing out the decline in vigour would be universal. I think that in the case of winter-

blooming Carnations generally it would be wiser to rely more on two-year-old plants. I have found, and especially with the *Souvenir* varieties, that I could always get more bloom from the space from them than from young ones. They do not run so much to leaf, but throw up a greater number of flower-stems, which, if the plants are in good condition, are very strong, and carry blooms of very fine quality. It is an easy matter to get really fine flowers in this way from December till May. Overpotting winter-flowering Carnations is a prolific source of failure. Just as good blooms can be got from 4½-inch pots as from larger ones. Carnations are not nearly so free-rooting as the generality of greenhouse flowers, and the roots are very sensitive to an overdose of water. By the end of September the pots should be full of roots if flower expansion is to go on through the winter months. If plants that are done blooming are put into the open air towards the end of May and shifted in July into pots one size larger, they will be quite root-bound by late autumn. Such plants, if well cared for through the summer, will produce a quantity of bloom just when most needed. Some varieties when thus treated will throw up some flower-stems towards the close of the summer, and these will give good blooms in November. Naturally these two-year-old specimens are not so attractive in appearance as young ones, but the Carnation in winter is more valued for supplying cut blooms than for creating an effect. Provided one can get plenty of nice flowers for button-holes and bouquet-making, it matters little what the plants are like that furnish them. The compost for winter-blooming Carnations should be of a nature that will not readily come into a close, sour condition. I like it to be sandy and with a fair proportion of well-decomposed leaf-soil, varying the amount of this according to the nature of the loam. J. C. B.

**Saintpaulia ionantha.**—Allow me to correct a slight error on page 133 of *THE GARDEN* about *Saintpaulia ionantha*. This lovely plant, which has been discovered and introduced into Europe by my son, never has flowers of 3 inches diameter, the coloured plate showing the flowers about their natural size. It grows best in a rich open compost in shady warm quarters and likes much moisture at the roots. The young offsets which the plant makes plentifully at the collar give the best plants if potted separately in proper time.—*BARON VON SAINT-PAUL, Fischbach, Silesia.*

**Acacias at Syon House.**—Few private gardens have such command of space to grow these plants as here. In the cool portion of the conservatory are huge bushes of such kinds as are not commonly grown. Many of the plants are allowed to run up to the roof and hang down with as few supports as possible. They also fill up odd corners and present a fine aspect. Many of the plants are grown in pots, and all that can be removed are placed outside in the summer. Those most beautiful just now are the following: *A. verticillata* is from 10 feet to 20 feet high, making a splendid bush, the flowers being deep yellow. *A. platyptera* is of different habit. *A. longifolia*, an Australian species, is very pretty and grows erect. *A. Drummondii* is a large pale lemon-coloured form from the Swan River and just opening its flowers. *A. dealbata*, the Silver Wattle, is very beautiful and of large size. This is a well-known species and one of the best. *A. cyanophylla* is a less known form with large yellow flowers; it grows about 20 feet high and is very effective, its long glaucous leaves on drooping branches being very distinct. There are other kinds, but those named are the most effective at this season.—*VISTOR.*

**Agapetes buxifolia.**—This has been well grown in the temperate house at Kew for years, and many notes have from time to time appeared in *THE GARDEN* calling attention to its beauty when in flower. Notwithstanding this, it is still very uncommon, and may in vain be sought for in most nurseries, though I venture to think that a fairly good demand for it might reasonably be

anticipated. This *Agapetes* is a native of the mountainous regions of Northern India, and is there said to reach a height of 5 feet, but being often found in its native state as an epiphyte, it is probably somewhat straggling. Under cultivation, however, it forms a neatly-branched little bush, clothed with deep green Box-like leaves, while the flowers, which are borne on the shoots of the preceding season, are tubular, about  $1\frac{1}{2}$  inches long, and in colour bright red. It blooms usually towards the latter part of February or in March and even April, while in summer the white berries, which sometimes succeed the flowers, are very noticeable. Apart from these features, it is at all seasons a pretty little evergreen shrub. As might be expected from its native habitat, this *Agapetes* needs the protection of a greenhouse; indeed, under conditions suitable to the Indian *Azalea*—it will succeed perfectly. Like most ericaceous plants, and especially those of a somewhat epiphytal nature, it succeeds best in a soil composed of sandy peat, into which the delicate hair-like fibres run with great freedom. Good drainage must be ensured, and at no time should the plant be allowed to suffer from want of water. Treated as *Azaleas* or greenhouse *Rhododendrons*, cuttings of this *Agapetes* root readily. They should be taken when about half ripe, and being dibbled firmly into well-drained pots of very sandy peat must be kept close in the temperature of a warm greenhouse till rooted.—T.

#### BOILERS AND PIPES.

THE late severe weather has tried the heating arrangements in every garden, and I have no doubt that hot-water engineers will soon have their hands full of work. During the last forty years I have tried a good many different kinds of boilers, and I have come to the conclusion that a good form of saddle if well set cannot be beaten. The best form in my opinion is the check-end saddle, and though the east-iron boilers are the cheapest, one feels safer with a wrought-iron boiler; and when a boiler set in brickwork has to be taken out, the expense of one breakdown doubles the cost of the boiler and labour alone. Permanency, therefore, should be considered. The action of many a good boiler has been seriously checked by bad setting, especially as regards the size of the flues. No flue round and over the boiler should be less than 7 inches in diameter, especially if the boiler be of large size, say capable of heating 1000 feet or more of pipe, and it is always advisable to have the boiler large enough to do its work easily. If it has to be pushed with a full draught, some loss of heat must ensue. But with a boiler well able to do its work after the heat has been raised, the fire may be worked with the damper nearly in and the bottom doors closed. Another very important matter is to have a fairly tall chimney. The taller the chimney or shaft, the better the fire works. A careful stoker will get a lot more work out of the fuel than a careless one, who forgets to keep his flues clean or to shut dampers and doors at the right moment. In very large establishments a good fireman will save the cost of his wages every year in the economical use of the flue alone, and there are other matters to be considered besides the mere saving of fuel. The forcing gardener is in a great measure in the hands of the fireman, and unless the fires are well managed it is impossible to obtain the best results. The presence of red spider and other insect pests is often due to overheated pipes at a time when they ought to be only moderately warm. There are many bright sunny days during a long spell of frosty weather, and if the fires are not damped down as soon as the sun appears, the pipes get too hot for healthy growth. Especially is this so where from motives of economy the pipes have been grudgingly used. During hard firing, with the pipes so hot that it is impossible to touch them with the naked hand, unless the work has been well put together, something is very likely to give way, and this is a very awkward

*contrivance* during hard weather. I remember during the severe winter of 1860 and 1861, especially on that particularly trying Christmas eve, I sat up all night with the fires and made the water boil out through the supply cisterns, and yet the frost got in. This, of course, was due to insufficiency of pipes. Again, I do not think there is much economy, especially if the houses are of large size, in attaching too many houses to one boiler. Where the houses are small I should prefer to have them grouped, but on the same level, and then there may be some economy in attaching several to one boiler. But where the houses are 100 feet or more long, requiring say from 1500 feet to 2000 feet of pipe, I should prefer to have them in pairs, each pair to be worked by one boiler. It is important that the boiler should be placed as near and well under its work as possible to ensure rapid circulation. It is often difficult to get a foundation for a deep stoke-hole in consequence of the water rising near the surface. When I dug my present stoke-holes, an old resident said, "Oh, you will never be troubled with water here," but in less than two years there came heavy and continuous rains and the fires were put out. This involved very heavy expense in securing an outfall for a drain, but the thing had to be done, and I am thankful for it now, for it is worth something to feel safe. I have lost all faith in cement for stopping out water in stoke-holes. It can be done, I suppose, at least every builder tells you so, but every man you employ runs you to endless expense and generally fails. If it were impossible to get an outfall for a drain, the best arrangement would be to place the boiler in an iron tank. I know a place where a very large sum was spent in trying to obtain a waterproof stoke-hole, when less than a fourth would have sufficed to have put in a strong iron tank that would have been permanent. E. H.

#### GROWING CROPS FOR PROFIT.

IT is all a question of energy and good management. Some men can get a living where others would starve. If "A Constant Reader" is fully prepared to work hard himself, has had some previous experience in vegetable culture, and has enough capital to stock a place and keep it going for, say, the first four or five months without any returns, then there is no good reason why he should not commence. The vale of Taunton is admirably adapted for the growth of early vegetables, and a considerable quantity are grown in that district for the markets. It is of the greatest importance that such men as "A Constant Reader" should start within at least easy carting distance of both a good market for a portion at any rate of garden produce that it does not pay to send to a distance, and where also a good supply of manure can be carted back. Taunton is a fairly busy town, or a good centre in an agricultural district, but there are no large manufactories of any kind, and the town seems to be already well supplied with all the common vegetables and fruit it needs. If, therefore, good land at £3 per acre rent can be got near to Minehead, that is where I should advise a start being made. One of the best markets for Celery is Cardiff, South Wales generally apparently having a great weakness for both Celery and Cucumbers. In all probability heavy vegetables, these including early Potatoes and Celery, could be sent by boat from Minehead to Cardiff and also Bristol, another good market, more cheaply than by rail, stable manure being had at moderately cheap rates from the owners of barges plying in the same directions. Small holders cannot afford to employ much manual labour unless a very superior system of culture can be carried out. The most successful, as a rule, are men with enough land to keep a cow or two as well as a horse, with pigs and poultry extensively. Much of the cultivation has to be done with light ploughs such as can be drawn by two horses, the extra horse being borrowed or hired as the case may be. In America the vegetable gardens of one acre and fields much larger are all so

arranged as to admit of the greater part of the work being done by horse-power, and, as a matter of course, "turning rows" or headlands have to be left. That very handy American invention, the Planet Junior cultivator, can be bought in this country for about £3, and one of these should be owned by most market growers and nurserymen. Of this combination, for that is what it amounts to, it has been rightly said that it ought to be regarded as indispensable. The machines are light, have adjustable bars so that they can be narrowed or widened at pleasure, and have adjustable and reversible teeth. They can be used either as a plough, moulder, or surface cleaner and cultivator. Drills for Potatoes can be formed, and some portion of the soil can be got out of trench for Celery with the aid of these light ploughs, while the former can have the ground among them loosened, and the moulding afterwards be done, whilst some part of the moulding up of Celery can be done likewise by means of this contrivance.

Both early Potatoes and early Peas, the latter grown without stakes, are regarded as profitable crops, and these would be or could be cleared off the ground in time for Celery to be planted. If the Celery has a fairly heavy supply of manure supplied to it, what will be left of this and the extra working of the soil should prove an excellent preparation for Potatoes and Peas, and the same routine might go on for years, especially if chemical manures were also used after the first year for the latter crop. From what I have seen of market gardening as practised by men who were previously private gardeners, not many of them go to work in the right way. They are too fond of variety and have to pay the penalty. Most small towns are kept well supplied with green vegetables by cottagers and small holders who hawk them from door to door, and the man who depends upon greengrocers to take all he can grow very frequently has to give the best portion of some crops to the pigs. "A Constant Reader" apparently does not intend to make this mistake, and he will do well to hold to the resolution to grow early Potatoes, Celery, and, let me add, early Peas extensively and almost exclusively till he can hit upon something more profitable. W. I.

## GARDEN FLORA.

### PLATE 1005.

#### HABENARIA CARNEA AND VARIETY.

(WITH A COLOURED PLATE.\*)

THESE are so well depicted in the accompanying illustration that any further description would be superfluous, a glance being sufficient to show how beautiful they are when well cultivated. It is in the winter treatment that growers are more apt to go wrong with these Orchids than while they are growing. The stems have died down, the plants are probably placed in an out-of-the-way corner and allowed to get quite dry. A gradual waste of the energies of the tubers and roots then sets in, and the plants are either killed outright or so weakened that they cannot flower. What they require is a low and rather moist temperature. The soil about them should never be allowed to be quite dry or be watered oftener than is necessary to prevent this. Then when they break up in spring there will be fine healthy shoots and robust flower-spikes. Coming as they do from Singapore, they delight in a strong moist heat while growing, and during this season must be kept moist at the root and be protected from the direct rays of the sun. After the flowers are past, they may with ad

\* Drawn for THE GARDEN by H. G. MOON in Mr. Sauter's nursery at St. Albans. Lithographed and printed by Guillaume Severeys.

vantage be inured to more sunlight, lessening the supply of water gradually and lowering the temperature. As hinted on p. 113, February 16, *Habenarias* are deserving of more attention than they at present receive, being a very interesting and attractive class of plants, and it is to be hoped that the publication of this plate may be the means of extending their culture.

H. R.

## KITCHEN GARDEN.

### TOMATO GROWING FOR AMATEURS.

AMATEURS are very apt to be over-zealous in the matter of starting Tomato growing. I mean they commence with either seed or plants earlier in the year than their conveniences justify them in doing. In order to be certain of a remunerative crop the plants must be grown quickly, though not rankly; they must have a fair share of room and sunshine, and must not be subjected to much moisture in the atmosphere. Very few amateurs are in a position to devote a well-heated house solely to Tomato culture. Instead of this they have to do the best they can with them in houses largely devoted to the growth of ordinary greenhouse plants, of which they contrive to collect far more than they can properly manage. The first step towards ultimate success with Tomatoes, if it rested with me, would be a rather wholesale clearance of miserably over-potted, diseased and insect-infested *Carnations*, worn out zonal *Pelargoniums*, old or flowerless *Primulas*, *Chrysanthemums* that have some time since ceased flowering, three parts dead *Indian Azaleas*, *Camellias* in no better plight, and such like. Those plants reserved would present a more attractive appearance after a re-arrangement has taken place, and the bedding plants being relegated to shelves, a space along the back of the front stages can be kept for Tomatoes in pots or boxes. Even if all this can be done it does not follow that February is a good time to start. It would be if a night temperature of from 50° to 55° could be maintained, but March or early in April is quite soon enough to start where fire-heat is somewhat sparingly used, while if fire-heat is only given when frosty nights are expected, early in May is quite soon enough to place the plants in their fruiting quarters. Puny, much-drawn-up plants produce fruit very sparingly or not more than one or two where there ought to be a cluster of six or more fruit, and it is very certain that plants which change to a sickly yellow colour owing to want of warmth or sunshine will never thoroughly recover.

Amateurs are frequently very undecided as to whether to raise their own plants or to purchase as many as they require. If they want several dozen plants, then I should advise them to raise their own, but if one or two dozen are all they have room for, then their best plan will be to buy them. They are largely advertised in the horticultural papers principally supported by amateurs, and I believe can as a rule be depended upon to come true to name. There are now so many varieties nowadays all presumably second to none, that it is a bewildering matter to select which shall be grown. For a quick early crop *Early Ruby* is hard to surpass, and either *Al Challenger*, or *Ham Green Favourite* would form a good succession. These latter are very productive varieties, the fruit being of medium size and good in form or colour, while if a handsome show variety is needed, try either *Duke of York* or *Perfection*. *Sensation* and *Hackwood Park* are a little coarse, but they possess good constitutions and crop heavily. If the packets received contain several score of seeds, do not sow the lot unless nearly as many plants are required, as crowded seedlings only spoil each other. Sow the seed very thinly in well-drained 6-inch or larger pots or pans, using fine sandy soil, give a gentle watering, place not far from the hot-water pipes at the warmest end of the house, cover with

a square of glass, and shade. Give a watering through a fine rose whenever the soil approaches dryness, and remove both the shading and glass directly the tops of the seedlings are well out of the soil. Before they become much drawn, transfer to a shelf near to the glass with a view to strengthening, prior to placing them singly in 2-inch pots. This latter should be done directly the plants have formed two leaves other than the seed leaves. Use light loamy soil previously warmed; lift the seedlings out of the soil with a label and sink them deeply down the sides of the pots. Those who have plenty of warmth at their command need not take so much trouble, nor need they place them in such small pots, but the amateur has to be most painstaking to make up for other deficiencies. The newly-potted plants should be stood on a warm staging, given a gentle watering—warm water both then and at all times being used—and shaded with a newspaper from bright sunshine. Directly they have formed a few fresh roots return to the shelves. In from a fortnight to three weeks after their removal to the shelves they ought to be ready for their final shift. No greater mistake than keeping them too long in small pots can be made. Directly they become root-bound the top growth hardens and becomes spindly, and if the fruiting quarters cannot be got ready for them by the time the plants are fit, give the latter a shift into 6-inch pots and keep them growing sturdily in these. This hint should also be profited by those gardeners who place their seedlings in small pots and are not able to shift them into their fruiting quarters either under glass or in the open just when they are ready for them.

Plants offered for sale are usually despatched by parcels post, and are, as a matter of course, shaken nearly clear of soil prior to packing in light boxes. In May or early in June such, when received, might be placed direct into their fruiting quarters, but earlier in the season they ought first to be recovered from the severe check given. If 4 inches and upwards in length and well rooted, place them singly in 4-inch or rather larger pots, smaller plants getting smaller sizes. Keep them somewhat close and warm till they are rooting afresh, when a sunny staging or shelf would be the best place for them. In this case, again, there should be no undue delay in transferring to fruiting quarters.

Next a few hints as to the fruiting quarters. Various sites can be turned to good account in Tomato culture, but amateurs will do well to depend principally upon plants arranged along the sunny fronts and trained up the roofs of the houses. A row of 10-inch pots might be set just clear of each other, a single plant going into each, or rough boxes of some description could be arranged in a row, and plants put out 12 inches apart in a single line. If the staging could be slated or tiled over, then both pots and boxes could be dispensed with, a ridge of soil 15 inches wide at the base and 10 inches deep being substituted, putting out the plants 12 inches apart. No particular mixture is absolutely necessary, but if good brown fibrous loam is plentiful by all means use it freely, adding to every four bushels one bushel of nearly fresh horse droppings. We have to be content with a mixture of three parts of good garden soil of a clayey loam nature to one of horse droppings, adding a sprinkling of road grit and fine mortar rubbish. If available, a 6-inch potful of steamed bone-meal should be mixed with every bushel of soil, or some special artificial manures may be substituted, using these at the rates advised by the vendors. In each and every case, or whatever moderately rich mixture of soils and manure may be made, either place it in the pots, boxes, or ridges a week prior to planting in it, or else warm it by means of a few heated bricks buried in the heap. Pots should be only about half filled at first, and equally good room be allowed in the boxes for top-dressings. See that the soil in the small pots is thoroughly moist prior to turning them out, and later on it is of the greatest importance that these balls of soil and roots be kept

uniformly moist without, however, badly saturating and souring the new soil surrounding them. Plant firmly and leave a hollow in the centre, so as to be able to water the centre readily and without using much of it. From first to last remove all the side shoots that spring from the axils of the leaves on the main stem, and when the points of the lead divide, as strong plants frequently do, cut away one of the two and the other will continue to extend upwards. Never delay this work of removing side shoots till it is necessary to use a knife, or otherwise there will be so much vigour wasted, light crops also forming on neglected plants. Stakes will be needed to support the plants till such time as the roof trellis is reached, and it is immaterial whether the latter consists of wires passed through galvanised eyes 9 inches in length, and screwed into the wood-work of the roof, straining these across the roof at a distance of 10 inches apart, or a trellis is temporarily formed with bamboo or other light stakes. If there are any very large ugly flowers in the centre of strong trusses pinch them out, as they are invariably followed by ugly fruit, and their removal will greatly strengthen the rest. During the flowering period give a smart tap to the stems everyday towards noon, this distributing the pollen and effecting a good set of fruit. Long before many fruits are beginning to swell top-dress with rich compost, taking care, however, to water when the soil underneath is getting dry, not waiting till the unoccupied fresh soil shows signs of dryness. Repeat this top-dressing directly that last given is crowded with roots, and a fortnight afterwards either give a light surfacing of special manure, or else use weak liquid manure frequently. Plants bearing heavy crops must be well fed up at the roots, abundance of water or liquid manure being most necessary in the case of plants with a much limited root run. Avoid wholesale mutilation of the leaves. If they smother the ripening fruit, then reduce them in size considerably, but do not cripple the plants by robbing them of the best of their lungs and digestive organs. A dry atmosphere, and which means a little to pair when the house begins to feel warm and moist, is most imperative. SELWOOD.

**Large Onions.**—I have been interested reading Mr. Iggullen's article on heavy crops of Onions and the right way to obtain such crops, but I have found—as doubtless Mr. Iggullen and others have—that large Onions are not the best for keeping. This year our large Onions have kept badly, while the small and medium-sized ones have kept very well indeed. Large Onions are excellent early in the season, but for keeping well give me specimens below the medium size of *Brown Globe*. The production of large Onions for exhibition is well understood by the cottagers in Lancashire. Some years ago the late Mr. Samuel Barlow took me through some of the best gardens in the neighbourhood of Middleton, and I was particularly interested in the culture of *Celery* and Onions. The Onion seed is sown on February 1 in very small pots, three seeds in the centre of a pot in good, rich, firm soil. One plant only is allowed to grow. The seed is not sown in a hot-bed, or, at least, if placed there to vegetate, is speedily removed, as the object is to obtain a steady vigorous growth from the first. The plants are kept near the glass until it is time to plant them out, and this is done as soon as the weather is favourable. They are planted in rich deep soil, and as the leaves develop they are carefully tied up to a trellis so that none of them will be bent, bruised or broken. None but enthusiasts in Onion culture would take such pains. J. DOUGLAS.

**Early vegetables and salads.**—I see frame culture and hotbeds are recommended to obtain early vegetables. This they will do, but they are rather inconvenient in small gardens. Where there is plenty of glass and ample space it is easy enough to obtain what is wanted. I sow Cabbage and Cauliflower seed in boxes, and it vegetates rapidly in the early vinery, the seed-

lings being pricked out when they have grown enough. To those who have no room for frames hoisted on to a hotbed, and who cannot afford vineries and forcing houses, I can recommend the appliances called ground vineries. They were invented by the late Mr. Thomas Rivers, of Sawbridgeworth, to grow Grapes. They are 2 ft. 6 in. wide at the base and in the form of a triangle, and in 7-foot lengths, with one close end only, so that when two are put end to end they are long enough to cover a Vine 14 feet in length. Some persons may say: How can you grow Vines in such a low structure, about 18 inches or so from the surface of the ground to the apex of the roof? Vines can be grown, and such as will produce excellent Grapes. I have grown capital Black Hamburgh Grapes in them, the bunches weighing from 1 lb. to 2 lbs. each. The Vines are pegged to the ground, and the growths trained over slates laid flat out on the ground. After a time I had plenty of Grapes in ordinary vineries, and for twenty-five years I have sown all my very early crops under the ground vineries. Early Carrots are sown, and between the rows of the Carrots Lettuce and Radish seeds. The Lettuce plants are thinned out to be planted in the open garden. Celery seed is also sown for the early crops. My own experience with Celery sown in boxes and placed in vineries, and even hotbeds, to vegetate is that it will often run to seed in the autumn, or even in summer, when seed sown under ground vineries will not do so. The vineries can if required be placed on the Vines in April after they have given the early vegetables a good start.—J. DOUGLAS.

**Potatoes.**—The season for planting these will soon be upon us again, and as varieties are so numerous one is almost puzzled to know what to plant. Those who have only the limited space of a kitchen garden in which to grow their supplies are not able to test the numerous new varieties, as every available inch of ground is required for the production of other crops. Of the many varieties introduced during late years, none are better adapted for the kitchen garden than Sutton's Supreme and Windsor Castle. With these two and a good early Ashleaf kind, a supply may be kept up the whole year round. Those, however, who have the command of field space can grow many more varieties. There is, however, nothing gained by growing so many sorts. It cannot be too deeply impressed on those who have not had experience in preparing the sets that one of the chief roads to success is to prevent the tubers intended for planting from making premature growth. All seed should be spread out on shallow trays or shelves, where they can be exposed to the light without fear of being caught by the frost. Fair-sized sets should be chosen, and if these are allowed to make short, stout growths before being planted, they will doubtless grow more evenly afterwards. I prefer whole sets, as from experience I find that such produce the best crops. During the dry summer of 1893 many of the cut sets failed to grow, particularly those that were planted late and had previously had the shoots rubbed off them. In some fields nearly one-half of the rows planted with sets so treated failed. In all cases the soil should be well worked and rendered as fine as possible previous to planting. Avoid covering the sets too deeply on heavy soil: if planted on the surface where sufficient earth can be drawn over them, they will do far better than if planted too deep.—H. C. P.

**Scarcity of salads.**—Doubtless this winter will have played sad havoc with winter Lettuces, but there are several ways of growing green salads if only required for cutting up for the salad-bowl. I do not intend to write on the value of Mustard and Cress, as everyone may grow this in quantity, but how many fail simply because they cover the seed with too much soil. The best results are secured by sowing on the surface and merely covering the seed with glass or paper till it has germinated. Again, how readily Dandelion is forced for salad in only a warm greenhouse under a stage, the leaves being of a pale green colour and of great value in the early spring. Chicory

is also good, but though readily forced, this with Dandelion may be too bitter, but is excellent if used with Mustard and Cress and other salads. The green tops or blanched portion of Celery is a delightful addition to the salad-bowl if used sparingly. The little-used Corn Salad or Land Cress is very hardy, and, sown in the autumn in quantity, is useful for early spring cutting. Watercress may be grown to perfection without a running stream. My method is to sow a box of seed in a frame or house in February, and when above the soil prick off or transplant into other boxes. As growth advances water freely, always using tepid water and light soils for the roots. When of good size, the plants lift well if properly hardened, and planted under a wall and sheltered for a time with copious supplies of water during the season, they will give a good supply at a small cost. But my note is more applicable to the production of salads even earlier than that advised by planting Watercress in the open. If some boxes are planted and kept indoors they give a lot of shoots, as, unlike Mustard or Cress, the more Watercress is cut, the thicker it grows. Another ready way to obtain small Lettuces for cutting is to use a small or early kind and sow in boxes, and when about 4 inches high to cut over in the same way as one does with smaller salads. A cheap kind is most suitable, and it is surprising what a lot of material an ounce of seed will produce. Of course such Lettuce is only good for the salad-bowl.—W. S.

#### PEAS FOR MARKET.

THE prolonged frosty weather has much interfered with the routine work of those who grow Peas for market. Growers like to get the seed for the earliest crop sown either at the end of January or early in February, but according to the present outlook there appears no chance of the seed being sown until the end of the month—in fact, not until it is time that the second earlies should be got in. My remarks apply chiefly to a class of cultivators that grow Peas largely for distribution in the great northern and midland towns. The acreage of each is not great. They for the most part hire a field or two where the land is suitable, only retaining the land long enough to get the crop. Preference is always given to a sandy, loamy soil that is naturally well drained for the earliest crop. Land that is somewhat heavier is reserved for the late crop and for Peas that have a stronger growth. The land is not, as a rule, ploughed until just before the Peas are sown, nor is it turned up too deeply, as it is usual for the ground to be manured before ploughing. If it be buried very deep the crop does not benefit from it, as early Peas are not deep-rooting subjects. I notice that the class of cultivators to which I allude are careful not to work the ground while it is wet. Especially is this the case with regard to ploughing. Harrows are used to level down the surface after the plough when the surface is fairly dry and the seed is put in by a drill.

With regard to the sorts of Peas grown for market, very few of the newer kinds find permanent favour. They are either too tender or not sufficiently productive. I am acquainted with one grower who last year tried William Hurst on rather a large scale, but it proved unremunerative as a field Pea. The growth was too dwarf to be productive. Harrison's Glory and Eclipse as second earlies are more largely grown than any other sorts, although not exclusively so. One would hardly expect to find the Blue Scimitar in favour now that there are so many other sorts to choose from. Those who grow it have, however, a select stock which they are careful to keep from deteriorating by judicious selection. As seen growing, the Scimitar appears able to resist drought better than any other kind I have seen, and it is not so subject to mildew. It, however, requires a fairly rich soil and deeper cultivation than is provided for the earliest sorts. Day's Sunrise is a profitable market Pea with those who have a rather deeper soil than is usual. It should have 6 inches more room between the rows than is allowed

for some of the others; 2 feet between the rows is what is generally allowed, but at that distance the plants are often crowded. As those with stronger growth are acknowledged to be the most productive, the distance might in good soils be increased 6 inches or 9 inches more. There is a round white-seeded Pea of the type of Daniel O'Rourke that is frequently grown by those who have warm and sheltered fields in which to grow it. This sort appears to be principally confined to the west country growers, who appear to take some pains to keep the stock pure. One grower in particular takes the trouble once in two years to grow a few rows in his garden for seedling, and weeds out any plants that do not come up to the character of the type. I have no doubt this is a good way to keep a pure stock. An inspection of the different crops when growing reveals the difference in the size and length of the pods as compared to those that are produced by a stock less carefully selected. An early crop of this sort very often proves to be the most profitable investment, although at no time do the growers experience any difficulty in clearing out their produce. I am assured it is the small quantities that are sent to local markets that do not realise so much money. The choice of a suitable soil and climatic influence are evidently the first considerations for those who wish to embark in the business of growing Peas for market. North Petherton, the district to which my remarks chiefly apply, is one of those favoured localities that in all respects is eminently favourable for the production of all early crops of vegetables, Peas especially. Seeing that it is not more than six or eight miles from Bridgewater Bay, it will be understood that climatic influence is all in favour of the cultivator. J. C. CLARKE.

#### NEW ASPARAGUS BEDS.

WHERE it is intended to plant fresh beds of this vegetable in spring they should now be got ready in order that they may duly settle. The mixing of the soil and general arrangement of the bed must depend entirely on the position, subsoil, and nature of the staple soil of the site it is to occupy. If favoured with a gentle inclination to the south, a fair depth of open porous soil, and a natural drainage, nothing more is wanted than a thorough trenching two spits deep and a free admixture of rich manure in a semi-rotten state, some rough leaf mould, road scrapings, and burnt refuse. In such positions raised beds are not necessary, and if the old-fashioned 4-foot beds are preferred, all that is needed is a 2-foot alley between them, stout stakes being driven in at the corners as boundary marks. On clay or very retentive bottoms the preparation is much more difficult, as if a free escape for all superfluous water is not provided, failure must ensue. In the first place the soil should be removed to a depth of 18 inches and of the required width, wheeled on one side, and where sufficient new soil of a suitable character is not obtainable, a portion of it burnt to be mixed with the new soil as the work of filling in proceeds. The bottom of the excavated portion should gently slope to one side, along which a main drain of 4-inch pipes should be laid, cross ones being connected at intervals. Where this drain cannot be let into the main drain of the kitchen garden, a well may be formed by digging a hole some 6 feet deep and filling it up with rough stones, clinkers, or brick ends, connecting the pipe with it. Then over the bottom lay from 6 inches to 8 inches of the same rough materials, and on this rough sods from any waste pasture, grass side downwards. In filling in, if new soil is not at command, that from some lighter part of the garden may be used, adding a large percentage of the opening materials recommended above and one-fourth of the original soil in a burnt condition. If horse manure can be had it will answer better for this bed than ordinary farmyard manure. It will also be advisable to raise the beds some 6 inches above the ordinary level, this increasing the warmth at the roots and keeping them in a drier condition generally. I have

now abandoned the old 4-foot beds on warm, light soils, preferring to plant in single rows, with 3 feet from plant to plant and the same distance between the rows. Thus favoured with plenty of light and air the plants make rapid growth and quickly meet each other, stout grass and plenty of it invariably following. J. CRAWFORD.

**The frost and the crops.**—Although some districts have been visited by intense frost than others, it is now pretty certain that very few green vegetables will escape the ordeal, and that prices will run high during the coming spring and early summer. In our own garden not only will all Broccoli in the open be killed down, but Cabbage sprouts and Brussels Sprouts also. Scotch and Asparagus Kale may escape, but they will be very hard hit. Young spring Cabbage plants and Spinach owing to their being well covered by the snow will, I trust, escape with only a crippling. We have had to cover over hand-lights with mats and litter to save the autumn-planted Cauliflowers. In this district from 36° to 40° of frost have been registered.—J. CRAWFORD, Newark.

**A note on Onions (E. B. C.).**—I consider it proved beyond a doubt that transplanted Onions are more to be depended on than those sown in the ordinary way. Yearly I sow a few, generally Bedfordshire Champion, but I never can depend upon them, while I am almost certain of having a crop of good bulbs in my transplanted lot. Cranston's Excelsior, Trebons, and White Spanish are my favourites. I do not sow any of the autumn Tripoli kinds, as they do not keep long enough. I sow Excelsior in boxes in September, stand them in a cold frame during the middle of the winter, and plant out as soon as the weather and ground are favourable in spring. These do not run to seed, ripen early, and give a heavy keeping crop worth harvesting.—J. B. O.

**A good forcing Bean.**—Those who require early dishes in advance of the first gathering in the open should grow the new climbing French Bean. This, grown in large pots with a few sticks to support the tops, is most valuable, as one may gather in quantity Beans of equal quality to those in the open. Many have cool or fruit houses where a few pots of this variety may be grown. I had it last season in a late Peach house, and was well repaid by the quantity and quality of the crop. Seeds sown early in April will produce nice dishes late in May at a season when choice vegetables are none too plentiful. My plants were in 12-inch pots, topped at 3 feet from the pots, grown in front of Peaches and well supplied with moisture overhead and at the roots. Those who have lofty houses may allow their plants to run up more, but they fruit freely when topped, and are more prolific than the dwarfer kinds. They do not get so tough, the pods being more fleshy and less stringy.—S. H. B.

**Duke of York Tomato.**—This new Tomato will soon get popular, and doubtless be a good companion to Perfection and Ham Green. The plant crops well and the fruits are of fine appearance, being scarlet, solid, with very few seeds, and just the size required for sale or private use, whilst they are of splendid flavour. I have seen some large fruits where thinning has been done, but this is no advantage. I would prefer those of medium size and in quantity. If the plants are allowed to carry eight to ten fruits in a truss, they will be quite large enough. For pot culture or planted out on a shallow bed, this variety crops well; the foliage is robust and the fruits ripen in quantity at one time. A large grower, who supplies the market in large quantities, told me this was a valuable variety for market.—G. WYTHES.

**Daisy Pea.**—This is a fine Pea for forcing in pots, boxes or any other method which may be adopted to raise an early crop for planting out. It is one of the Marrowfat section with a good-sized pod. For many years I have grown Stratagem, one of the best varieties ever sent out, because

of its free cropping and splendid quality when cooked. The Daisy Pea may be called a dwarf form of Stratagem and is equal to that variety as regards cropping and quality, but is an earlier or quicker podding form. Many grow the small white-seeded varieties for early supplies, but for pot or frame culture I do not consider them worth the trouble. For frame culture the Daisy is unequalled, as being only 15 inches in height it can be grown in a small space and the haulm is weighted down by the crop. In any position it is best to place small sticks to support the haulm, as the pods being large for the small top, supports are necessary. For sowing in the open to succeed such varieties as Chelsea Gem it is unequalled, and as it takes up little space it is suitable for all gardens. I gathered this variety the third week in May, 1893, on a south border from seed sown in the open. I admit it was an exceptional season, but I do not know of any second early variety more reliable or of better quality.—G. WYTHES.

**Crimson Ball Beetroot.**—Salads will be scarce this spring, so those who can secure a good stock of early Beetroot will find it a welcome addition to the salad bowl. The Turnip-rooted section is specially adapted for early culture, and if the seed be sown late in March on a warm sloping border, this variety may be had fit for use at the end of May. I do not know of a better variety than Crimson Ball for first sowing. It is a great acquisition to the list of Turnip Beetroots and the earliest I have grown. A pinch of seed is sown in a pan or box and the seedlings potted off. They are planted out when ready on a warm, sheltered border, and the one named is admirably adapted for forcing, if the term can be applied to this root. Sown in the ordinary way early in April, this variety is fit for use in June, and the roots when sent to table are of splendid colour. It is not a vigorous grower, so occupies but a small space, and the roots keep firm and good a long time if lifted and placed in soil on a north or shady border.—G. WYTHES.

#### EARLY CAULIFLOWERS.

THERE will doubtless be a considerable loss of the autumn sown plants with such severe frosts as we have experienced during the past month. To make sure it is well to prepare for the worst, and by sowing in heat to a certain extent make good any losses that have occurred. This vegetable is always more appreciated in the early part of the summer before the Peas, Beans and Marrows are plentiful, as later in the year the heads are stronger and not so much in demand, so that it is well to get a plentiful supply through May and June at a season they are more useful. For sowing in heat there is a good selection. For earliness, Snowball is one of the best. It is not large and should never get checked during growth, or it will turn in prematurely. Another very fine kind is Veitche's Foreing, a valuable small variety and suitable for pot culture. The heads are white, close, and just the size for table. If seed be sown now the heads will be fit to cut at the end of May. This variety is very dwarf and may be planted rather thickly. It is a splendid frame Cauliflower. The Pearl is good for early crops and the heads are of fine quality, but it is later than those named above. Last season I saw some very fine crops of Sutton's First Crop from plants sown early in February in frames. It is a splendid forcing variety, the habit being dwarf and compact. There are others, but those named are all good for sowing under glass for early supplies. I have seen it stated that there is no gain whatever in sowing the early varieties in autumn when the losses are considered. I do not think so, as the losses are few if the plants be sheltered from cutting winds and not exposed too much after frost. It is a great advantage to have a good stock of plants for early March planting. Grow the Waleheren and Dwarf Erfurt for spring cutting. When the seed is sown as advised at this date it requires care from the start. If the plants are not well hardened off there are losses at planting time. Sow a box of seed in a warm house, and

when the young plants are above the soil transfer them to a frame. There will be plants ready to prick out on a warm bed in a month's time, and these, given protection with a frame, will be fit to place in the open in two months from the time of sowing the seed. Plants grown in this way may, if required for a special date, be grown on a bed with frame protection, and will soon turn in if given plenty of liquid manure.

G. WYTHES.

**Dwarf Gem Brussels Sprout.**—I recently saw a splendid quarter of the above variety, which is certainly a gem, the sprouts being small or what may be termed medium-sized, of good flavour and very solid, whilst the plants are dwarf and hardy. This variety this season has stood the severe weather much better than the large kinds, and as regards flavour it is excellent. Many do not grow the dwarf kinds through their supposed small yield, but such is not the case, as the plants may be put more closely together, and if weight of produce be taken into account, they produce better crops.—G. W.

**Arctic Kale.**—As the name implies, this Kale or Borecole should be the hardiest of all Kales, and it certainly is, as with the thermometer below zero on several occasions I thought it would have been too much for most of the plants, but on February 18, when we had a slight thaw, this variety looked well, the hearts being quite sound, and there was no injury to the stem. I saw this variety exhibited in splendid condition last spring and made a note of it for trial, especially the purple variety, and it is very good at this date. Though the seed was sown late in April, the plants are well furnished with finely curled leaves, which quite hide the stem from view. This variety being a large grower requires space to develop, and should not be crowded in the seed bed. Treated thus, with the seed not sown too early, it is certainly one of the best winter Kales grown, and one that well repays for the room given to it. Those who require a quantity of late green vegetables for April or May should give it a trial, as after the first cutting the sprouts are produced in abundance.—G. W.

**Salading.**—The season being so far advanced, any remaining stock of Chicory may be stored in a spare pit or frame, protected at night from frost, and one light blanched at a time by covering with mats or litter. In Mushroom houses it comes on rapidly at this date, and cannot then be kept in a usable state for long; whereas in the former position it can be preserved for any length of time. American or Sand Cress may be sown in sheltered nooks this month, and small salad now brought on in cooler houses than heretofore. By these means the quality of all is improved.

**Planting Rhubarb.**—In gardens where there is much demand for forced Rhubarb, planting to a greater or less extent is necessary each season, or the stock soon runs out. Where large stools exist that are forced where they stand, or come on gradually by being covered with litter, portions may be detached from them and planted out on good open soil, well enriched with manure. Sufficient should be grown to allow of a number of three-year-old crowns being lifted for earliest forcing each year. Prince Albert is unsurpassed for the purpose, but care must be taken where a new stock has to be purchased, as this variety is hard to obtain. It is small in growth, but bright in colour and of delicious flavour. Johnston's St. Martin is likewise a popular sort for early work, and deservedly so. For making late growth and for making wine and jam, Myatt's Victoria is a capital variety. Later supplies may also be had by planting in positions somewhat shaded, even behind north walls.

**Early Turnips.**—In favoured localities and where the soil is of a warm, genial nature, a small plot may be prepared towards the middle of the month for sowing seed of Early Milan or the old white Dutch Turnip. Both of these are reliable

for early work, as they seldom run to seed. I would advise sowing both varieties, as Early Milan does its work in a little less time than the Dutch, the latter forming a good succession and remaining in excellent condition for a considerable time. In midland and northern districts it is advisable to wait till the first week in April before making this sowing, and even in warm counties raised beds and extra sheltered borders are necessary. Guano or powdered fowl's manure placed on the surface of the bed after the seedlings are thinned out helps to forward the crop, these being of a heating nature. A few Yew boughs placed here and there about the bed as soon as there are signs of germination form a good shelter and hasten growth. Protect from birds, or the crop is doomed.—J. C.

#### CAPSICUMS AND CHILIES.

THESE useful and ornamental plants do not appear so frequently in many gardens as they did some twenty years ago. In those days they were grown in quantity for room, table and conservatory decoration, and very effective they were. The only neighbourhood that I have seen any number grown of late years is about Cheltenham, and at the September shows until recently held there Capsicums formed a very striking feature in the collections of vegetables, and the judges certainly gave those collections the preference that contained a mound of these fruits in mixed or separate colours. Whether Capsicums should be counted a telling dish in a collection of vegetables is a question that I have had doubts upon, and some judges would be apt to disqualify such collections, no matter how well grown they were. The variety the Cheltenham growers principally favoured was named Bull's Nose, each fruit being about as thick as it was long and slightly corrugated. Of the very large type, Red Giant is one of the most useful, and was preferred to all other varieties in a former situation that I held, and where Capsicums were in demand, the fruits being liked best in a green state, the flavour being considered superior then to when they were ripe. The red and yellow Tomato-shaped are also excellent; the flavour is mild both in the green and ripe state. If a particularly hot Capsicum is appreciated, Long Yellow will be useful; even veterans from India or other warm climes I have heard exclaim against its pungency. For decoration, Prince of Wales is about the most ornamental variety; the fruit is small and of a bright yellow colour, set freely amongst bright green leaves. A lovely companion to this is Crimson Bouquet Chili. These two should be grown together, or rather placed side by side when decorating, as they form a striking contrast to each other both by under natural and artificial light. Coral Red is another charming Chili, the foliage and fruit being specially attractive by lamp or gas-light. It is also well worth growing as a table plant.

The culture of these useful plants is very simple, and, provided insects are not allowed to infest them, good results can be secured with the ordinary treatment given to half-hardy plants in warm districts. Seeds sown at any time in February in light, rich soil and placed in a temperature of about 65° will soon germinate. As the seedlings get well through the soil, it is advisable to place them near the glass to prevent their becoming drawn; short, sturdy plants are thus secured, that will be more fruitful than is possible with those that were drawn and weakly in their infancy. Immediately the seedlings are large enough to handle they should be transferred singly to small pots, still keeping them close to the glass. As the pots become full of roots a shift into a larger size will be beneficial, but, as a rule, a 6-inch pot is large enough for the final shift. In pots this size, weak liquid manure given several times a week in hot weather will assist the plants and their fruit, and by its invigorating influence help to keep down red-spider. Towards the end of May the plants may be placed in a warm and sheltered position outside, or, what is better still, they can be grown in cold frames, syringing the

plants morning and evening, and shutting up in the afternoon with a good sun heat. In this manner a dull, wet or cold season does not spoil them as if outside, and handsome plants are obtained that are useful for decoration or for their fruits. W. G. C.

## FLOWER GARDEN.

### SPRING BITTER VETCH.

(*Orobis vernus*.)

THIS is one of the best and hardiest of spring flowers, one of a family many of whom are beautiful and nearly all hardy. Its brilliant bloom has a curious and striking colour—harmony of crimson, purple and blue that is well set off by its bright, clean-looking leaves. It is a good plant for the rockery or the front edge of the flower border. The black roots form very tight and close masses—a fact the practical gardener becomes keenly aware of when every three or four years he has to divide the clumps.

*Spring Bitter Vetch (Orobis vernus). Engraved for THE GARDEN from a photograph sent by Miss Jekyll, Muashead, Godalming.*

It is wild in low alpine districts in thin woody fringes, but in the garden does well in almost any soil and position. G. J.

#### FLOWER GARDEN NOTES.

SPECIAL SUMMER FLOWERS.—FUCHSIAS.—It is only within the last few years that the greenhouse Fuchsias have been used for outdoor planting. Plenty of gardeners doubtless remember the time when the family was only represented outside by such sorts as gracilis, globosa, and Riccartoni. Following these came the variegated form of gracilis, with Sunray and Meteor to furnish a type of variegation somewhat different in style to that obtainable from Pelargoniums. Then there was an attempt with such old sorts as Rose of Castile and Mme. Cornelissen, and these proving a success, few flower gardens of to-day are considered complete without a goodly supply of Fuchsias. The old hardy sorts are not used so frequently as they might be, especially on borders of large size; the long graceful shoots with the small leaves and flowers tend to make the plants very effective when grouped with large-leafed shrubs or tall herbaceous things. They are seen to advantage on either side, a porch backing up plants of dwarfer habit. I have only had a failure with these Fuchsias once in thirteen years, and that was in the very trying summer of 1893; they could not hold their own on a light soil, growth was poor, and the flowers scanty and quickly over. A good mulching would have helped them, but the mulching material was wanted for other things. Greenhouse varieties, whether young or old cut-back plants that are intended for the open air, should be grown along quickly, that they may have time to develop into

the size required, and also to allow for a sojourn for a time in a cool house before they are planted outside. Excessive formality in the way of stopping, staking and tying should be avoided, and they should be planted thinly. A few nice plants showing a dwarf carpet between them make a far more acceptable bed than crowding them up together. Free-flowering varieties of sturdy habit are the best for outdoor work, the colours being selected to meet the requirements of the planter. In that section with scarlet sepals and a purple corolla I have been growing for some years a variety called Duke of Edinburgh. I was considerably surprised to see it catalogued in 1894 as a new variety at 7s. 6d. per plant. It is one of the most vigorous Fuchsias in cultivation, blooms very freely, and possesses the merit of retaining its flowers longer than many varieties. It is a capital variety grown in large pots for the summer clothing of pillars, portions of verandahs, screens, &c.

TROPEOLUMS.—The introduction of one or two new varieties of sterling merit has given an impetus to the cultivation of Tropæolums, and few gardens are now without them. Vesuvius holds its own as one of the best scarlet flowers obtainable, coming quickly into bloom and holding out well until the advent of frost. Mrs. Clibran is a very pretty shade of yellow; it will do with rather better soil than is advisable for most varieties, being of very slender habit. The trailing varieties Ball of Fire and Clibran's Gem are also good bedders; they are seen to the best advantage when planted in raised beds where they are allowed to ramble at will. A grand mass of colour is also obtainable on such beds with the aid of the old Canary Creeper. The centre of the bed may be heightened with a mound of twiggy stieks, other sticks being laid about the bed on which the plants can ramble, and the seed dibbled in the soil towards the end of April. Stronger plants that come away without a check are secured in this way than by sowing in pots and transplanting. Plenty of self-sown plants will come up from such a bed after a mild winter, but one is hardly likely to see them in the spring of 1895. Double Tropæolums, though not often used, are occasionally useful for poor dry slopes; if planted in fairly good soil, the foliage is developed to the extent of smothering the flowers. The beauty of all the tender annual Tropæolums is, however, eclipsed by the perennial *T. speciosum* if a suitable place can be found for it. If anyone has a big rough stump or a portion of a rockery to cover in a cool, moist, shady place, he cannot do better than plant *T. speciosum*. The soil should be broken up deeply, trenched in fact, and if not naturally good, better material must be added. Plant deeply and give a heavy surface mulching of short manure.

CHRYSANTHEMUM FRUTESCENS and its varieties rank amongst the best things for large beds, and would probably be more frequently seen were it not that the stock is often destroyed or so disfigured as to be practically useless by the attack of the leaf-boring fly. This pest, like many others, seems to be locally troublesome, some districts being comparatively free, whilst in others it seems almost impossible to keep clean, healthy foliage. If the stock kept through the winter is clean, the plants may be pinched and potted on, using 4-inch pots. Bi-weekly doses of liquid manure will doubtless be necessary before planting time, as the Paris Daisy is a rapid-rooting and a hungry plant. If there is the slightest sign of the insect (tiny excrescences will be perceptible on the foliage before the maggot begins its boring), clean cuttings should be obtained and the old plants burnt. In addition to their value for the open garden, these Daisies make charming vase plants if pinched in the early stage of growth to keep them well furnished throughout with foliage. One good plant will fill a vase satisfactorily, with Ball of Fire Tropæolum as an edging.

IVY-LEAF PELARGONIUMS.—Although these have been used for flower garden work in an ordinary manner for some length of time, a newer plan is to isolate them as tall specimens on a dwarfer carpet, and those readers who have not already

tried the practice will find that wonderfully pretty beds are the result of such planting. Choose sturdy autumn-struck plants, and shift at once into 4-inch pots, stake with a fairly stout cane 2 feet in length, allow three or four growths to run, and pinch at the top of the cane. The plants early in the summer will form nice little irregular pyramids, and the trailing shoots will also run along the ground and mix with the dwarfer carpet. This may be of tufted Pansies, and as the majority of the Ivies are of soft, quiet colours, there should be little difficulty in getting pleasing contrasts.

**CUPHEA PLATYCENTRA.**—An old-fashioned plant not very often seen in gardens, but holding its own against many things of more modern introduction, dwarf and compact in habit and very free flowering. A very pretty bed can be made by planting thinly alternate clumps of Heliotrope and *Centaurea ragusina*, and filling in the remainder of the bed with the *Cuphea*.

**GAZANIA SPLENDENS.**—Another old-fashioned flower very useful for any situations where the majority of plants are not satisfactory. This is a plant that amply repays a little extra care from the cutting pot. Given nice bushy stuff at planting time, it is one of the quickest growing things we have. E. BURRELL.

Claremont.

#### NOTES ON HARDY PLANTS.

**Sarracenia.**—I daresay that almost one of the first thoughts in connection with these will be their want of hardiness. I fear it is the variability of our climate that tries even the hardier varieties of this singular genus. We often have our intensest frosts without a covering of snow, and, worse still for plants with at least a measure of verdant winter foliage, often the most withering east winds. Doubtless we have yet to learn something about the best means of accommodating these plants out of doors, and should we attain the knowledge of the better treatment, it is reasonable to believe that the plants will be rendered more capable of enduring the winters. I am told that *S. flava* is one of the best plants for landscape effect in its native country. In the South American woods it forms a feature of the landscape, whole acres being covered with the showy yellow leaves 2 feet to 3 feet high. My own experience does not warrant me in saying more at present about the *Sarracenia* than that with proper treatment they are not the slow-rooting things I used to suppose. Given fresh imported roots, with a good sound piece of root-stock and a few leaves in a green state, they root rapidly in moist spongy peat liberally mixed with sand, and all the *Sarracenia* affect a somewhat shady situation. I have at present under trial some four varieties, and if these, which had become nicely established before winter, come safely through with the trifling protection of a handful of Bracken, I shall be delighted, because then I shall see no reason why they should not be planted in telling groups.

**Rhexia virginica.**—I have always treated this suspiciously for hardiness, but I think that a recent test to which a small batch of plants has been subjected fairly justifies one in not merely assuming, but affirming its hardiness. The mode and conditions were that established plants in pots, grown plunged in sand all the summer, were knocked down by the somewhat severe early frosts. The pots were then taken into a cold frame, where a few days ago along with many other things they were frozen solid, with layers of ice between the balls and the pots in the usual way that pot plants are frozen, and in the meantime there had been 22° of frost, and if one deducts 4° or 5° for the higher temperature of a frame compared with the open, we find the tubers of this beautiful Virginian plant enduring 18°. That of course is not so much as we often get, but I consider that roots with their vital parts kept so near the surface, and exposure otherwise as in the case of pot plants, they are more severely tried than open-ground plants, the degrees of cold being equal. I believe this is a point generally

conceded in relation to pot plants. One has, of course, learned to be jealous of the seeming soundness of plants and roots for a considerable time after frost-bite, and we know many instances of plants that may seem sound to the naked eye at their vital parts for weeks after the frost has gone, but were such plants closely scrutinised by the aid of knife and lens, it would soon be seen whether rupture of tissue had occurred. I will only add that in the case of the *Rhexia* it proves sound after careful examination subsequent to the above-described attacks of frost.

**Brachycome Sinclairi.**—A curious bit of experience has accidentally occurred with this plant. It is known that this somewhat rare plant is rather tender, and though as a rare and beautiful plant it merits some care, yet because of its doubtful hardiness it has not here for the last few years received more attention than to have given it the shelter of a cold frame plunged in fibre, and, oddly enough, under these conditions it has lived and sprung up from self-sown seed. The curious experience comes in this way: I thought I would nurse the best plant I had and place it in a cool greenhouse near a slight opening, so as not to lack air or to become over-drawn. During the 25° of frost we have just experienced, immediately around the opening I noticed the plants were frost-bitten this morning, and whilst the *Odontoglossums* seemed no worse for the nip, the foliage of *Brachycome* seems totally destroyed. No doubt the previous warmth of the greenhouse had rendered it more tender, and, likely enough, the extreme pubescence of the plant would make the frost tell with all the more effect. Moral: Had this plant been left in the cold frame as before, it would no doubt, as of yore, proved a flourishing plant in April or May. The above facts are simple, it is true, but who knows the value of facts better, and who could profit more by them than the gardener?

**Soldanellas.**—My own experience is, that though seedlings can be easily raised and grown on to fine-flowering plants in two years, their vigour is not more than that of older plants. In other words, I do not consider these plants should be classed with certain perennials that are known to be better raised every year from seed with the object of keeping up a succession of vigorous young plants. From my experience, may I again repeat, and I ought, perhaps, also to say that here the *Soldanellas* all do well, as it would obviously be misleading to quote test cases of plants where something prevented their flourishing, that very old plants do remarkably well, and present themselves in such a desirable form as no seedlings of two or even three years could. But these results are certainly not had by a "left-alone" treatment exactly. My treatment is to top-dress them liberally with sand and peat or sand and leaf-mould, on the principle that both by the action of frost in winter and the way in which, like other primulaceous plants, the crowns and roots elevate themselves above the surface, so that in time, unless top-dressed, they become dried up and dwindle. Moreover, I believe that if wildings are examined they will be found to be flourishing in those positions where they receive periodically coverings of soil from the higher ground, and anyone can satisfy himself that it is the habit of these humble plants to so elongate their rhizomes or root-stocks, that they must inevitably die did they not by either natural or artificial means receive timely coverings. I am therefore quite sure that anyone will get better results by cultivating into large masses old stock compared with seedlings, though I by no means wish to discourage seed-propagation.

**Campanula valdensis** (Alph. de C.).—To go into the authorities for this name and its place botanically presents one of the instances of authorised confusion, or confusion of authorities. It is shown to be a variety of *linifolia* (of Lam.), while *linifolia* itself is made a variety of *rotundifolia* by Lapeyr. and also by Wahl. Again, it is given as a species (All.), and it has no less than three or four synonyms, which, with all deference

to the authorities, I will not write here. The plant may not be described as a minute form of *caespitosa*, but minutely examined might be imagined to have a near relationship to *pulla* and *Waldsteiniana*. Its flowers, however, are very pale, but so shell-like in substance, as to rattle when dashed in the hand. Though at a glance it might strongly remind one of *pusilla*, closely examined it will be found to be a much more refined Bellwort. It grows but 2 inches or 3 inches high, smothers itself with pale puce bells, and has a moderate habit of spreading at the root. It is one of those sweet little things that one may cram into the loamy seams of a sunny rockery, and that may be repeated almost all over the garden with pleasing effect; or, to put it another way, it is one of those spreading *Campanulas* that one could hardly ever tire of. And did one do so, it is more easily eradicated than some of the deeper rooters. It might be suggested as a pretty carpet or foil for late summer and autumn flowering bulbs, not the earlier ones of spring, because then it is defoliated. Speaking of

**Campanula pusilla**, there are two *Campanulas* of this name, but, fortunately, once known they cannot be mistaken. One is the generally known pretty creeper of Haenk and the other is authorised by Alph. de C. as a variety of *glomerata*, one of our British species.

**Daphne rupestris.**—I have had occasion of late to seek out the authority for this name, and as it did not prove to be one of the most readily found, it may be useful to mention the information I gleaned from the Rev. Mr. Wolley-Dod and other sources. The authority for the name *rupestris* is *Facebias*. The plant is identical with *D. petraea* of Leybold. It would seem that this Tyrolean plant has been added to the flora of Europe within comparatively recent years. It is unnecessary to point out that though two such names as *petraea* and *rupestris* may have synonymous meanings, they may seldom refer to the same plant when used by two different authorities, as they do, however, in this case. If this pigmy shrub has been described, I should be grateful to anyone who would refer me to the description.

**Hypericum balearicum.**—Whether seen in the form of a herbarium specimen or in a living state this species is at once a remarkable and beautiful plant. Until lately I must confess that I had looked on it as considerably wanting in hardiness as an open-air plant for Yorkshire. Latterly, however, in correspondence with a friend, I have received assurances that it may be grown and kept going like several of the common St. John's Worts. I attach much importance to this, because if it should prove hardy, it must be a deeply interesting as well as an attractive plant. We are told in Curtis' "Magazine" that the plant is for hardy greenhouse, but without egotism we may claim to know a little more now-a-days as to the capabilities of old species like the present. Some of the interest about the plant comes in when we study the old name for it of *Clusius*, which, however unfitting from the present-day botanist's point of view, was significant and expressive to a degree, namely, *Myrto-Cistus Pennai*, from "the leaves being somewhat like those of the Myrtle and a gummy substance exuding from the plant as in the *Gum Cistus*." The distinctive beauty of the shrub is seen in the erect and rigid stems of a ruddy colour, which are also, with the yellowish green, lobed, and wrinkled leaves, of a rigid texture, freely beset with warty developments. For the size of the plant, the flowers are large and gay, and altogether a two or three-year-old specimen cannot fail to win admiration. It is very easily propagated by cuttings of the new wood in summer out of doors or at any time in the greenhouse. J. Wood.

Woodrill, Kirkstall.

**Lilium Browni.**—Judging by the splendid bulbs of this Lily sent here by some of the Dutch cultivators, it does well in Holland, and when in flower is certainly very beautiful. The illustration of the typical *L. Browni* (accompanying the

coloured plate of the variety *leucanthum*) on page 97 of THE GARDEN is a very truthful representation of this beautiful Lily, the distinct, long arching foliage being well shown. The variety *odorum* mentioned on the same page is, as a garden plant, inferior to the type, and it is also far more delicate in constitution. This is frequently offered for sale in the London auction rooms during the winter under the name of *Lilium japonicum Colehesteri*, and fine bulbs can at times be obtained at a moderate rate. Very large-sized bulbs from 11 inches to 13 inches in diameter are, I see, offered in the catalogue of one of our large importers, and such as these should yield a good display of bloom. The typical *Lilium Browni* does well in pots, though it is not often seen so treated. When so grown and required for the greenhouse or conservatory it should be kept out-of-doors till the flowers are on the point of expanding, as in a sunny spot the chocolate-tinted exterior is much more pronounced than if it is grown altogether under glass. An especially striking feature of this Lily is the marked contrast between the ivory white of the interior and the deep chocolate-tinted outside of the flower.—H. P.

#### FOLIAGE PLANTS IN WINTER ON THE ROCKERY, &c.

THE articles recently published in THE GARDEN on this subject are most interesting, and it would be quite possible, with the wealth of material we have, to make a most interesting winter garden alone. I have noted the following as desirable for that purpose: *Andromeda tetragona* is distinct in its vivid green; *A. polifolia*, *A. p. major* and *A. p. minor* are charming in their degrees of bronzing, the latter particularly so; *A. calyculata*, of taller growth, is very distinct; while *A. Mariana* still retains many of its richly-coloured leaves. These standing, as they recently did, above the snow had a very quaint appearance. *A. racemosa* retains most of its leaves, and they are almost purple. *Azalea procumbens* is a compact mass of reddish bronze, while *Thymus serpyllum coccineus* is of even a deeper colour. *Frankenia laevis* is the deepest green thing in the garden; this is a most excellent carpeting plant. *Galax aphylla* is beautiful in its various shades of green to red; while *G. a. macrophylla*, with much larger leaves, scarcely changes from green at all. *Aubrieta purpurea aurea variegata*, rich in its yellow margining, is very showy, and as many of its shoots are often entirely yellow, it looks in the distance like a plant in flower. The old and not now often seen *A. p. albo-variegata* is also a very good plant. A good, but much smaller thing is *A. anti-Libani marmorata*. In this the tiny crowded leaves are entirely marbled with white. *Erica carnea* is already a mass of rosy buds, while *Alyssum alpestre* forms closely creeping masses of silver. *Gaultheria procumbens* is well known and excellent in its glossy greenness; while *G. nummularia* is of quite another type of growth; it forms thick masses of rather dull green leaves and russet stems, with here and there leaves of a bronzy tint. *Hepatica acutiloba* has beautifully marbled leaves, quite different to those of *H. triloba*; they are also more prostrate in habit. In damp places *Helonias bullata* is most distinct, rich clumps of luxuriant green changing to bronzy red. *Ledum latifolium compactum* is a mass of old bronze. *Megasea Croesus* is the only one not badly hurt by the frost, while it is the smallest of them all, the leaves not much more than 3 inches across and rich bronze and red. The two *Aciphyllas*, *Colensoi* and *Lyalli*, are very distinct, the former vivid green and the latter a curious rusty grey. *Berberis buxifolia nana* is a good and distinct shrub. The various Heaths are a power in themselves. *Menziesia polifolia* is good, and the distinction in colour between the white and the purple kinds is very marked. *M. empetrifolia* is very distinct. *Cassinia fulvida*, not hurt in the least by the cold, is beautiful in its golden sheen:

while last, but by no means least, *Tellima grandiflora rubra* provides the ruddiest masses in the garden. T. SMITH.

*Newsp.*

## TREES AND SHRUBS.

### SPIRÆA ARLEFOLIA.

THE most graceful of all the Spiræas—*S. arifolia*—is herein depicted, the illustration showing well not only its elegant habit, but also how free-flowering a thriving specimen is. It is one of the largest-growing members of the genus, for it will reach a height of 10 feet to 12 feet, and even more, while the plume-like panicles of creamy white blossoms are at their best, as a rule, towards the latter part of June and in July. As an

*Spiræa arifolia*. Engraved for THE GARDEN from a photograph sent by the Rev. W. J. Gerard, The Rectory, Rathangan, Co. Kildare, Ireland.

isolated specimen it is seen to very great advantage, and just standing out prominently from other shrubs, which serve to form a background, there is no more beautiful picture than is furnished by this Spiræa. It is a native of North-west America, and was introduced into this country in 1827. Though so long known under the name of *S. arifolia*, it is now by the botanical authorities named *S. discolor*. In any selection of the best Spiræas this is undoubtedly entitled to a foremost place. Though its height is as above stated, it will flower well long before it attains these dimensions.

T.

**Rubus australis.**—This has lately been brought before the notice of your readers, and rightly too, as it is such a distinct Bramble that it attracts the notice of all who see it. I should hardly have troubled you to say more in its favour than has been said, but 1893 being such a dry year at this place and the unusual growth this shrub

made showed how much it enjoyed a dry summer. It has been growing here unprotected for many years, planted on a mound and allowed to grow at will between and over rock boulders. During the summer of 1893 it made growths 12 feet long, much longer than usual, showing how much it enjoyed a dry season and situation.—W. O., *Fota*.

**Forsythias under glass.**—The two Forsythias, *F. suspensa* and *F. viridissima*, were grown in our gardens for many years before advantage was taken of their naturally early flowering qualities to furnish the greenhouse. They both readily lend themselves to gentle forcing, and in the greenhouse are very beautiful before winter has left us. Of the two I prefer *F. suspensa*, which is naturally of a loose, rambling style of growth—in fact almost a climber, while *F. viridissima* forms a sturdy-growing free-branched bush. If a plant of *F. suspensa* be secured to a stick and the slender flexible branches allowed to dispose themselves at will, it forms a really graceful specimen, and when all these drooping shoots are studded with yellow blossoms they have the appearance of a shower of gold. *F. viridissima* is under the same treatment very pretty, but it is wanting in the grace and elegance of the other. There are few of our hardy shrubs that can advantageously be employed for so many distinct purposes as *Forsythia suspensa*, for, as above noted, it forces well; then, planted in the open ground and allowed to grow at will, it is very attractive, while for furnishing a wall it is unsurpassed among deciduous subjects. Next, owing to its thorough hardiness, it can be used for covering a fence or any similar purpose where anything at all tender would not stand, for an open fence, owing to the draught through it, does not yield anything like the same amount of protection as a wall. *F. suspensa* is very much given to root at the tips of the branches like a Bramble, so that in the case of a plant standing in the open ground under conditions favourable to the production of roots, a colony of young plants will in time be formed all around it.—T.

**The Maiden-hair Tree.**—*Salisburia adiantifolia*, certainly a more euphonious name than *Ginkgo biloba*, although introduced into this country so far back as 1740, does not seem to have found much favour with planters, a rather remarkable circumstance when we consider that it is an absolutely unique tree. Many exotics resemble in foliage either a fellow foreigner from some other country, and in some instances our own native trees, but this cannot be said of the *Salisburia*. Also it may be claimed in its favour that it is equally as beautiful. The *Umbrella Pine* for instance, also a Japanese tree, is very distinct, but it can hardly be pronounced a beautiful tree. It may, I think, be safely asserted of the *Salisburia* that it is admirably adapted for any site where a deciduous tree of average size is required. It may with advantage find a place in any ornamental planting and should be assigned a prominent position. Attention has been directed to the fact that it is a fine autumn tree, the decaying foliage very clear and pronounced in tint, and it may also be noted that the foliage is retained a considerable time, as many exotic trees, if a sharp early frost comes, are often completely stripped in twenty-four hours. The *Maiden-hair Tree* has the reputation of being of very slow growth for many years in its early stages, a fact I am not able to
